Hostile attributions bias and perceived self-efficacy of adolescent bullies, victims, bully-victims, and those uninvolved in bullying.

Simon C. Hunter, James M.E. Boyle & David Warden University of Strathclyde

BPS Scottish Branch Conference 2004 Fisher's Hotel, Pitlochry, 26-28 November

simon.hunter@strath.ac.uk

Background

- Clarification of the cognitive underpinnings of involvement in bullying should improve intervention and prevention work
- Self-efficacy?
 - → distinguish between efficacy for aggressive and non-aggressive behaviours?
- Hostile attributions biases?
 - → Regardless of hostile attribution bias, selfefficacy (as above) predicts use of aggression or prosocial behaviour
 - → However, hostile attribution biases may differentiate between bullies and bully-victims

Background

 Theoretical basis for differentiating intervention and/or prevention based on theory?

Hypotheses

- Victims will have lower overall self-efficacy (i.e. for both aggressive and non-aggressive actions) compared to uninvolved pupils
- 2. Bully-victims and bullies will have higher aggressive self-efficacy than victims and uninvolved pupils
- 3. Bully-victims will have a higher hostile attribution bias than victims, bullies and uninvolved pupils

Method

- Participants were 520 pupils (49% male) aged 12 -14 years attending mainstream Scottish schools.
 Three hundred and six pupils were in Secondary Two and 205 in Secondary Three.
- Measures were completed in classroom settings:
 - → victimisation
 - → self-efficacy vignette measure
- → hostile attribution bias vignette measure (latter two measures based on Hubbard et al.'s 2001 measures)

Results

- Bullies: 5% overall (7% of boys, 4% of girls)
- Bully-victims: 9% overall (9% of boys, 8% of girls)
- Victims: 35% overall (33% of boys, 36% of girls)
- Uninvolved: 51% overall (50% of boys, 52% of girls)
- Aggressive and non-aggressive self-efficacy scores correlated (r = .44, p < 0.001)
- Neither type of self-efficacy correlated with hostile attribution score
- 3-way mixed-ANOVA: gender x bullying involvement (bully/ bully-victim/ victim/ uninvolved) x selfefficacy (aggressive/ non-aggressive)

Results

Self-efficacy:

- 3-way mixed-ANOVA: gender x bullying involvement (bully/ bully-victim/ victim/ uninvolved) x selfefficacy (aggressive/ non-aggressive):
 - → no effect of gender.
 - → main effect of self-efficacy: overall, pupils reported significantly higher non-aggressive than aggressive self-efficacy.
 - → main effect of bullying involvement: victims reported significantly lower overall self-efficacy than uninvolved pupils.
 - → no interactions.

Results

Hostile Attribution Bias:

- 2-way ANOVA: gender x bullying involvement (bully/bully-victim/ victim/ uninvolved)
 - → no main effects or interactions.

Discussion

- Victims reported significantly lower self-efficacy than uninvolved pupils (and were lower than all other groups at a trend level)
 - → such perceptions are likely to contribute toward the maintenance of victimisation by encouraging less adaptive responses i.e. submissive and unassertive behaviours
- Hostile attribution biases unrelated to status

 → perhaps bully victims are not simply
 provocative victims, and these two groups must
 be distinguished more clearly
