1. INTRODUCTION

Genetic logic circuits are becoming popular as an emerging field of technology. They are composed of genetic parts of DNA and work inside a living cell to perform a dedicated boolean function triggered by the presence or absence of certain proteins or other species.

In this work, we introduce a top-down approach to synthesize genetic logic circuit. This approach is based on translating high-level description of genetic circuit (in the form of boolean function) to its low-level representation in the form of SBOL [1] notation. This approach is implemented in the *Genetic Technology* mapping tool, *GeneTech*. It takes the Boolean expression of a genetic circuit as input, and then first optimize it. It then synthesizes the optimized Boolean expression into NOR-NOT form in order to construct the circuit using the real NOR/NOT gates available in the genetic gates library [2]. In the end, *GeneTech* performs technology mapping to generate all the feasible circuits, with different genetic gates, to achieve the desired logical behavior.

There are some existing tools which supports technology mapping of genetic circuits including Cello [2] and iBioSim [3]. *GeneTech* differs from these tools by generating all feasible genetic circuits from a Boolean expression. This work is originally inspired from the processes of optimization and technology mapping of electronic circuits in the *electronic design automation* (EDA) industry. In EDA, the combinatorial circuit optimization is always required to implement the circuit with the minimum number of logic gates [4]. This area-efficient implementation of digital circuits not only helps reducing the size of electronic devices but also avoid wasting power and redundant resources.

Figure 1. Digital circuit of the expression $ab + b + ac$.
 (a) Original circuit. (b) Optimized circuit having two gates.

In order to get the insight of logic optimization, consider the digital circuit for the Boolean expression, $ab + b + ac$, shown in Figure 1(a). In this figure, the circuit consists of four logic gates. After running the optimization algorithm, the number of gates in the circuit reduces down to two while preserving the original functionality, as illustrated in Figure 1(b).

This optimization of digital electronic circuits seems simple and straight forward. However, the optimization and technology mapping of genetic circuits is not similar to electronic circuits. This is because the input and output quantities of electronic circuits are the same i.e. voltage, and therefore the electronic gates can easily be cascaded together. On the contrary, the input and output quantities of genetic gates are different, and therefore the

signal matching has to be considered while mapping genetic gates on the circuit. This makes it very challenging to integrate genetic logic gates to construct complex genetic circuits. Similar to the above process of optimizing digital logic in electronic circuits, we want to avoid having redundant logic in genetic circuits as well.

2. METHODOLOGY

Two different ways to represent the same boolean logic or digital circuit are the *minterm* and *maxterm* canonical forms. Minterms are also called the *products* because the variables (or literals) in the Boolean expressions are represented as the *logical AND*. Maxterms are referred to as *sums* because the variables (or literals) are represented as the *logical OR*. Therefore, the same Boolean function can either be expressed as the *sum of products/minterms* (SOP) or the *product of sums/maxterms* (POS), as shown in equation (1). In this example, the left-hand side represents the SOP form and the right-hand side represents its equivalent POS form.

$$ab + b + ac = (a + b + c)(a + b + \bar{c})(\bar{a} + b + c) \quad (1)$$

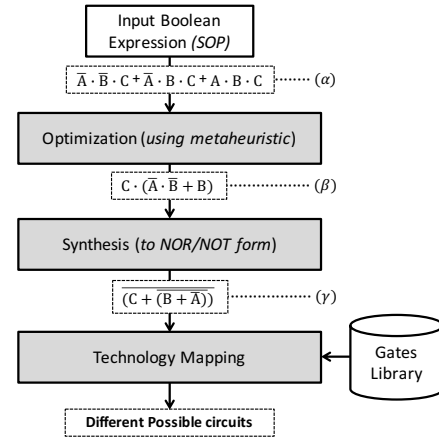

Figure 2. The technology mapping flow of *GeneTech*.

The flow of genetic technology mapping in *GeneTech* is shown in Figure 2. It takes the raw Boolean expression in the SOP form and then first optimize it using the *simulated annealing* (SA) [5] optimization algorithm. The goal of optimization at this step is to reduce the number of variables (or literals) in the expression while keeping the output logic the same. Reducing the number of literals in the Boolean expression results in the reduction of logic components required to obtain the desired logic.

To construct real genetic circuits, *GeneTech* uses the gates library from [2], which consists of genetic gates in the form of NOR and NOT functions. Therefore, to map the genetic gates on the Boolean expression, it is necessary to bring it into NOR/NOT form. Hence, when the Boolean expression is optimized, it then goes to a process of synthesis, as shown in Figure 2. Once the Boolean expression is available in NOR/NOT form, a mapping
