Scherer, B., Moser, E. A., Brown, J. W., Rodefeld, M. D., Turrentine, M. W., & Mastropietro, C. W. (2016). Vasoactive-ventilation-renal score reliably predicts hospital length of stay after surgery for congenital heart disease. *The Journal of thoracic and cardiovascular surgery*, 152(5), 1423-1429. <http://doi.org/10.1016/j.jtcvs.2016.07.070>

52 **Glossary of Abbreviations**

53 **AUC:** area under the receiver operating characteristic curve

54 **CI:** confidence interval

55 **CPR:** cardiopulmonary resuscitation

56 **CVICU:** cardiovascular intensive care unit

57 **ΔCr:** change in serum creatinine from baseline

58 **ECMO:** extracorporeal membrane oxygenation

59 **FiO<sub>2</sub>:** fraction of inspired oxygen

60 **ICU:** intensive care unit

61 **LOS:** length of stay

62 **IQR:** interquartile range

63 **MAP:** mean airway pressure

64 **OR:** odds ratio

65 **PEEP:** positive end expiratory pressure

66 **PIP:** peak inspiratory pressure

67 **ROC:** receiver operating characteristic

68 **RR:** respiratory rate

69 **STAT category:** Society of Thoracic Surgeons-European Association for Cardio-

70 Thoracic Surgery Congenital Heart Surgery mortality category

71 **VI:** ventilation index

72 **VIS:** vasoactive-inotrope score

73 **VVR:** vasoactive-ventilation-renal score

74

75

76

77

78 **Abstract**

79 **Objectives:** We aimed to further validate the vasoactive-ventilation-renal score (VVR)  
80 as a predictor of outcome in patients recovering from surgery for congenital heart  
81 disease. We also sought to determine the optimal time point within the early recovery  
82 period at which the VVR should be measured.

83 **Methods:** We prospectively reviewed consecutive patients recovering from cardiac  
84 surgery within our ICU between 1/2015 – 6/2015. The VVR was calculated at 6, 12, 24,  
85 and 48 hours postoperatively as follows:  $VVR = \text{ventilation index} + \text{vasoactive-inotrope}$   
86  $\text{score} + \Delta \text{creatinine} [\text{change in serum creatinine from baseline} * 10]$ . Primary outcome of  
87 interest was prolonged hospital length of stay (LOS), defined as LOS in the upper 25%.  
88 Receiver operating characteristic curves were generated and areas under the curve  
89 (AUC) with 95% confidence intervals (CI) were calculated for all time points.  
90 Multivariable logistic regression modelling was also performed.

91 **Results:** We reviewed 164 patients, median age 9.25 months (interquartile range: 2.6 -  
92 58 months). Median LOS was 8 days (interquartile range: 5 - 17.5 days). The AUC  
93 value for the VVR as a predictor of prolonged LOS (>17.5 days) was greatest at 12  
94 hours postoperatively,  $AUC=0.93$  (95% CI: 0.89 - 0.97). On multivariable regression  
95 analysis, after adjustment for potential confounders, the 12-hour VVR remained a strong  
96 predictor of prolonged hospital LOS (OR: 1.15, 95% CI: 1.10, 1.20)

97 **Conclusions:** In a heterogeneous population of patients undergoing surgery for  
98 congenital heart disease, the novel VVR calculated in the early postoperative recovery  
99 period can be a strong predictor of prolonged hospital LOS.

**130 Perspective Statement**

131 In this prospective study of patients undergoing surgery for congenital heart disease, the  
132 vasoactive-ventilation-renal score obtained 12 hours after ICU arrival was a strong  
133 predictor of clinical outcome. This novel score could prove to be a powerful tool for  
134 bedside assessment of illness severity and prognosis, triage of ICU resources, and  
135 stratification of clinical research subjects.

181

**182 Introduction**

183 Scoring indices that can accurately reflect the severity of illness in critically-ill patients  
184 can be extremely valuable in contemporary medicine, providing guidance in patient care  
185 (e.g. triage, prognostication) and clinical research (e.g. stratification). The development  
186 of a disease severity index for children recovering from cardiac surgery however has  
187 been somewhat elusive, in large part due to the inherent heterogeneity of anatomy and  
188 pathophysiology within this patient population. To this end, the novel vasoactive-  
189 ventilation-renal (VVR) score has recently demonstrated promise [1,2]. Specifically, the  
190 VVR calculated at 48 hours postoperatively has been shown to be a robust predictor of  
191 short-term clinical outcomes and consistently outperformed the vasoactive inotrope  
192 score (VIS) and serum lactate, which have been used as more traditional measures of  
193 postoperative disease severity [3-8].

194

195 Our previous studies of the VVR have had notable limitations. These studies have been  
196 restricted to patients less than 18 years of age who have required cardiopulmonary  
197 bypass. Adults undergoing surgery for congenital heart disease and children undergoing  
198 cardiac surgery without cardiopulmonary bypass (e.g. systemic-to-pulmonary shunt,  
199 pulmonary artery banding, etc.) have been excluded. Additionally, these prior reports  
200 focused only on VVR measurements obtained at admission, peak and 48 hour  
201 measurements. Peak and 48-hour VVR measurements in particular were chosen for  
202 these initial studies because these measurements have been the focus of the majority of  
203 research on the VIS.[3-5] The clinical utility of measurements obtained at specific  
204 postoperative time points earlier in the postoperative course has not yet been  
205 determined. To address these gaps in what is known regarding the VVR, we sought to  
206 conduct a more inclusive prospective observational study examining the VVR score. We  
207 postulated that the VVR would continue to be more predictive of outcomes as compared

208 to the VIS and serum lactate in this broader population of patients recovering from  
209 surgery for congenital heart disease. We also sought to determine if the VVR obtained  
210 at distinct time points earlier in the postoperative period, which would have more  
211 practical clinical value, would be as predictive of postoperative outcomes as the VVR  
212 calculated at 48 hours.

213

## 214 **Patients and Methods**

### 215 *Patient Population*

216 This prospective observational validation study was approved by the Institutional Review  
217 Board within the Office of Research Compliance at Indiana University. Due to the  
218 observational nature of the study, consent was waived by the Institutional Review Board.  
219 All patients admitted to the cardiovascular intensive care unit (CVICU) at Riley Hospital  
220 for Children in Indianapolis, Indiana, from January 1, 2015 through June 30, 2015 were  
221 prospectively reviewed. Patients who required extracorporeal membrane oxygenation  
222 (ECMO) for the first 48 hours of CVICU admission were excluded, as their vasoactive  
223 medication regimens and ventilator requirements would not be reflective of their  
224 underlying disease severity but rather of the mechanical support provided by the  
225 extracorporeal circuit. All other patients were followed throughout their clinical courses  
226 and included in all analyses.

227

### 228 *Data Collection*

229 Pre- and perioperative data collected included: age, anthropometric measurements at  
230 time of surgery, anatomic diagnosis and procedure performed, Society of Thoracic  
231 Surgeons-European Association for Cardio-Thoracic Surgery Congenital Heart Surgery  
232 mortality category (STAT mortality category),[9] cardiopulmonary bypass duration, aortic  
233 cross-clamp duration, duration of hypothermic circulatory arrest if used, and preoperative

234 serum creatinine values. All arterial blood gas and lactate measurements (which are  
235 performed simultaneously using point-of-care testing) obtained during the first 48  
236 postoperative hours were recorded daily by study personnel, along with the ventilator  
237 support at the time of each measurement, which included respiratory rate (RR), fraction  
238 of inspired oxygen (FiO<sub>2</sub>), peak inspiratory pressure (PIP), positive end expiratory  
239 pressure (PEEP), and mean airway pressure (MAP). Patients at our institution are  
240 typically managed postoperatively with synchronized intermittent mandatory ventilation /  
241 pressure-regulated volume control, and typically extubated, at the discretion of the  
242 primary care team, from mechanical ventilator support when breathing comfortably with  
243 good gas exchange and without metabolic acidosis on the following ventilator settings:  
244 respiratory rate ≤ 10 breaths per minute, pressure support ≤ 10 cmH<sub>2</sub>O, positive end-  
245 expiratory pressure ≤ 5 cmH<sub>2</sub>O, and fraction of inspired oxygen concentration ≤ 0.4.  
246 Doses of inotropic and vasopressor medications (e.g. dopamine, dobutamine,  
247 epinephrine, norepinephrine, milrinone, and vasopressin) at the time of each arterial  
248 blood gas measurement were also recorded. Lastly, serum creatinine values obtained  
249 on admission, postoperative day 1 and postoperative day 2 were recorded.

250

#### 251 *Derivation of the Vasoactive Ventilation Renal Score*

252 Throughout each patient's hospital course, we calculated the patients' VIS at the time of  
253 each postoperative arterial blood gas measurement. The VIS was calculated in the  
254 following manner [3]:

255

256 VIS = dopamine dose (mcg/kg/min) + dobutamine dose (mcg/kg/min) + 100 \*  
257 epinephrine dose (mcg/kg/min) + 10 \* milrinone dose (mcg/kg/min) + 10,000 \*  
258 vasopressin dose (U/kg/min) + 100 \* norepinephrine dose (mcg/kg/min).

259

260 For patients on no vasoactive support at the time of blood gas measurement, VIS  
261 equaled zero. Secondly, the ventilation index (VI) was calculated for each postoperative  
262 arterial blood gas measurement as follows [10]:

263

$$264 \quad \text{VI} = (\text{Ventilator RR}) * (\text{PIP-PEEP}) * \text{PaCO}_2 / 1000$$

265

266 Use of the VI, which incorporates PaCO<sub>2</sub> rather than PaO<sub>2</sub> into its formula, permits the  
267 inclusion of patients with mixing lesions and single ventricle anatomy in the study, as  
268 PaCO<sub>2</sub> is less affected by intra-cardiac shunting. For patients not requiring mechanical  
269 ventilation at the time of arterial blood gas measurement, VI equaled zero. Lastly,  
270 baseline preoperative serum creatinine was subtracted from each postoperative serum  
271 creatinine measurement (e.g. on admission, and postoperative days 1 and 2), which we  
272 labeled ΔCr. For patients in which postoperative serum creatinine measurements were  
273 less than or equal to baseline, we recorded ΔCr = 0. Creatinine was measured in  
274 mg/dL. (For centers where creatinine is measured in mmol/L, we recommend converting  
275 to mg/dL to calculate the score as follows: serum creatinine (mmol/dL) x 0.0113 =  
276 serum creatinine (mg/dL)).

277

278 Using each of these individual measurements, we then calculated the VVR at the time of  
279 each arterial blood gas measurement as follows:

280

$$281 \quad \text{VVR} = \text{VIS} + \text{VI} + (\Delta\text{Cr} * 10)$$

282

283 VVR scores at 6, 12, 24, and 48 hours postoperatively were recorded.

284

285 *Statistical Analyses*

286 Descriptive statistics are provided as medians with interquartile ranges (IQR) for  
287 continuous variables and absolute counts with percentages for categorical variables.  
288 The primary outcome of interest was hospital length of stay (LOS). We opted to focus  
289 the study on hospital LOS because we deemed criteria for hospital discharge as  
290 compared to ICU discharge to likely be less inconsistent across centers. Hospital LOS  
291 is also inclusive of time spent in the ICU related to unplanned readmission after transfer  
292 to the cardiology ward. This outcome was dichotomized as upper (worst) 25<sup>th</sup> percentile  
293 versus lower 75<sup>th</sup> percentile. Patients in the upper 25% were defined as having  
294 prolonged LOS. Bivariate logistic regression analyses were performed to determine the  
295 individual contributions of VVR, VIS and serum lactate as predictors of LOS. This  
296 analysis was repeated for each of the four recorded time points. Receiver operative  
297 characteristic (ROC) curves were generated and the abilities of the predictors to  
298 correctly classify LOS were compared using area under the curve (AUC) values. AUC  
299 values for VVR at the study time points were compared using the method of DeLong,  
300 DeLong, and Clarke-Pearson as implemented by SAS.[11]

301

302 Bivariate comparisons were performed for demographic and surgical characteristics of  
303 patients with and without prolonged LOS using Wilcoxon rank-sum tests, X-square test,  
304 or Fisher's exact test as appropriate for individual variables. Variables that attained a  
305 bivariate significance of  $\leq 0.30$  and were of clinical relevance were considered for  
306 inclusion in a multivariable logistic regression model. Linearity in the logit was examined  
307 for continuous variables prior to model-building; those with evidence of non-linearity  
308 were converted to categorical variables. To obtain the best model, stepwise selection  
309 was used with a significance level of 0.3 for entry into the model, and 0.05 for staying.  
310 All statistical analyses were performed using STATA version 13 and SAS version 9.4.

311

## 312 **Results**

### 313 *Study Population*

314 During the study period, 168 unique patients were admitted to the cardiovascular ICU  
315 postoperatively. Four patients required ECMO support for the first 48 postoperative  
316 hours and were excluded from analysis. All other patients ( $N=164$ ) were included in the  
317 analysis, median age 9.3 months (range: 1 day - 33 years). A summary of the  
318 demographic and clinical characteristics of the patient cohort are shown in Table 1.  
319 Median hospital LOS, our primary outcome variable, was 8 days (IQR: 5-17.5).  
320 Prolonged LOS was therefore defined as greater than 17.5 days. Three patients died  
321 before hospital discharge, all of which had prolonged hospital LOS prior to their deaths  
322 (range 29 - 148 days). In addition, the hospital LOS for the four excluded patients who  
323 required ECMO support for the first 48 hours ranged from 38 to 248 days, and none of  
324 these patients died prior to hospital discharge.

325

326 Median serum lactate, VIS, and VVR measurements with IQR and maximum values are  
327 presented in Table 2 for all study time points. We obtained ROC curves via bivariate  
328 logistic regression analysis for 6, 12, 24, and 48-hour serum lactate, VIS, and VVR as  
329 predictors of prolonged LOS. The AUC values for these models are also provided in  
330 Table 2. Similar to our prior studies [1,2], VVR performed well and had a greater AUC  
331 than the corresponding VIS and serum lactate at each time point ( $P < 0.05$  for all  
332 comparisons). We also performed ROC analysis for age, weight, duration of  
333 cardiopulmonary bypass, and STAT category as predictors of prolonged LOS. The VVR  
334 at each of the four study time points was more predictive of prolonged LOS than any of  
335 these patient variables ( $P < 0.05$  for all comparisons). The ROC curves for prolonged  
336 LOS and serum lactate, VIS, and VVR at 12 hours postoperatively, as well as STAT  
337 mortality category, are illustrated in Figure 2.

338

339 The AUCs for the VVR at 6, 12, 24, and 48 hours are statistically compared to each  
340 other in Supplemental Table 2. There were no statistical differences between the ROC  
341 curves for any of the VVR time points. In other words, the VVR at 6, 12, and 24 hours  
342 were, at the very least, as predictive as the VVR at 48 hours. Of the four VVR  
343 measurements, the 12-hour VVR had the highest AUC, 0.93 (95% CIs: 0.89-0.97). For  
344 this reason, the remainder of the analysis is focused on this time point.

345

346 Demographic and clinical variables for patients with and without prolonged hospital LOS  
347 are compared in Table 3. All variables with  $P$ -value  $<0.3$  were considered for the  
348 multivariable model. On multivariable regression analysis, the 12-hour VVR remained a  
349 strong independent predictor of prolonged LOS. Specifically, with each increase of 1 in  
350 a patient's 12-hour VVR score, the odds of a prolonged LOS increased by 15% (OR:  
351 1.15, 95% CI: 1.10, 1.20). Other variables that were independently associated with  
352 prolonged LOS were the presence of non-cardiac anatomic abnormalities and the use of  
353 inhaled nitric oxide. The remaining variables that were significant on bivariate analysis,  
354 namely age, weight, STAT category 4 or 5, duration of cardiopulmonary bypass, and  
355 admission lactate, were not significant on multivariable analysis and did not appreciably  
356 affect the model. Delayed sternal closure and the need for CPR were not included in the  
357 multivariable analysis because of the small number of patients within the study who had  
358 these postoperative complications. The best multivariable model for prolonged LOS  
359 including the 12-hour VVR, inhaled nitric oxide use, and non-cardiac anatomic  
360 abnormalities is presented in Table 4. The AUC for the model was 0.94 (95% CI: 0.91,  
361 0.98). ROC curves for the model and its individual components are shown in Figure 2.

362

363 To simplify the interpretation and use of the 12-hour VVR, we dichotomized the variable  
364 into high and low. A 12-hour VVR cutoff value of 25 was chosen to maximize total  
365 accuracy and minimize weighted error ratios, and this cutoff correctly classified 90% of  
366 patients. Patients with 12-hour VVR greater than or equal to 25 were therefore defined  
367 as having a high VVR score. On multivariable logistic regression analysis, after  
368 adjustment for the presence of inhaled nitric oxide and non-cardiac anatomic  
369 abnormalities, high VVR at 12 hours remained strongly associated with prolonged LOS  
370 (odds ratio: 31; 95% CI: 10 - 90).

371

372 **Comment**

373 We have further validated the VVR as a multi-organ system severity of illness index for  
374 patients recovering from surgery for congenital heart disease. We have now  
375 demonstrated that the VVR strongly predicts hospital length of stay, more so than the  
376 VIS and serum lactate, in a patient population that not only includes children requiring  
377 cardiopulmonary bypass but also includes children undergoing procedures without  
378 cardiopulmonary bypass and adults with congenital heart disease. The patients included  
379 in this study reflect the postoperative patient populations at many centers, where adults  
380 undergoing surgery for congenital heart disease are commonly cared for within pediatric  
381 cardiovascular ICU's [12,13]. The greater heterogeneity of the patient population in this  
382 study has increased the strength and practicality of the VVR.

383

384 In our prior work, the VVR calculated at 48 hours was superior to admission and peak  
385 VVR measurements.[1,2] In fact, admission measurements performed poorly. This  
386 finding was not surprising, as vasoactive and ventilator support upon CVICU admission  
387 are likely less reflective of organ dysfunction and illness severity but rather more related  
388 to the dynamic processes that occur after cessation of cardiopulmonary bypass and

389 during transport to the CVICU. Likewise, the support upon admission may also be the  
390 peak support, which will negatively affect the strength of peak VVR measurements. We  
391 have now demonstrated that the VVR calculated at specific time points earlier in than 48  
392 hours postoperatively can also reliably predict clinical outcome in children recovering  
393 from cardiac surgery. Specifically, patients with a VVR score greater than or equal to 25  
394 at the 12 hours postoperatively were 31 times more likely to have a prolonged length of  
395 stay as compared to patients with lower VVR scores. This ability to provide important  
396 prognostic data earlier in the postoperative course further increases the functionality of  
397 the VVR.

398

399 The advantages of the VVR as compared to the VIS and serum lactate, as we have  
400 discussed in our prior work [1,2], should be intuitive to physicians caring for these  
401 children, as the VVR likely captures that subset of patients who have may have  
402 preserved hemodynamic integrity yet have significant burden of disease from  
403 postoperative lung or kidney injury. The additional components of the VVR, though on  
404 the surface may seem cumbersome to some, can be obtained from routinely available  
405 bedside data and the score can be quantitated with a simple calculator. Incorporation of  
406 VVR calculation into the electronic medical record could further enhance its utility. If  
407 available to physicians at the bedside, the 12-hour VVR has several potential clinical  
408 applications. The 12-hour VVR could provide a reliable estimate of illness severity, give  
409 parents and families realistic expectations of their child's postoperative course, or  
410 potentially assist with triage CVICU resources. Additionally, the 12-hour VVR could  
411 help stratify potential research subjects or assist with propensity score matching.  
412 Further validation in a multi-center data set should, however, be performed before  
413 widespread application is recommended.

414

415 This study also found that the use of inhaled nitric oxide and the presence of non-cardiac  
416 anatomic abnormalities had an effect on hospital LOS that was independent of the organ  
417 dysfunction quantitated by the 12-hour VVR. Use of inhaled nitric oxide, in many cases,  
418 represents an escalation of cardiopulmonary support beyond traditional vasoactive  
419 medications and ventilatory support. It is therefore somewhat intuitive that its use is  
420 associated with prolonged LOS, independent of the VVR. Likewise, the presence of  
421 non-cardiac anatomic abnormalities such as airway anomalies or gastrointestinal defects  
422 (e.g. intestinal malrotation, imperforate anus, Hirschsprung's disease) would not be  
423 accounted for by the VVR yet could surely prolong LOS, especially if surgical  
424 interventions were needed to address those abnormalities. Though the VVR at 12 hours  
425 in and of itself was a solid predictor of prolonged LOS, addition of these important  
426 variables further elevated the strength of our predictive model (Figure 2).

427

428 There are some limitations that must be noted. These data come from a single center,  
429 which limits their generalizability. The initial work on the VVR was however completed at  
430 a different center [1,2] and thus the VVR has now been validated as a predictor of  
431 postoperative outcome at two different institutions with different cardiac surgeons and  
432 varying practices. A multi-center validation study is the next step. Larger studies should  
433 also determine if the VVR has the ability to predict additional outcomes (most important  
434 of which is postoperative mortality), and whether other variables such as delayed sternal  
435 closure or the need for CPR have an effect on outcome independent of the VVR. We  
436 acknowledge that the VVR cannot reliably be calculated for patients requiring ECMO  
437 support, though the need for ECMO in these patients, in and of itself, is considered by  
438 most clinicians to be a reliable marker of disease severity. Indeed, all four patients who  
439 were excluded due to ECMO support would be characterized as having prolonged LOS.  
440 Also, no patients in our cohort required peritoneal dialysis or continuous renal

441 replacement therapy within the first 48 hours postoperatively, but either modalities could  
442 also affect the reliability of the score. Finally, the VVR remains affected by limitations  
443 previously noted in the VIS [3] - it does not assess the importance of the individual  
444 components of the VIS, and vasoactive medication administration as well as the degree  
445 of mechanical ventilator support were not under protocol and so may have been affected  
446 by variation in physician practice.

447

#### 448 **Conclusions**

449 We have further validated the utility of the VVR score after surgery for congenital heart  
450 disease. The VVR calculated at 12 hours postoperatively could be a valuable and  
451 potentially powerful clinical tool to predict important postoperative outcomes in this  
452 patient population.

**Tables**

Table 1: Patient Demographic Characteristics

Characteristic	All Patients (n=164)
Age (months)	9.3 (2.6 – 57.8)
Male (n)	102 (62%)
Weight (kg)	7.8 (4.6 – 17.8)
Race (n)	
Caucasian	131 (80%)
African American	23 (14%)
Asian	7 (4%)
Other	3 (2%)
Genetic / chromosomal abnormalities (n)	35 (21%)
Trisomy 21	17 (10%)
Other	18 (11%)
Non-cardiac anatomic abnormalities (n)	30 (18%)
STAT category (n)	
1	52 (32%)
2	41 (25%)
3	31 (19%)
4	31 (19%)
5	7 (4%)
Other	2 (1%)
Preoperative creatinine (mg/dL)	0.35 (0.29 - 0.50)
Cardiopulmonary bypass duration (min)	88 (59 -136)
Aortic cross clamp duration (min)	42 (15 – 66)
Delayed sternal closure (n)	16 (10%)
Postoperative inhaled nitric oxide use (n)	27 (16%)
Admission lactate (mg/dL)	2.0 (1.3 - 2.9)
Postoperative CPR (n)	6 (4%)

CPR: cardiopulmonary resuscitation; STAT: Society of Thoracic Surgeons-European Association for Cardio-Thoracic Surgery Congenital Heart Surgery mortality category

Data represented as absolute counts (%) or median (interquartile range)

Table 2: Relationship between postoperative measurements and prolonged LOS

Postoperative Variables	Median (IQR)	Maximum	AUC (95% CI)
6-hours:			
Lactate (mg/dL)	1.3 (0.8 - 2.6)	9.2	0.75 (0.67 - 0.84)
VIS	0 (0 - 5)	15.5	0.81 (0.74 - 0.88)
VVR	5.2 (0.6 - 24.3)	96	0.93 (0.89 - 0.97)
12-hours:			
Lactate (mg/dL)	1.1 (0.7 - 1.9)	9.7	0.78 (0.71 - 0.86)
VIS	0 (0 - 5)	16	0.81 (0.73 - 0.88)
VVR <sup>a</sup>	3.5 (0.2 - 24.6)	75	0.93 (0.89 - 0.97)
24-hours:			
Lactate (mg/dL)	0.9 (0.7 - 1.4)	5.4	0.61 (0.52 - 0.71)
VIS	0 (0 - 5)	17	0.84 (0.77 - 0.91)
VVR	1.7 (0 - 20.9)	64	0.91 (0.84 - 0.97)
48-hours:			
Lactate (mg/dL)	0.85 (0.6 - 1.3)	5.4	0.55 (0.45 - 0.65)
VIS	0 (0 - 4.5)	17.5	0.83 (0.76 - 0.91)
VVR	0.5 (0-11.1)	64	0.89 (0.81 - 0.96)
Age (months)	9.3 (2.6 - 57.8)	33 years	0.78 (0.70 - 0.87)
Weight (kg)	7.8 (4.6 -17.8)	100	0.80 (0.72 - 0.88)
STAT category	2 (1 - 3)	5	0.79 (0.72 - 0.87)
CPB duration (min)	87.5 (59 -136)	345	0.66 (0.55 - 0.77)

<sup>a</sup> AUC for VVR at 12 hours was 0.933, slightly greater than AUC for VVR at 6 hours of 0.929

AUC: Area under the receiver operating characteristic curve; CPB: cardiopulmonary bypass; CI: confidence interval; IQR: interquartile range; LOS: hospital length of stay; STAT: Society of Thoracic Surgeons-European Association for Cardio-Thoracic Surgery Congenital Heart Surgery mortality category; VIS: vasoactive inotrope score; VVR: vasoactive-ventilation-renal score

Table 3. Bivariate Analysis Comparing Patients With and Without Prolonged LOS

Characteristic	Prolonged LOS (n=41)	No Prolonged LOS (n=123)	P-value
Age (months)	1.5 (0.3 - 6.5)	11.5 (6.3 - 80)	<0.001
Male (n)	28 (68%)	74 (60%)	0.35
Weight (kg)	4.2 (3.4 - 5.5)	8.5 (6.1 - 22.3)	< 0.001
Genetic abnormalities (n)	7 (17%)	28 (23%)	0.44
NCAA (n)	13 (32%)	17 (14%)	0.01
STAT category 4 or 5 (n)	21 (51%)	17 (14%)	<0.001
Preoperative creatinine (mg/dL)	0.35 (0.29 - 0.48)	0.35 (0.29 - 0.51)	0.42
CPB Duration (min)	129 (78 - 173)	82 (56 - 122)	0.002
Aortic cross clamp duration (min)	53 (22 - 70)	36 (14 - 60)	0.13
Delayed sternal closure (n)	15 (37%)	1 (1%)	<0.001
Postoperative iNO use (n)	19 (46%)	8 (7%)	<0.001
Admission lactate (mg/dL)	2.3 (1.7 - 5)	1.9 (1.3 - 2.7)	0.004
VVR at 12 hours	31 (27 - 40)	1 (0 - 11)	<0.001

*CPB*: Cardiopulmonary bypass; *iNO*: inhaled nitric oxide; *NCAA*: non-cardiac anatomic abnormalities; *STAT*: Society of Thoracic Surgeons-European Association for Cardio-Thoracic Surgery Congenital Heart Surgery mortality category; *VVR*: vasoactive-ventilation-renal score  
 Data represented as absolute counts (%) or median (interquartile range)

Table 4. Multivariable Regression Analysis for Predictors of Prolonged LOS

Parameter	Estimate	SE	P-value	Odds Ratio (95% CI)
Intercept	-4.20	0.64	<0.0001	-
12-hour VVR	0.14	0.02	<0.0001	1.15 (1.10, 1.20)
Inhaled nitric oxide	1.50	0.71	0.033	4.50 (1.13, 17.99)
Non-cardiac anatomic abnormalities	1.54	0.73	0.034	4.67 (1.13, 19.34)

CI: Confidence interval; LOS: length of stay; SE: standard error; VVR: vasoactive-ventilation-renal score

**Supplemental Table 1.** Cardiovascular Surgical Procedures Organized by STAT Mortality Categories

Primary surgical procedure	All Patients (N=164)
<b>STAT Category 1</b>	<b>52 (32%)</b>
Repair, atrial septal defect	9
Repair, ventricular septal defect	13
Repair, Tetralogy of Fallot	9
Pulmonary valve replacement	7
Lateral tunnel Fontan operation	4
Repair, partial atrioventricular canal defect	3
Other	7
<b>STAT Category 2</b>	<b>41 (25%)</b>
Repair, coarctation of the aorta	8
Aortic valvuloplasty	6
Repair, Tetralogy of Fallot	4
Extracardiac Fontan operation	3
Bidirectional Glenn operation	3
Other	17
<b>STAT Category 3</b>	<b>31 (18%)</b>
Arterial Switch procedure (d-TGA w/IVS)	5
Hemi-Fontan operation	6
AV-Canal	5
Repair, pulmonary atresia w/VSD	5
Right ventricle-to-pulmonary artery conduit	4
Other	6
<b>STAT Category 4</b>	<b>31 (19%)</b>
Systemic-to-pulmonary artery shunt	7
Orthotopic heart transplant	5
Repair, total anomalous pulmonary venous return	5
Arterial switch procedure (d-TGA w/VSD)	2
Pulmonary artery banding	3
Other	9
<b>STAT Category 5</b>	<b>7 (4%)</b>
Norwood operation	6
Damus-Kaye Stanzel operation	1

d-TGA: d-transposition of the great arteries; IVS: intact ventricular septum; VSD: ventricular septal defect

**Supplemental Table 2.** Statistical Comparison for Area under the Curve Values for the Vasoactive-Ventilation-Renal (VVR) score and Prolonged Length of Stay at 6, 12, 24, and 48 hours.

Contrast	Estimate	SE	95% Wald CL		Chi-Square	P-value
