The Conservation and Survey Division of the University is the agency designated by statute to investigate and interpret the geologically related natural resources of the state, to make available to the public the results of these investigations, and to assist in the development and conservation of these resources.

The Division is authorized to enter into agreements with federal agencies to engage in cooperative surveys and investigations in the state. Publications of the Division and the cooperating agencies are available from the Conservation and Survey Division, University of Nebraska, Lincoln 68508.

Publications and price lists are furnished upon request.

WATER LEVELS IN OBSERVATION WELLS IN NEBRASKA IN 1968

INTRODUCTION

A ground-water reservoir consists of saturated rock materials sufficiently permeable that water can move through them by gravity and can be discharged through wells. Under natural conditions, water enters ground-water reservoirs by percolation from the land surface and then very slowly moves laterally within the reservoir toward areas where it discharges by evapotranspiration, flow from springs, or seepage into lakes or streams.

The amount of water stored in ground-water reservoirs differs from time to time owing to the ever-changing relationship of recharge to discharge. Such changes in the amount of water stored are reflected by fluctuations of the water level in wells. Where little or no ground water is discharged through wells, water-level fluctuations are governed almost wholly by natural recharge to and natural discharge from the ground-water reservoir; where much ground water is discharged through wells, water levels adjust to reflect effects of pumping. By measuring water levels in wells periodically and by plotting the measurements against time, it is possible to project the trend of water-level fluctuations and to estimate the adequacy of future water supplies.

Water levels in many observation wells in Nebraska have been measured for more than 20 years, and some have been measured since 1934; however, new wells are continually being added to the program and some are inadvertently destroyed or dropped from the program for some reason. Measurements made during 1968 in wells not included in this report may be obtained from the U.S. Geological Survey, Room 127, Nebraska Hall, 901 North 17th Street, Lincoln, Nebr., 68508, or the Conservation and Survey Division, University of Nebraska, Lincoln, Nebr., 68508, upon request.

Except for a few, the water-level measurements given in this report are made in the fall after the close of the irrigation season. All measurements are in feet below land-surface datum at well sites. Land-surface datum is a datum plane that is approximately at land surface at each well. Water levels above land-surface datum are preceded by a plus (+) sign, whereas those below have no sign but are understood to be minus (-).

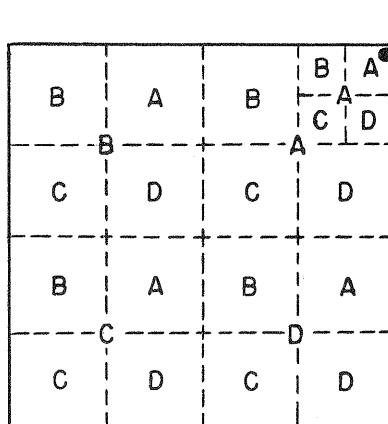

B. H. Ringen of the U.S. Geological Survey and G. R. Svoboda of the Conservation and Survey Division of the University of Nebraska jointly directed the statewide observation-well program during 1968. The following organizations cooperated informally in the program by furnishing records for some of the wells: Nebraska Mid-State Reclamation District; U.S. Bureau of Reclamation; U.S. Bureau of Sport Fisheries and Wildlife; Nebraska Department of Water Resources; Nebraska Department of Roads; Department of Public Works and Utilities, City of Lincoln; and various county and district organizations.

WELL-NUMBERING SYSTEM

Well numbers are based on the land subdivisions within the U.S. Bureau of Land Management's survey of Nebraska. The numeral preceding the N (north) indicates the township, the numeral preceding the E (east) or W (west) indicates the range, and the numeral preceding the terminal letters indicates the section in which the well is located. The terminal letters denote, in order, the quarter section, the quarter-quarter section, and the quarter-quarter-quarter section and are assigned in counterclockwise direction beginning with A in the northeast quarter of the section, of the quarter section, and of the quarter-quarter section.

If two or more wells are located in the same tract, they are distinguished by appending a sequential digit to the well number. (See accompanying sketch.) Thus, the second well inventoried in NE $\frac{1}{4}$ NE $\frac{1}{4}$ NE $\frac{1}{4}$ sec. 26, T. 4 N., R. 7 W. would be assigned the number 4N-7W-26AAA2.

WELL NO. 4N-7W-26AAA

Section 26

PRECIPITATION

During 1968 precipitation over the State averaged 1.12 inches greater than normal; only the Southwest Division of the State was below average. January, February, and March were very dry in all parts of the State whereas precipitation during the spring and early summer was near normal and during summer and fall was generally above normal except in the southwest. The distribution of the summer rainfall was more favorable for crop growth than in the average year, and many irrigation wells in southeastern Nebraska were not pumped after the end of July. The summer rains probably added only a small amount of recharge to the ground-water reservoir, but they reduced the withdrawals for irrigation.

Graphs of the cumulative average precipitation for each of the eight climatic divisions of the State are shown in figure 1. The dashed line is the cumulative average monthly precipitation for 1968, and the solid line is the cumulative average monthly precipitation for the 30-year period of record. Precipitation differed from the long-term average by the amount of deviation of the curves.

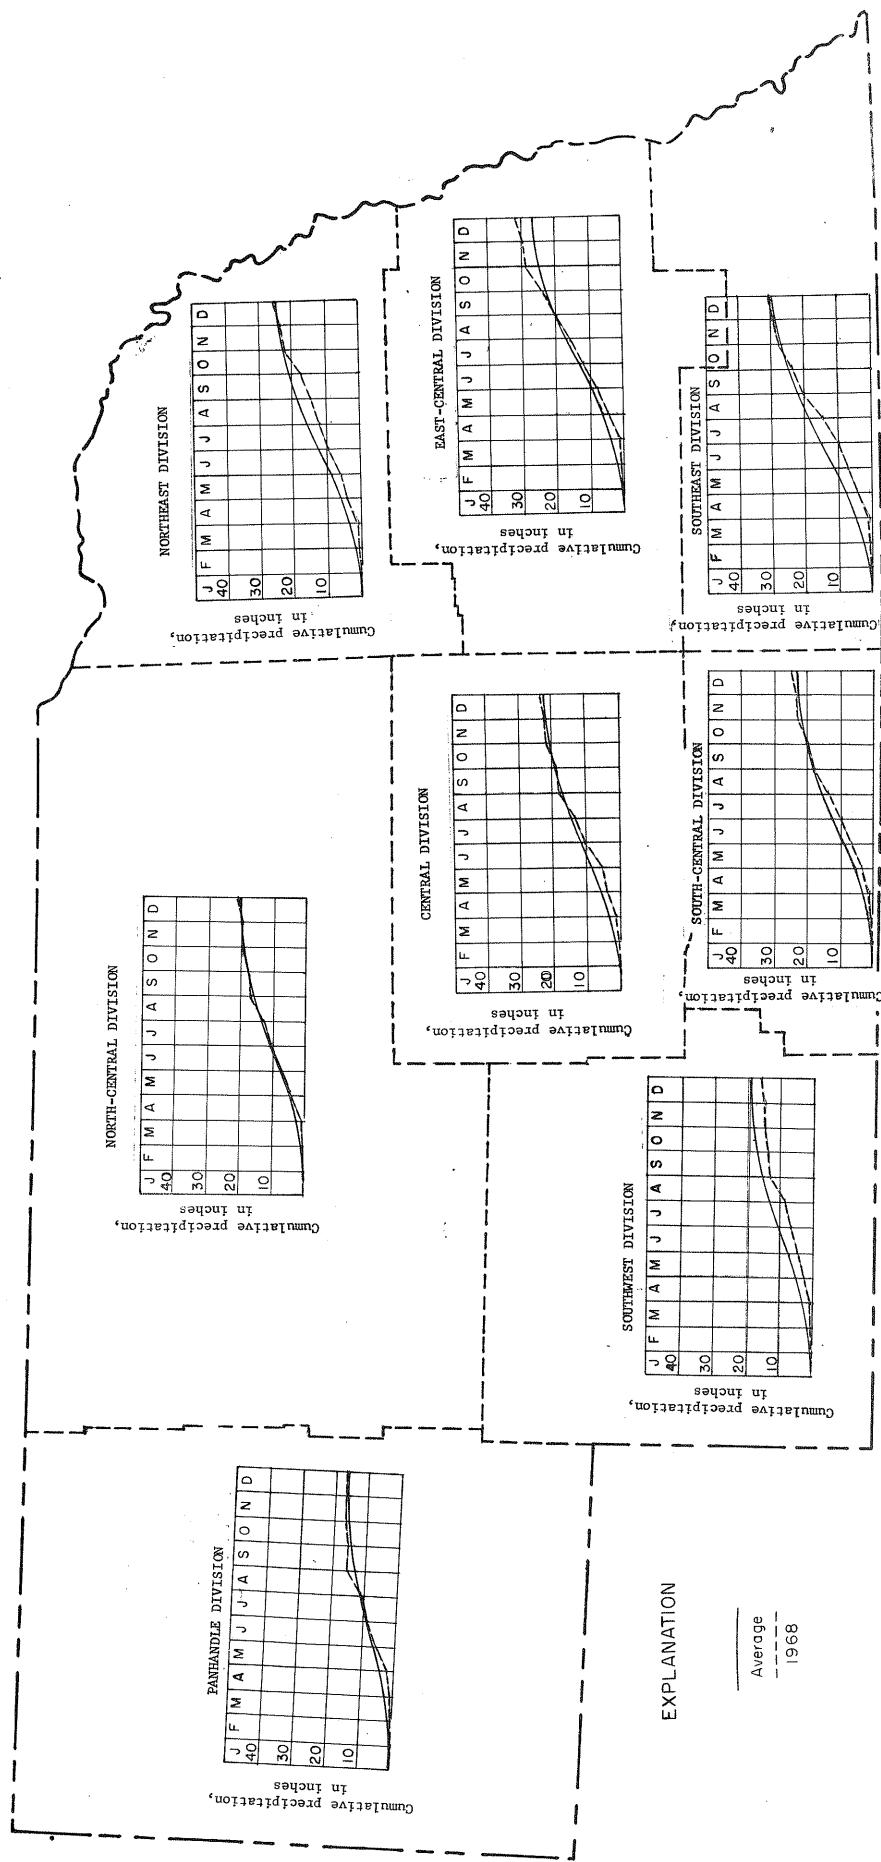

Figure 1--Map of Nebraska showing cumulative average monthly precipitation and cumulative monthly precipitation for 1968 in eight divisions of the State.
(From records of the ESSA Weather Bureau)

WATER-LEVEL FLUCTUATIONS

Periodic measurement of depth to water in wells provides information on fluctuations of the water table; and when observations are continued through a long period of time, trends in storage changes of the ground-water reservoir are indicated. At places where continuous records of water-level fluctuations are desired, observation wells are equipped with recording gages. Such gages record all water-level changes automatically; thus, the gage chart is a continuous record of the magnitude and frequency of the fluctuations.

In areas where little or no water is withdrawn from ground-water reservoirs, water levels in observation wells indicate the natural trend of changes in ground-water storage. On the other hand, in areas where much ground water is pumped for irrigation or other uses, the natural forces influencing fluctuations of water levels generally are overshadowed by effects of pumping. When wells are pumped heavily, levels may decline substantially because water is being removed faster than the ground-water reservoir discharges it naturally. After the irrigation season ends and wells are no longer pumped, water levels recover somewhat but normally do not rise to the prepumping level. Figure 2 shows the number of irrigation wells registered in each county by fall 1968 and the number registered during the year. Of the 32,430 registered irrigation wells in the State as of January 1, 1969, 1801 were registered in 1968 with the Nebraska Department of Water Resources.

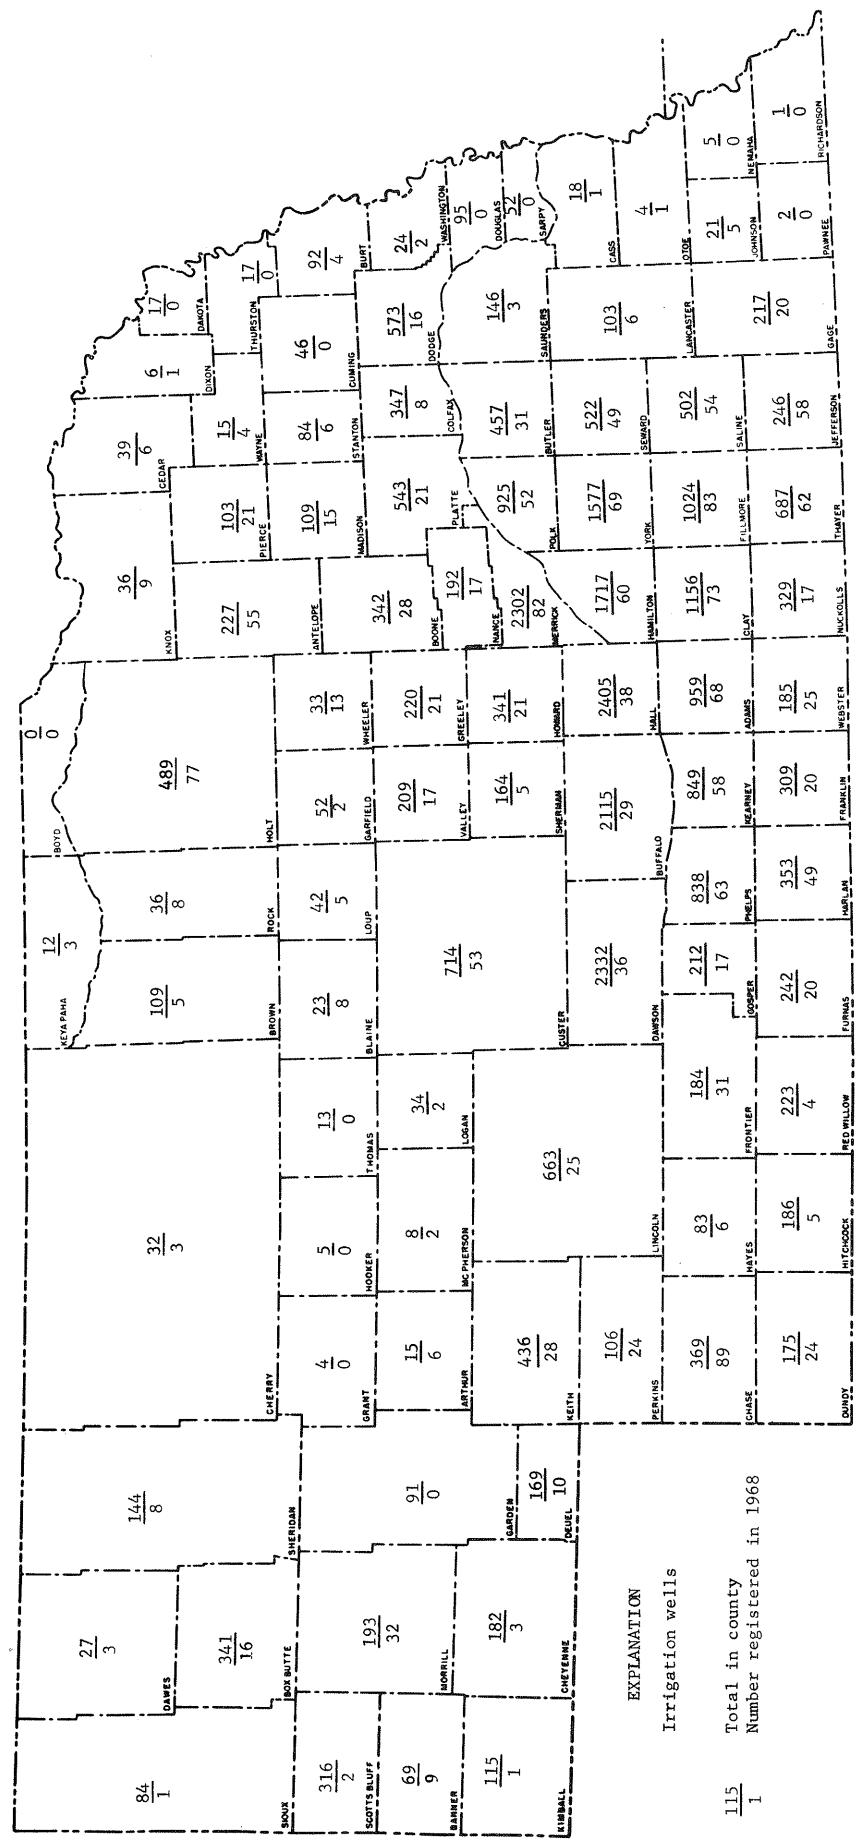

Figure 2.--Map of Nebraska showing the number of registered irrigation wells in each county by the end of 1968 and the number registered during that year.
 (From records of the Nebraska Department of Water Resources)

CHANGES IN WATER LEVELS

Sixty of the 93 counties in the State ended the 1968 year with average water levels lower than those in the fall of 1967. Most counties that had rising water levels were those where surface water is diverted from streams for irrigation, recharge to the ground-water reservoir from the irrigation-water seepage accounting for the rise in water levels. In a few counties, however, water levels showed a net rise because recharge from greater than normal precipitation in late summer more than balanced the discharge during the year. Among these were the following counties in the Big Blue River basin: Clay, with an average water-level rise of 1.28 feet; Hamilton, with a rise of 0.48 foot; York, with a rise of 0.32 foot; and Polk, with a rise of 0.11 foot. All other counties in the Big Blue basin sustained a net decline in average water levels during the year. Similarly, water levels in the lower Platte River valley were a fraction of a foot lower than in the fall of 1967 except in Hall County, where the average rise was about 0.7 foot.

All counties having significant water-level declines were those where ground water is heavily developed. The development in Holt County is beginning to lower ground-water levels, the average decline there being 1.68 feet and the greatest decline in a single well 9.06 feet. Withdrawals of ground water in Box Butte County resulted in an average decline of 1.04 feet during 1968.

Figure 3 shows for 91 of the 93 counties how much the average fall 1968 water-level readings differ from the average of the previous fall and from the assumed normal or predevelopment level. Derivation of the assumed normal for any well added to the observation-well program involves interpretation of the history of water-table changes in the vicinity of the well, based on long-term records of water-level fluctuations in that vicinity. Not all records are long, but a few are longer than 30 years and many are longer than 20 years. Although a predevelopment water level cannot be precisely determined for a new well, the assumed normal affords a meaningful reference datum to which all future water-level readings can be compared when evaluating the effects of water-use developments.

Areas where the water table has risen or declined 5 feet or more during the period of record are shown in figure 4. The greatest rise has occurred in Gosper, Phelps, and Kearney Counties where recharge from the "Tri-County" irrigation development has raised the water table more than 50 feet along the axis of the water-table divide between the Platte and Republican Rivers. Significant declines have occurred in Box Butte County and in the Big Blue River basin (Polk, Hamilton, York, Adams, Clay, and Fillmore Counties). Figure 5 shows how the water level in well 6N-15W-1CB (Kearney County) has risen as a result of seepage from irrigation water and figure 6 shows how the water level in well 25N-48W-4DDD1 (Box Butte County) has declined 24 feet since the early 1950's owing to withdrawals for irrigation. The greatest decline due to pumping for irrigation in the Big Blue River basin was nearly 21 feet in well 7N-4W-17BD1.

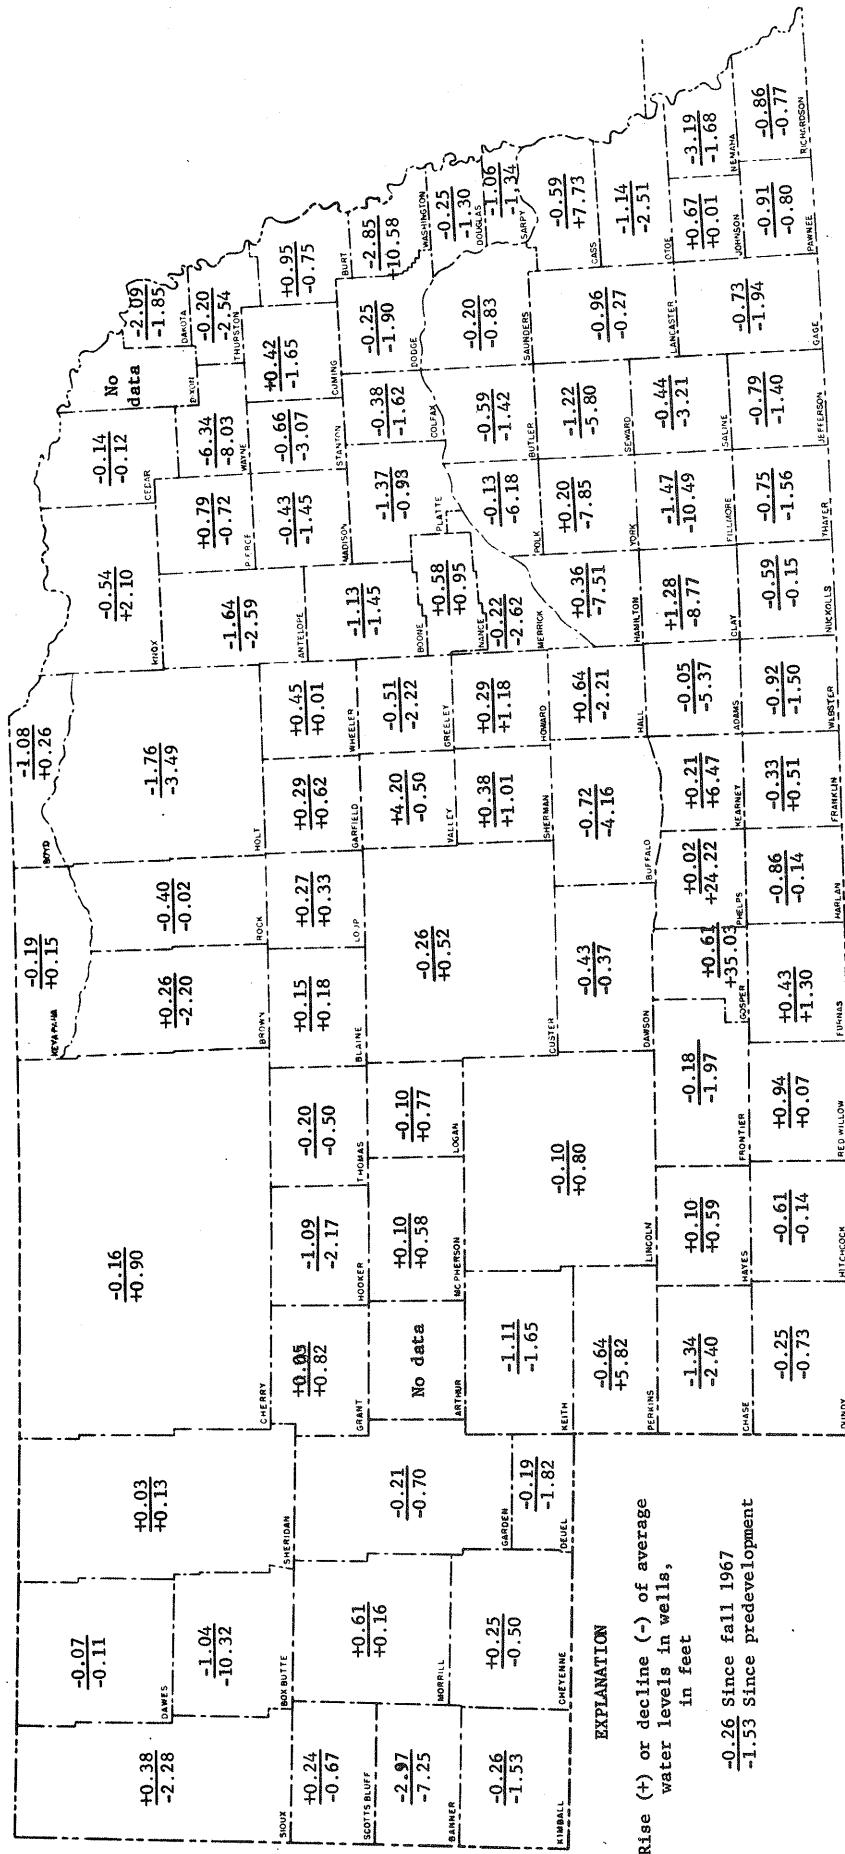

Figure 3.—Map of Nebraska comparing the average Fall 1968 water-level position in wells with the average Fall 1967 and predevelopment positions in each county.

NEBRASKA

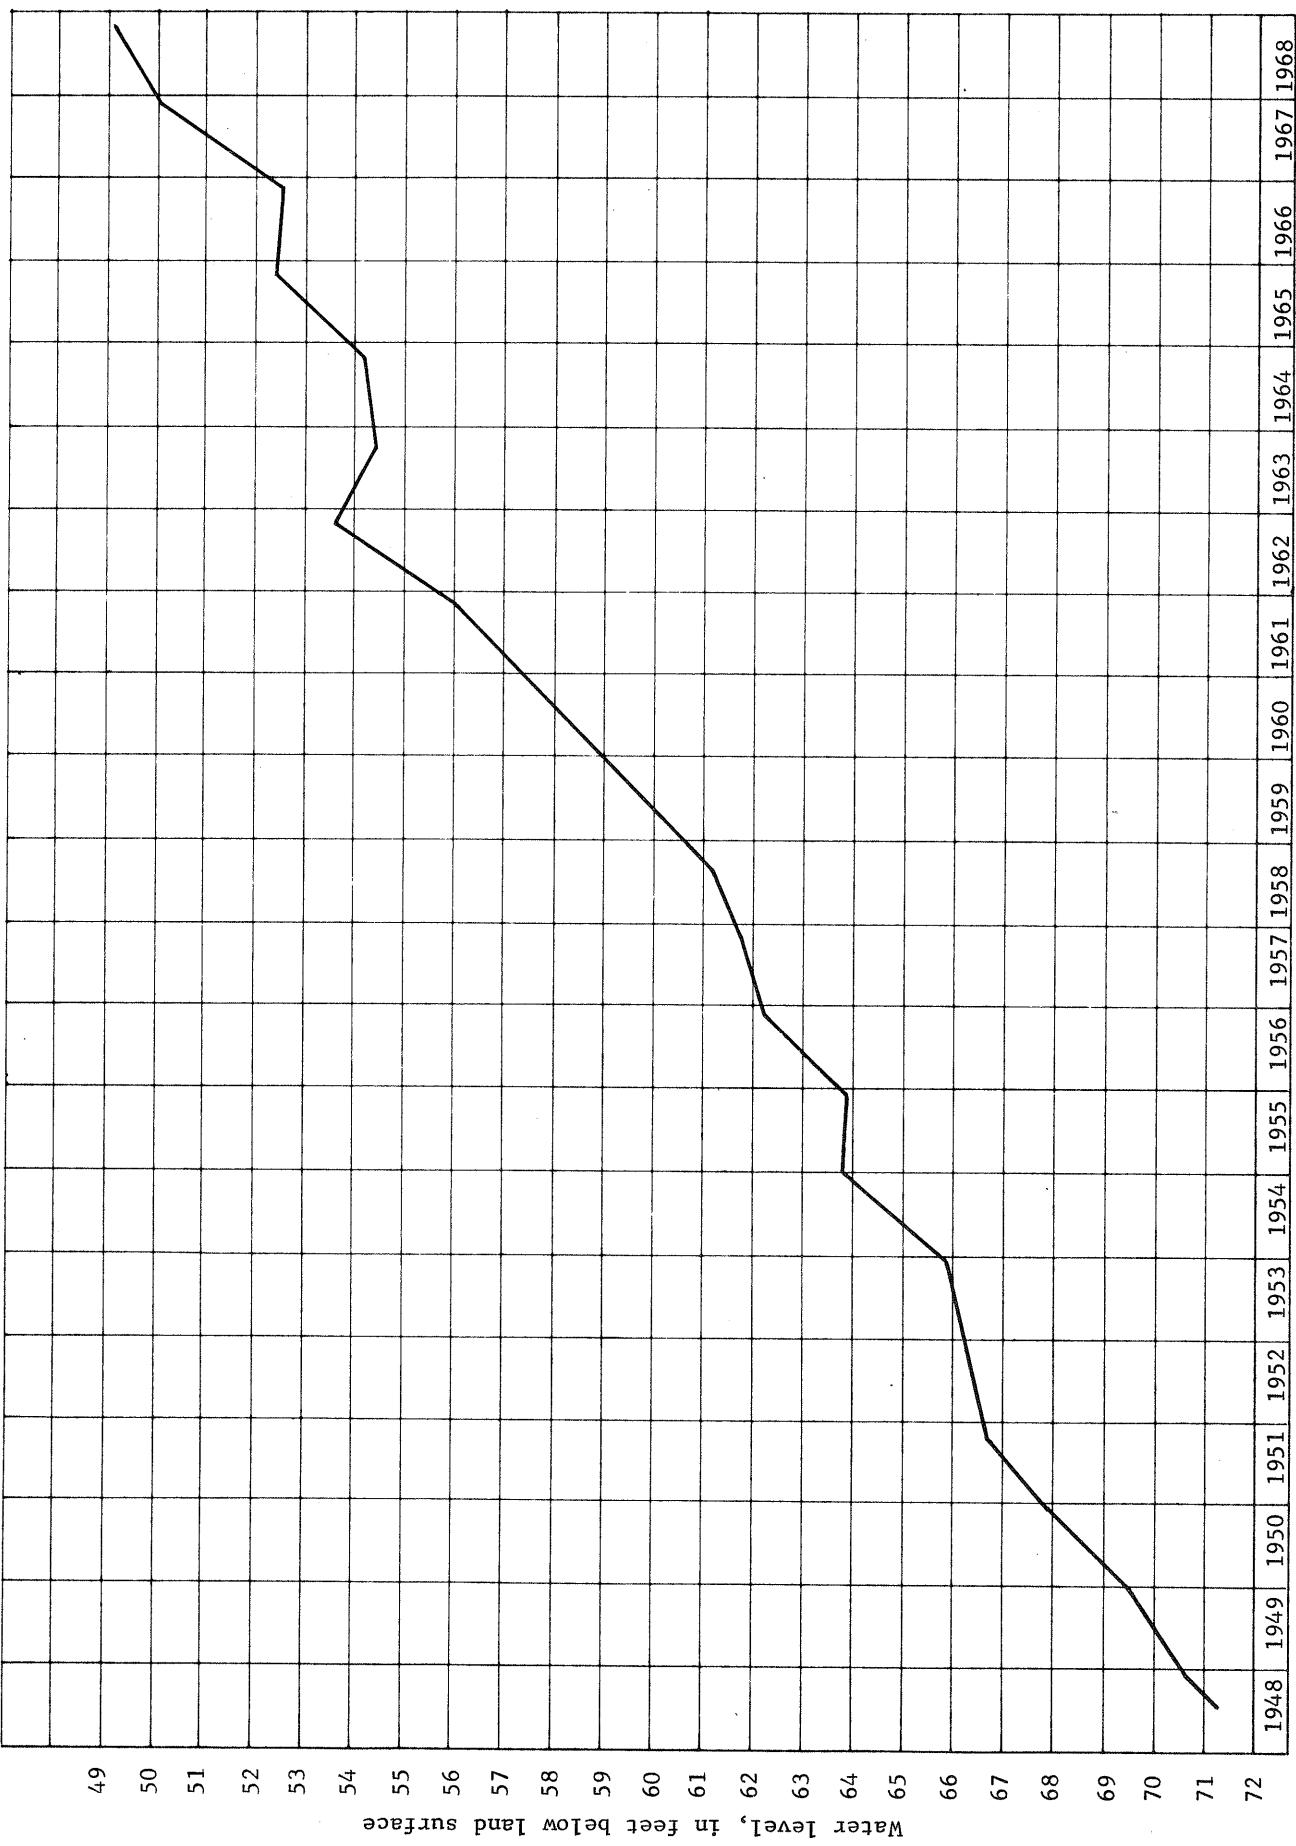

Figure 5.--Hydrograph of water-level fluctuations in observation well 6N-15W-1CB, Kearney County, Nebr.

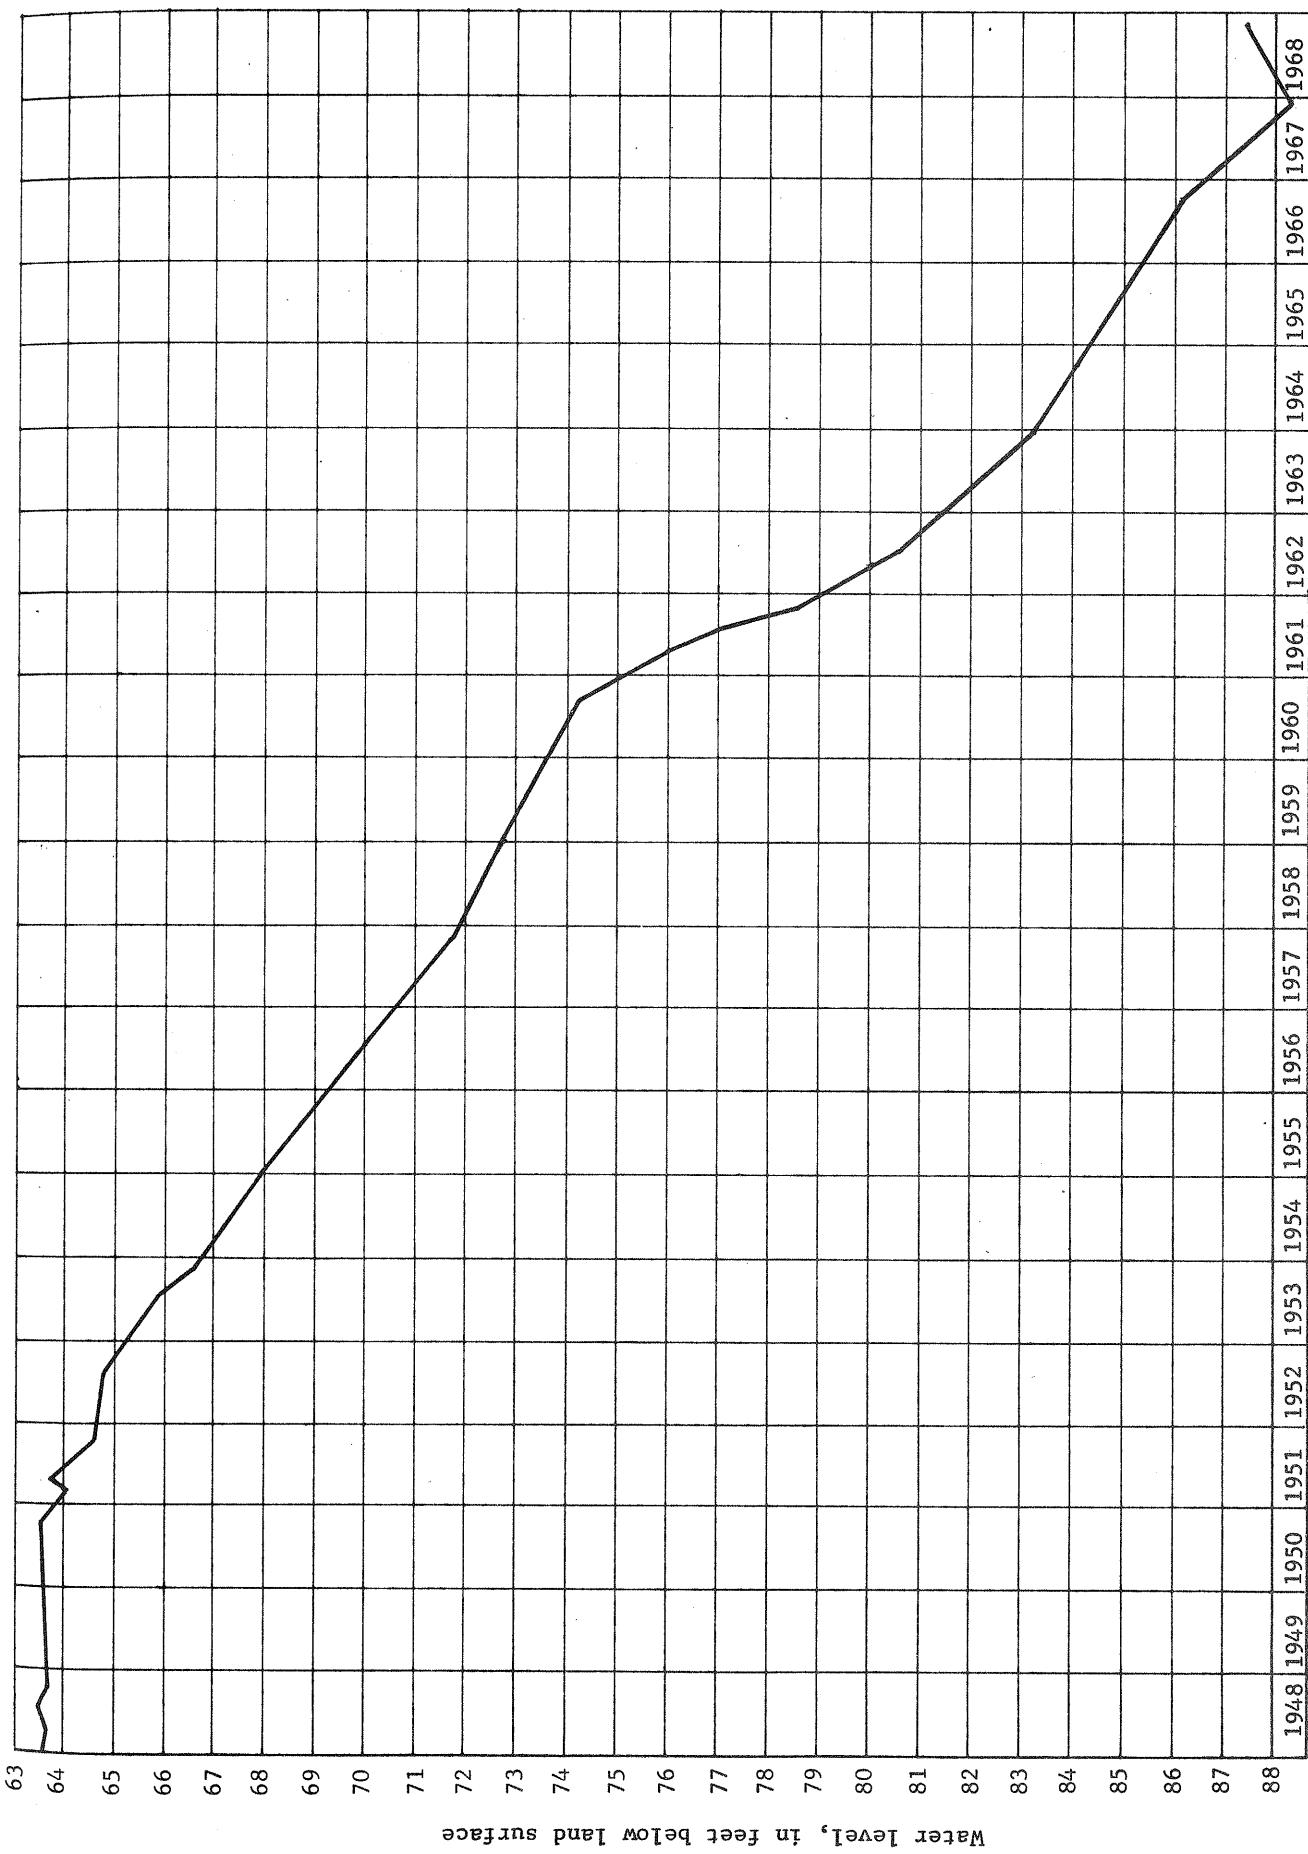

Figure 6. --Hydrograph of water-level fluctuations in observation well 25N-48W-4DDI, Box Butte County, Nebr.

During the summer and fall of 1968, 20 new recording gages were added to the network of 27 that had previously been installed and operated. Records for recently installed recorders are not included in this report but will be published in future reports. Locations of all recording gages, including those recently installed, are shown on the map. Hydrographs for the gages for which records have been published follow page 43; they are arranged alphabetically according to the name of the county in which each is located. Some of the graphs show a long-term downward trend indicating that the rate of ground-water withdrawal is greater than the rate of natural discharge. Others have a long-term upward trend indicating that recharge is occurring at a rate greater than withdrawals and natural discharge combined.

OTHER REPORTS CONTAINING WATER-LEVEL MEASUREMENTS

The publication of measurements of water levels in wells in the United States was begun by the Geological Survey in 1935 and was continued annually until 1957. Data collected after that time have been presented at 5-year intervals. Records for representative Nebraska wells are included in the U.S. Geological Survey publications listed in the following table.

U.S. Geological Survey Water-Supply Papers on Water Levels and Artesian Pressures in Observation Wells in the United States

Year	Number	Year	Number	Year	Number
1935	777	1943	988	1951	1193
1936	817	1944	1018	1952	1223
1937	840	1945	1025	1953	1267
1938	845	1946	1073	1954	1323
1939	886	1947	1098	1955	1406
1940	908	1948	1128	1956	1456

1942	946	1950	1167		

Beginning in 1954, annual publications of the water-level measurements made in wells in Nebraska were released in State reports. Except for some wells observed during special studies, on which records are kept in open file, these reports include water-level data for all observation wells in the Nebraska network. The annual State water-level reports are listed below.

Keech, C. F., and Case, R. L., 1954, Water levels prior to January 1, 1954, in observation wells in Nebraska, Pts. 1 and 2: U.S. Geol. Survey open-file rept., Washington, D. C., Denver, Colo., and Lincoln, Nebr.
