Diversity oriented synthesis of fused pyrimidines leads to scaffolds with many biological activities. In the case of the preparation of pyrido[2,3-d]pyrimidines from 2alkylthiopyrimidines, the formation of a new carbon-carbon bond at C 5 is required, a reaction that is very limited in scope. However Claisen type rearrangement of simple 4-allylic ethers affords C5 substituted pyrimidines readily; in cases with an ester substituent, rearrangement occurs at room temperature. Subsequent cyclisation to afford 6-methylpyrido[2,3$d]$ pyrimidin- $7(8 H)$-ones was achieved in high yield. Using allylic ethers derived from 3-chloromethyl-4-arylbut-3-en-2-ones as substrates, a new titanium[IV]chloride catalysed reaction affording 6 -arylmethyl-7-methylpyrido $[2,3-d]$ pyrimidines was discovered. In contrast, 2-alkylthiopteridines are readily available. In both cases, substitution at C 2 and C 4 to generate diversity has been carried out and the reactivity compared; yields of substitution products were generally higher with pteridine substrates. In biological assays unexpected hits were found for activity against the Gram positive bacterium, Nocardia farcinia, and against the parasite Trypanosoma brucei brucei, illustrating the value of diversity oriented synthesis in the discovery of biologically active compounds.

## 1. Introduction

Whilst the synthesis of pteridines and related bicyclic nitrogen heterocycles is established, ${ }^{1}$ the synthesis of their deaza analogues requires further development because most methods for the synthesis of such compounds have not been designed with the intention of creating highly diverse libraries of compounds as is required for modern medicinal chemistry in which multiple biological targets may be relevant. With emphasis on diversity oriented synthesis in our own studies, we have identified active compounds with respect to GTP cyclohydrolase $1,{ }^{2}$ dihydropterin diphosphokinase, ${ }^{3}$ dihydrofolate reductase, ${ }^{4}$ pteridine reductase $1^{5}$ and nitric oxide synthase. ${ }^{6}$ Several of these targets are significant clinically and the optimisation of activity requires the availability of more diverse libraries within the same basic structural skeleton. Our recent work, therefore, has emphasised maximising the number of easily variable sites, so that at least three variations are readily available from one synthetic stream. At the centre of these developments has been the alkylthio substituent, either at C 2 or C 4 of a pyrimidine and we have established a prototype solid phase synthesis of pteridines using this linker which proceeds through C5 nitrosation of the alkylthiopyrimidine. ${ }^{7}$ Extension of this chemistry to pyrido $[2,3-d]$ pyrimidines and pyrrolo $[2,3-d]$ pyrimidines requires carbon substitution to take place at C5 of the pyrimidine. Although a 2- or 4-alkylthio substituent gives access to diversity, via oxidation and nucleophilic displacement, the presence of the alkylthio substituent significantly reduces the reactivity of C5 to electrophiles compared with the more common 2-amino substituent such that carbon electrophiles, do not react. A significant exception is that when certain Michael acceptors are used, C5 substitution occurs in reduced yield ${ }^{8}$ and this chemistry has been developed to provide compounds with significant activity against Trypanosoma brucei. ${ }^{5}$ A further example of a successful C5 substitution of a 2-alkylthiopyrimidine is found in nucleoside analogue synthesis and involves Vilsmeier formylation. ${ }^{9}$ In contrast, halogen electrophiles substitute 2-alkylthiopyrimidines in high yield and provide suitable precursors for C 5 carbon substitution. ${ }^{10}$ In view of the low reactivity of these intermolecular substitution reactions, we hypothesised that intramolecular C5 substitution might be successful and that suitable precursours for the Claisen allyl rearrangement would be available from O 4 allyl ethers. Allyl rearrangements have been used in the synthesis of many natural products. ${ }^{11}$ The Claisen rearrangement was first described in the pyrimidine series in 1961 but the reactions lacked functional groups for further transformations leading to fused pyrimidines. ${ }^{12}$

## 2. Results and discussion

### 2.1 Claisen rearrangement

To investigate further the Claisen rearrangement approach, ${ }^{12}$ pyrimidine $\mathbf{1}$ was treated with allyl bromide in DMF in the presence of solid potassium carbonate to afford a mixture of the O 4 and N 3 allyl pyrimidines 2 ( $62 \%$ ) and 3 ( $9 \%$ ), which were separable by column chromatography. The O 4 allylated pyrimidine 2 underwent quantitative Claisen rearrangement to afford 4 at $200{ }^{\circ} \mathrm{C}$ in the melt (Scheme 1); in previous work, reactions took place in high boiling solvents and gave only $20 \%$ yield.

Scheme 1. Substitution by Claisen rearrangement. Reagents and conditions: i. $\mathrm{DMF}, \mathrm{K}_{2} \mathrm{CO}_{3}$, $100^{\circ} \mathrm{C}, 20 \mathrm{~h}$; ii. $200^{\circ} \mathrm{C}, 24 \mathrm{~h}$

Cyclisation of 4 to either a pyrido[2,3-d]- or a pyrrolo[2,3-d]-pyrimidine proved unsuccessful using palladium catalysis. ${ }^{10}$ However, this cyclisation reaction was not a priority because the products of cyclisation of 4 would lack substituents in the newly formed ring, an outcome inappropriate for a diversity oriented synthesis; substituted allylic groups are necessary for library synthesis. In electrocyclic reactions, it is often found that the introduction of an electron withdrawing group to an alkene greatly increases the reaction rate. ${ }^{11}$ By using ethyl bromomethylacrylate as the alkylating agent and pyrimidine 1, two surprising results were obtained. Firstly, alkylation of the anion of $\mathbf{1}$ with ethyl bromomethylacrylate led directly to the disubstituted pyrimidine, $\mathbf{5}$ (Scheme 2); such a product could arise if rearrangement was exceptionally rapid and was followed by a subsequent $O$-alkylation. The structure of 5 was confirmed by X-ray crystallography. ${ }^{13}$

Scheme 2. Preparation of dialkylated pyrimidine 5 Reagents and conditions: i. DMF, $\mathrm{K}_{2} \mathrm{CO}_{3}, 55^{\circ} \mathrm{C}, 24 \mathrm{~h}$

This reaction suggested that both allyl ether formation and rearrangement surprisingly had taken place at room temperature. Pyrimidine 1 was therefore treated slowly over a period of days with ethyl bromomethylacrylate at room temperature in the absence of added base to afford the rearranged C5 alkylated product 6a (46\%). Similar reactions occurred between 1 and bromomethylacrylic acid to give $\mathbf{6 b}$ ( $30 \%$ ), as well as on the 2 -aminopyrimidine 7 a to give $\mathbf{6 c}$ and $\mathbf{6 d}$ in 83 and $53 \%$ yield respectively (Scheme 3). A set of 6-N-alkylpyrimidines (7b, 7c, 7d) was also prepared in a similar manner. As planned, the C 5 alkylated products were cyclised with nonnucleophilic base to afford a set of pyrido[2,3-d]pyrimidine-7( $8 H$ )-ones ( $\mathbf{6 f}-\mathbf{6 g}$ ). Optimisation of the cyclisation conditions of the C5 alkylated Claisen rearrangement products 6 showed that triazabicyclodecane (TBD) was more effective than diazabicycloundecane (DBU) and yields of $>80 \%$ were reproducibly obtained leading to a series of 2-alkylthiopyrido[2,3- $d]-3(4 H), 7(8 H)$-diones (Scheme 3) from which a library of compounds through C2 substitution was generated ( $\mathbf{8 a}-\mathbf{8 e}$ ).

### 2.2 Lewis acid catalysed rearrangement and cyclisation

In principle, the bromomethylacrylate substitution and Claisen rearrangement leads to pyrido $[2,3-d]$ pyrimidindiones with diversity at two positions and efforts were made to extend the reaction using more highly substituted acrylates without success. However the Claisen rearrangement route has further potential for the synthesis of diverse pyrido[2,3$d$ ]pyrimidines if ketones are used in place of esters. $\beta$-Halomethyl arylidene ketones are readily available through the Baylis-Hillman reaction using methyl vinyl ketone and the appropriately substituted aldehyde. ${ }^{14}$ Such compounds $\mathbf{9 a}, \mathbf{9 b}$ were found to react readily with the benzylthiopyrimidinone 1 in the presence of cesium carbonate to afford the $O$ alkyl products 10a, 10b in $60-70 \%$ yield. Unlike the previous examples, these compounds are stable at room temperature and do not rearrange cleanly on thermolysis. Base catalysis via an N6 anion formed using sodium hydride or DBU did not promote any reaction. Many metal complexes have been used to accelerate electrocyclic reactions including the Claisen rearrangement. ${ }^{11,15}$ Several Lewis acids were tested for their ability to promote rearrangement of the arylallyl ethers, 10; boron trifluoride, magnesium dibromide, stannic chloride, and zinc chloride failed but titanium tetrachloride (10 $\mathrm{mol})^{16,17}$ induced both a rearrangement and concomitant cyclisation to afford the 6-
arylmethylpyrido $[2,3-d$ ]pyrimidines 11a, 11b in modest yield (Scheme 4). It is notable that these are not the expected products of Claisen rearrangement and subsequent cyclisation, which would be 5 -aryl-6,7-dimethylpyrido[2,3-d]pyrimidines. Titanium tetrachloride catalysis has therefore caused the reaction to follow another course; the proposed mechanism for the reaction is shown in Scheme 5.

Scheme 4. Reagents and conditions: i. $\mathrm{Cs}_{2} \mathrm{CO}_{3}$, KI, r.t., 24 h ; ii. $\mathrm{TiCl}_{4} .2 \mathrm{THF}$, THF, reflux, 3 d

Scheme 5. Proposed mechanism for the synthesis of derivatives 11. Ti was introduced as $\mathrm{TiCl}_{4}$.2THF in THF solution.

Increasing the molar proportion of titanium tetrachloride up to $50 \mathrm{~mol} . \%$ also failed to improve yields. Indeed the major product under conditions of higher concentration of titanium tetrachloride was the precursor Baylis-Hillman chloroketone, 9. The occurrence of these competing reactions can be rationalised by a mechanism in which titanium tetrachloride generates an electrophile from the allyl ether, possibly with coordination also of the ketone carbonyl group to maintain an essentially intramolecular reaction. The initial coordination of titanium tetrachloride to the pyrimidyl ether would liberate chloride which, at the higher concentrations, traps the intermediate delocalised allylic cation 12 reverting to the starting material 9 . Nevertheless, two new pyrido[2,3$d]$ pyrimidines 11 were obtained for investigation of the introduction of diversity by modifications at C 2 and C 4 .

### 2.3 Diversification

Having established ring syntheses of pyrido[2,3-d]pyrimidines $\mathbf{1 1}$ from allyl ethers it was necessary to demonstrate diversification of these compounds at the 2-position. Two reactions were investigated, firstly oxidation of benzylthio substituents followed by nucleophilic substitution and secondly conversion of a 4-oxo substituent into a 4 aminoalkyl substitutent using BOP (benzotriazole-1-yl-
oxytris(dimethylamino)phosphonium hexafluorophosphate) and the corresponding amine. ${ }^{18}$ The oxidation/substitution sequence is successful and in high yield (typically 85 $-95 \%$ ) with pteridines and other compounds with electron deficient rings fused to pyrimidines. ${ }^{19-21}$ In many cases with pteridines as substrates, oxidation was not required before nucleophilic substitution of the alkylthio group. In this study, the range of examples has been extended to 4 -aminoalkyl pteridines as substrates, the latter being available through BOP chemistry as noted above. ${ }^{18}$

At the other extreme of reactivity, pyrrolo[2,3-d]pyrimidines underwent substitution only after oxidation, under vigorous conditions and in much lower yields. ${ }^{5}$ It would be reasonable to expect that the reactivity of pyrido[2,3- $d$ ] pyrimidines to nucleophilic substitution after oxidation would lie between these two extremes and this indeed proved to be the case. The 7-oxopyrido[2,3-d]pyrimidines $\mathbf{8 d}$ and $\mathbf{8 e}$ gave 13a-13d in yields typically of $50-60 \%$, somewhat greater than those for the pyrido[2,3-d]pyrimidines $\mathbf{1 1 b}$ lacking the 7 -oxo group, which afforded typically $35-55 \%$ yields of $\mathbf{1 4 a}-\mathbf{1 4 d}$ under the same conditions.

A further reaction of value in the diversification of oxo-heterocycles has been demonstrated by scientists from Wyeth who showed that oxo substituents in 4- and 7positions especially could be converted into aminoalkyl substituents by treatment with BOP and the required amine. ${ }^{18}$ This reaction was successful with 13a as a representative pyridopyrimidine substrate affording pentasubstituted pyrido[2,3-d]pyrimidines 15a and 15b in satisfactory yield (55-65\%, Scheme 6).

In the pteridine series, both oxidative substitution and BOP-activated substitution were successful; the former gave a series of 2-alkylamino-4-oxopteridines ( $\mathbf{1 7 a} \mathbf{- h}$ ) in good yield and the latter, 4-aminoalkyl pteridines $(\mathbf{1 8 a}-\mathbf{f})$ in acceptable to good yields ( 65 $80 \%$ ) (Scheme 7). That the order of substitution at C2 and C4 was not critical was shown by the successful oxidative substitution of the new 4-alkylaminopteridines by a variety of amines to give 19a-e although yields were poorer for the BOP-mediated substitution ( $\sim$ 30\%).

### 2.4 Conclusions and Biological activity

In summary, we find that of the fused pyrimidines we have examined in this and in previous work, alkylthiopteridines undergo nucleophilic substitution most readily. ${ }^{19,22}$ Thus in pteridines, substitution after oxidation of the alkylthio group occurred at room temperature in $30-60 \%$ yield with water, azide, primary and secondary amines as nucleophiles. Pyrido[2,3-d]pyrimidines, as described above, are somewhat less reactive, requiring higher temperature and concentration of nucleophile to obtain a good yield. To a small extent, the 7-oxo group, which can assist in the delocalisation of charge in the intermediate in nucleophilic substitution, appears to give better yields. Pyrrolo[2,3$d]$ pyrimidines were the least reactive substrates requiring the use of neat amine as nucleophile and temperatures above $130^{\circ} \mathrm{C}$ to effect substitution; ${ }^{5}{ }^{53}$ this behaviour is consistent with the more electron rich pyrrole fused to the pyrimidine ring. In the pteridine series, substitution at C 2 and C 4 can be undertaken in either order using
oxidation/substitution or BOP activation/substitution chemistry. Taken together, all of these methods provide access to a wide range of fused pyrimidines diversely substituted at a late stage in the pyrimidine ring.

We have described elsewhere how this approach has led to compounds with significant biological activity, especially in antiparasitic applications. ${ }^{53}$ The biological activity of the compounds prepared in this study has been assessed in screens for antibacterial and antiparasitic properties. None of the pyrimido-oxazines was found to be active in any assay used. There was no significant antibacterial activity observed against Staphylococcus aureus, or Escherichia coli, but two of the 4 -oxopteridines, $\mathbf{1 7 g}$ and $\mathbf{1 7 h}$ had weak but measurable activity against the Gram positive bacterium, Nocardia farcinia (MIC $=50$ and $100 \mu \mathrm{M}$ respectively). On the other hand, several 4-amino substituted compounds were hits in a cell based assay against the parasite Trypanosoma brucei brucei. In the pteridine series, both 2-alkylamino and 2-thiobenzyl compounds were active (18a, MIC $=25 \mu \mathrm{M}$; 18c, 12.5; 18d, 25; 18e, 12.5; 18f, 12.5 ; 19c, 3.1; 19d, 3.1; 19e, 6.3); the most active compounds were the 2,4-dialkylamino compounds, 19c-e. The pyridopyrimidin-2,4-dione $\mathbf{1 4 d}$ was a also modest hit with a MIC of $25 \mu \mathrm{M}$. All of these compounds are, however, inferior as antiparasitic compounds to the pyrrolopyrimidines we have already described ${ }^{23}$ because they have unacceptably high values of clogP (67). Nevertheless, the results reported here serve to illustrate the value of diversity oriented synthesis on heterocyclic templates in the discovery of biologically active compounds.

## 3. Experimental

### 3.1 Instrumentation and general methods

NMR spectra were recorded on a Bruker Spectrospin spectrometer operating at 400 MHz for ${ }^{1} \mathrm{H}$ spectra and 100 MHz for ${ }^{13} \mathrm{C}$ spectra. The following abbreviations were used: $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{m}=$ multiplet, $\mathrm{br}=$ broad. Coupling constants $(J)$ are quoted in Hz . Chemical shifts are reported as ppm relative to the residual protio solvent resonance. spectra were determined using a Mattson 1000 FT spectrometer or a Nicolet Impact 400D FT spectrometer as a KBr disc. Mass spectra were measured on a JEOL JMS AX505 spectrometer at the University of Strathclyde using electrospray (ES), or chemical ionisation (CI) methods. Accurate mass were recorded at the University of Glasgow on Jeol JMS-7 MStation high resolution magnetic sector using electron impact (EI) or fast atom bombardment (FAB) ionisation. Melting points, where measurable, were determined on a Reichert hot stage apparatus and are uncorrected. Microanalysis is typically unreliable in
polyazabicyclic compounds due to poor combustion even in the presence of a catalyst $\left(\mathrm{WO}_{3}\right)$; microanalytical data is reported where satisfactory and $400 \mathrm{MHz}{ }^{1} \mathrm{H}$ NMR spectra are included in the Electronic Supplementary Information $\dagger$. TLC was carried out on silica (Merck $0.25 \mathrm{~mm}_{60} \mathrm{~F}_{254}$ ) visualising the plates with either aqueous potassium permanganate solution or UV; whilst suitable for monitoring reactions and product purity, with these highly polar compounds, $\mathrm{R}_{\mathrm{f}}$ values vary from run to run and have therefore not been given. Column chromatography was carried out using silica gel (230-400 mesh; 40-60 mm). All reagents were bought from Aldrich (Gillingham, Dorset, U.K.). Microwave reactions were carried out on a Biotage Initiator 2.0. HPLC was carried out on a Waters machine equipped with a 1525 binary HPLC pump, Waters 2487 dual $\lambda$ absorbance detector, and Breeze software using Vydac protein and peptide C18 column, $\lambda=254 \mathrm{~nm}$. Gradient elution was with water/acetonitrile with or without trifluoroacetic acid.

The reaction mixture was left stirring at $100^{\circ} \mathrm{C}$ for 20 h . The reaction mixture was cooled to room temperature, filtered under vacuum and the solvent evaporated under reduced pressure. The residue was dissolved in water ( 20 mL ) and extracted with $\mathrm{DCM}(50 \mathrm{~mL})$. The organic layers were combined, dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure to give a pale yellow solid. The crude product was purified by column chromatography using ethyl acetate (100\%) as eluant to give 6-(allyloxy)-2-(benzylthio)-pyrimidin-4-amine $\mathbf{2}$ as a pale yellow crystalline solid ( $0.924 \mathrm{~g}, 3.38 \mathrm{mmol}$, $62 \%$ ) and 3-allyl-6-amino-2-(benzylthio)pyrimidin-4(3H)-one 3 as a white crystalline solid $(0.127 \mathrm{~g}, 0.464 \mathrm{mmol}, 9 \%)$.

6-Amino-2-(benzylthio)pyrimidin-4(3H)-one $\mathbf{1}(0.690 \mathrm{~g}, 2.95 \mathrm{mmol})$ was dissolved in DMF ( 12 mL , anhydrous) at room temperature under nitrogen. Ethyl 2-(bromomethyl)acrylate ( $610 \mu \mathrm{l}, 4.40 \mathrm{mmol}, 1.50 \mathrm{eq}$.) and potassium carbonate ( $0.500 \mathrm{~g}, 3.62 \mathrm{mmol}, 1.23 \mathrm{eq}$.) were added and the reaction mixture was stirred at $55^{\circ} \mathrm{C}$ for 24 h . Once the reaction was complete (confirmed by TLC), the mixture was cooled to room temperature and the solvent evaporated under reduced pressure. The subsequent yellow oil was dissolved in DCM, the organics were extracted with brine and dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure to give a yellow oil. Purification of the crude product was achieved using column chromatography using ethyl acetate:hexane ( $1: 1$ ) as eluant. The title compound $\mathbf{5}$ was isolated as a white solid $(0.114 \mathrm{~g}, 0.249 \mathrm{mmol}, 8 \%)$, m.p. $110-112{ }^{\circ} \mathrm{C} . v_{\max }(\mathrm{KBr}): 3407,3323,3191,2991,1707$, 1652, 1572, 1493, 1474, 1444, 1401, 1376, 1316, 1264, 1158, 1050, 956, 855, 776, $563 \mathrm{~cm}^{-1}$;

### 3.2.56 2-(Benzylsulfanyl)-6,7,7-trimethyl-3,7-dihydro-4H-pyrimido[4,5-b][1,4]oxazin-4one 20

2-(Benzylthio)-6-hydroxy-5-nitrosopyrimidin-4(3H)-one (300 mg, 1.14 mmol ) was dissolved in ethanol ( 20 mL ) to which sodium dithionite ( $496 \mathrm{mg}, 2.85 \mathrm{mmol}, 2.5 \mathrm{eq}$ ) in water ( 20 mL ) was added dropwise at room temperature and allowed to stir for 4 h . The flask was covered with aluminium foil to protect from light. A light yellow solid was precipitated, which was filtered and washed with water $(2 \times 10 \mathrm{~mL})$ and ether $(2 \times 10 \mathrm{~mL})$. The resulting solid was suspended in a $1: 1$ water/ethanol mixture ( 20 mL ). 3-Chloro-3-methylbutan-2-one ( 206 mg , $1.5 \mathrm{eq})$ in ethanol ( 10 mL ) was then added to the suspension and this mixture was heated to reflux. After 15 min sodium acetate ( $112 \mathrm{mg}, 1.2 \mathrm{eq}$ ) in water ( 5 mL ) was added dropwise and heating under reflux was continued for a further 3 h . The resulting mixture was allowed to cool to room temperature and then stored at $0^{\circ} \mathrm{C}$ for 12 h . The resulting precipitate was filtered, washed with water $(2 \times 10 \mathrm{~mL})$ and dry ether $(2 \times 10 \mathrm{~mL})$ to yield the title compound 20 as a beige solid ( $126 \mathrm{mg}, 0.399 \mathrm{mmol}, 35 \%$ ), m.p. $222-224^{\circ} \mathrm{C} . v_{\max }(\mathrm{KBr}): 3424,2981$, $1658,1561,1312,1239,1121,965,705 ; \mathrm{cm}^{-1} ; \delta_{\mathrm{H}}\left(\mathrm{DMSO}_{6}\right): 1.44\left(6 \mathrm{H}, \mathrm{s}, 7-\mathrm{CH}_{3} \mathrm{x} 2\right), 2.07$ $\left(3 \mathrm{H}, \mathrm{s}, 6-\mathrm{CH}_{3}\right), 4.36\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2} \mathrm{~S}\right), 7.41-7.20\left(5 \mathrm{H}, \mathrm{m}, \mathrm{C}_{6} \mathrm{H}_{5}\right), 12.63(2 \mathrm{H}, \mathrm{br}$ s, NH$)$. ## Abbreviations for reagents

| BOP | (1-benzotriazolyl)oxy tris(dimethylamino) phosphonium <br> hexafluorophosphate |
| :--- | :--- |
| $m$-CPBA | $m$-chloroperbenzoic acid |
| DBU | 1,8 -diazabicyclo[5,4,0]undec-7-ene |
| TBD | $1,5,7$-triazabicyclo[4.4.0]dec-5-ene |

Scheme 1. Substitution by Claisen rearrangement.Reagents and conditions: i. DMF, $\mathrm{K}_{2} \mathrm{CO}_{3}$, $100^{\circ} \mathrm{C}, 20 \mathrm{~h} ;$ ii. $200^{\circ} \mathrm{C}, 24 \mathrm{~h}$

Scheme 2. Preparation of dialkylated pyrimidine 5 Reagents and conditions: i. DMF, $\mathrm{K}_{2} \mathrm{CO}_{3}, 55{ }^{\circ} \mathrm{C}, 24 \mathrm{~h}$

Scheme 3. Reagents and conditions: i. DMF, r.t, 7 d; ii. TBD or DBU, MW, $100^{\circ} \mathrm{C}, 30$ min

Scheme 4. Regents and conditions: i. $\mathrm{Cs}_{2} \mathrm{CO}_{3}$, KI , r.t., 24 h ; ii. $\mathrm{TiCl}_{4} .2 \mathrm{THF}$, THF, reflux, 3 d

Scheme 5. Proposed mechanism for the synthesis of derivatives 11

Scheme 6. Diversification reactions for pyrrolopyrimdines. Reagents and conditions: i. DMF, $m$-CPBA, r.t., 3 h ; $i i$, appropriate amine, MW, $110^{\circ} \mathrm{C}, 1 \mathrm{~h}$; iii, BOP, CHCN, r.t., 10 min ; $i v$, DBU, appropriate amine, r.t., 48 h .

Scheme 7. Diversification reactions for pteridines. Reagents and conditions: $i, \mathrm{HNO}_{2} ; i i$, $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{4}$; iii, EtOH, reflux; $i v$, DMF, $m$-CPBA, r.t., 3 h ; $v$, appropriate amine, MW, $110^{\circ} \mathrm{C}, 1$ h ; vi, $\mathrm{BOP}, \mathrm{CH}_{3} \mathrm{CN}$, r.t., 10 min ; vii, DBU, appropriate amine, r.t., 48 h .

Scheme 8. Diversification for pyrimidooxazines. Reagents and conditions: $i, \mathrm{HNO}_{2} ; i i$, $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{4}$; iii, aq. EtOH, NaOAc, reflux; i iv $\mathrm{PhCH}_{2} \mathrm{NH}_{2}$, MW, $110^{\circ} \mathrm{C}, 1 \mathrm{~h}$.
