Introduction: Gemcitabine (GEM)-platinum chemotherapy is validated first-line strategy for patients with recurrent/advanced cholangiocarcinoma (CK), with

progression-free survival (PFS) of 6-8 months. No standard second-line chemotherapy after GEM-platinum failure exists and data on survival benefit remain limited.

Methods: We retrospectively reviewed patients with recurrent/advanced CK who received the GEM-oxaliplatin combination (GEMOX) followed by 5-fluorouracil combined with irinotecan (FOLFIRI) to evaluate the efficacy of the sequential treatment strategy. Overall survival (OS) and PFS were calculated by Kaplan-Meier method.

Results: Fifty-two patients were analyzed, 21 (40%) had intrahepatic CK, 14 (27%) had hilar/extrahepatic CK, and 17 (33%) had gallbladder cancer. Median age was 64 years (range: 38-79 year). Prior to GEMOX, 49 (94%) and 3 (6%) patients were performance status (PS) 0-1 and PS 2, respectively; and before FOLFIRI, 14 (27%) patients were PS 2-3. Prior curative-intent resection of the primary tumor was performed in 23 (44.2%) patients and 12 (23.1%) patients received GEMOX adjuvant chemotherapy. After a median follow-up of 36.3 months, 47 (90.4%) patients completed the treatment strategy. First-sequence GEMOX and second-sequence FOLFIRI achieved 4.8 months and 3.2 months median PFS, respectively. The global OS for the sequential chemotherapy was 21.9 months. The sequence of FOLFIRI resulted in a median OS of 8.4 months.

Conclusion: The sequence of GEMOX-FOLFIRI is a potential treatment strategy for patients with recurrent/advanced CK. However, only a modest impact on OS was observed. Further studies with novel therapeutic agents to improve survival in CK patients are required.
