18

19 **At a Glance Commentary:** Females develop pulmonary arterial hypertension
20 (PAH) more frequently than males. The role of estrogen in this female susceptibility
21 is poorly understood. Our research shows that inhibition of endogenous estrogen
22 synthesis using an aromatase inhibitor or inhibition of estrogen receptor alpha has
23 therapeutic effects and restores BMPR2 expression in female but not male models of
24 PAH. These findings suggest estrogen plays a pathogenic role in the pathology of
25 PAH specifically in females

1 **Abstract**

2 **Rationale:** The incidence of pulmonary arterial hypertension (PAH) is greater in
3 women suggesting estrogens may play a role in the disease pathogenesis.
4 Experimentally, in males, exogenously administered estrogen can protect against
5 PH. However, in models that display female susceptibility, estrogens may play a
6 causative role.

7 **Objectives:** To clarify the influence of endogenous estrogen and gender in PH and
8 assess the therapeutic potential of a clinically available aromatase inhibitor.

9 **Methods:** We interrogated the effect of reduced endogenous estrogen in males and
10 females using the aromatase inhibitor, anastrozole, in two models of PH; the hypoxic
11 mouse and Sugden 5416/hypoxic rat. We also determined the effects of gender on
12 pulmonary expression of aromatase in these models and in lungs from PAH patients.

13 **Results:** Anastrozole attenuated PH in both models studied, but only in females. To
14 verify this effect was due to reduced estrogenic activity we confirmed that in hypoxic
15 mice inhibition of estrogen receptor alpha also has a therapeutic effect specifically in
16 females. Female rodent lung displays increased aromatase and decreased BMPR2
17 and Id1 expression compared to male. Anastrozole treatment reversed the impaired
18 BMPR2 pathway in females. Increased aromatase expression was also detected in
19 female human pulmonary artery smooth muscle cells compared to male.

20 **Conclusions:** The unique phenotype of female pulmonary arteries facilitates the
21 therapeutic effects of anastrozole in experimental PH confirming a role for
22 endogenous estrogen in the disease pathogenesis in females and suggests
23 aromatase inhibitors may have therapeutic potential.

24 **Word count:** 238 **Keywords:** pulmonary hypertension, estrogen, gender.

1 **Introduction**

2

3 Pulmonary arterial hypertension (PAH) is characterised by severe pulmonary arterial
4 remodelling and occlusive pulmonary vascular lesions, leading to right ventricular
5 failure. Epidemiological studies report a greater incidence of the disease in females;
6 depending on the disease classification the female to male ratio can be as great as
7 4:1 (1, 2). The female predisposition to PAH has given rise to the hypothesis that
8 female sex hormones, primarily estrogens, may play a causative role in the
9 development of the condition (3). However, the role of estrogen in PAH remains
10 controversial.

11 The majority of preclinical studies into the role of estrogens in PH have utilised male
12 animals (4-6) and describe protective effects of estrogen when administered
13 exogenously. However, there is compelling evidence that endogenous estrogen
14 may contribute to the pathogenesis of PH. Recently, we have described novel
15 murine models where only female animals develop PH such as mice over-
16 expressing the serotonin transporter gene (SERT+ mouse) (7) and Mts1(8). In these
17 models the predominant circulating estrogen 17 β -estradiol plays an essential role in
18 the development of the PH phenotype (7-9). Estrogen can also induce proliferation
19 of human pulmonary artery smooth muscle cell (hPASMCs) and may therefore
20 contribute to the pulmonary artery remodelling observed in PAH (7, 10).

21 One explanation of the current controversies is that there are gender differences in
22 the influence of endogenous estrogens on the pathophysiology of PH. Determining
23 any gender differences in pulmonary responses to estrogen is vitally important for
24 understanding the nature and origins of PAH. To our knowledge, there have been
25 no comprehensive male *versus* female comparative studies into the role of
26 *endogenous* estrogen in the pulmonary circulation.

1 Aromatase (CYP19A1), a member of the cytochrome P450 superfamily, synthesizes
2 estrogens through the aromatization of androgens. In pre-menopausal women
3 estrogen synthesis occurs mainly in the ovarian follicles and corpus luteum, but also
4 to a lesser extent in non-glandular tissues such as adipose tissue and liver. In
5 postmenopausal women and men, adipose tissue is a major source of estrogen (11).
6 Little is known of the role aromatase plays within the pulmonary circulation.
7 Therefore, to characterise the role of endogenous estrogen in PAH, the effects of an
8 aromatase inhibitor were studied in two models of PH in male and female animals.
9 We also assessed aromatase expression in the lung tissue of these animal models
10 and in lung samples from PAH patients.

11

12

13 **Methods**

14 An expanded methods section is available in the Online Supplement

15 *Hypoxic Studies*

16 **The ability of anastrozole to reduce progression of, and reverse, established PH in**
17 **hypoxic mice was assessed.** Hypoxic PH in C57BL/6 mice was achieved with 14
18 days hypoxia as described previously (10, 12). Mice were then maintained in
19 hypoxic conditions for a further 14 days during which time the aromatase inhibitor,
20 anastrozole was administered (Tocris) 0.3 mgkg^{-1} or 3 mgkg^{-1} or vehicle (1%
21 carboxymethylcellulose) daily (s.c.). Another cohort of mice were administered with
22 an ER \pm antagonist, MPP $2 \text{ mgkg}^{-1}\text{day}^{-1}$ for 14days (s.c.). Age-matched mice housed
23 in normoxic conditions were studied as controls. See online supplement for ethical
24 considerations and housing details.

1 *Sugen 5416 + hypoxia (Su/Hx) Study*

2 The ability of anastrozole to reduce progression of, and reverse, established PH was
3 also assessed in the rat model of hypoxia + Sugen5416 (Su) as described in detail in
4 online supplement. Briefly, Wistar Kyoto rats were given a single injection of Su
5 20mgkg^{-1} (s.c.) or 0.9% (s.c.) saline and exposed to hypoxia for 14 days then
6 retained in normoxia for two weeks during which time they were dosed with
7 anastrozole (0.03 , 0.3 or $3\text{ mgkg}^{-1}\text{day}^{-1}$) or vehicle (1% carboxymethylcellulose)
8 orally.

9

10 *Hemodynamic Measurements*

11 Heart rate, right ventricular systolic pressure (RVSP), systemic arterial pressure and
12 cardiac output were measured and analyzed as previously described (10, 12, 13).
13 See online supplement for details.

14

15 *Right Ventricular Hypertrophy*

16 Right ventricular hypertrophy (RVH) was assessed by weighing the right ventricular
17 free wall and left ventricle plus septum. The ratio expressed as $\text{RV}/\text{LV}+\text{S}$. See
18 online supplement for details.

19

20 *Lung Histopathology*

21 $3\mu\text{m}$ lung sagittal sections were stained with \pm -smooth-muscle actin ($<80\mu\text{m}$
22 external diameter) and microscopically assessed for degree of muscularisation in a
23 blinded fashion, as previously described (14) and in online supplement.

24

25

1 *qRT-PCR*

2 mRNA expression was assessed in lungs of mice by qRT-PCR as described
3 previously and in online supplement (10).

4

5 *Immunoblotting*

6 Protein expression was assessed by immunoblotting in lung and hPASCs as
7 described previously and in online supplement (10).

8

9 *Lung Immunolocalization*

10 Aromatase expression was investigated in murine, rat and human lung by
11 immunohistochemistry as described previously and in online supplement (10).

12

13 *Measurement of Estradiol Concentrations.*

14 Circulating estradiol was quantified in plasma by ELISA (Estradiol ELISA, Life
15 Technologies).

16

17 *hPASCs and PAH-PASCs*

18 hPASCs were prepared and cultured as described previously and in online
19 supplement (10).

20

21 *Statistics*

22 All data are expressed as mean \pm SEM. Data were analysed using one-way ANOVA
23 with Dunnett's or Bonferroni post-hoc analyses and Student's unpaired t-test (as
24 appropriate and indicated in figure legends) using GraphPad Prism 5 software. A P
25 value < 0.05 was considered statistically significant.

1 **Results**

2

3 *Inhibition of aromatase attenuates experimental PH in female but not male mice.*

4 In female mice anastrozole reduced hypoxia-induced increases in RVSP, RVH and
5 pulmonary vascular remodelling (PVR) (Figure 1A-D). However, in male mice,

6 anastrozole when used at the most effective dose ($3\text{mgkg}^{-1}\text{day}^{-1}$) had no significant
7 effect on hypoxia-induced elevations in RVSP, RVH or PVR (Figure 1E-H).

8 Anastrozole had no significant effect on mean systemic arterial blood pressure or
9 heart rate (Figure E1 online supplement).

10 To confirm that this effect was not due to any off-target effects of anastrozole, the
11 effect of MPP, an ER \pm antagonist was assessed. MPP was selected as ER \pm protein
12 levels were found to be significantly elevated in pulmonary arteries from female
13 hypoxic mice, whilst ER 2 was significantly reduced. No significant differences in the
14 expression of ER \pm or ER 2 were observed in pulmonary arteries from male mice
15 (Figure E2 online supplement). MPP markedly attenuated hypoxia-induced
16 increases in RVSP and PVR in females but had no therapeutic effect in males
17 (Figure E3 online supplement).

18 In female Su/Hx rats anastrozole reduced increases in RVSP, RVH, PVR and
19 **reversed** the development of occlusive vascular lesions (Figure 2A-E). In contrast to
20 females, anastrozole had no significant effect on Su/Hx-induced changes in RVSP,
21 RVH or PVR in male animals (Figure 3A-E).

22 Cardiac and pulmonary function were assessed by echocardiography. In female rats
23 anastrozole had no effect on cardiac output, but did slightly **restore** decreased
24 pulmonary artery acceleration time (PAAT) (Figure E4 online supplement). In Su/Hx

1 male rats anastrozole had no effect on cardiac output or PAAT (Figure E4 online
2 supplement).

3

4 *Aromatase expression in hypoxic and Su/Hx-induced PH.*

5 Weak aromatase expression was observed in pulmonary arteries from normoxic
6 mice whilst expression was abundant in hypoxic mice, localising to the smooth
7 muscle layer (Figure 4A). Analysis of whole lung tissue by immunoblotting showed
8 that female mice express significantly higher levels of aromatase protein in whole
9 lung compared to male in both normoxic and hypoxic conditions (Figure 4B).
10 Similarly, in pulmonary arteries from normoxic rats negligible to weak aromatase
11 staining was observed whilst expression was abundant in arteries from Su/Hx rats,
12 localising within the vascular smooth muscle (Figure 5A). **Aromatase staining was**
13 **absent from the endothelial layer of rat pulmonary arteries (Figure 5B). In addition,**
14 **aromatase was absent from endothelial cells within the small occlusive vascular**
15 **lesions observed in Su/Hx rat lung (Figure 5C).** Male rats also express significantly
16 lower aromatase protein levels in the whole lung compared to female under both
17 normoxic and Su/Hx conditions (Figure 5D). Exposure to Su/Hx had no effect on
18 aromatase expression in female or male rat lung when compared to normoxic control
19 (Figure 5D).

20

21 *Aromatase expression in human lung.*

22 Aromatase was found to be expressed in pulmonary arteries of control, female PAH
23 and male PAH patients localising mainly within the smooth muscle layer (Figure 6A).
24 Aromatase immunostaining was also present in vascular lesions from PAH patients
25 (Figure 6B) also localising to the smooth muscle layer. **Aromatase immunoreactivity**

1 was absent in the endothelium of most PAH patients regardless of BMPR2 status
2 (Figure 6B and E5B). In addition, there was no evidence of aromatase expression in
3 human microvascular pulmonary artery endothelial cells (hMPAECs) (Figure E5C
4 online supplement). PSMCs isolated from control postmenopausal females
5 express significantly higher levels of aromatase than those from males (Figure 6C),
6 however, no significant difference in aromatase expression in PSMCs from female
7 control *versus* female PAH patients was observed (Figure 6D).

8
9 *Effect of anastrozole on circulating estrogen levels.*

10 Anastrozole 0.3mgkg^{-1} and 3mgkg^{-1} decreased levels of circulating estradiol, the
11 major bioactive estrogen in female mice and had no effect on circulating estrogen
12 levels in the male mice. Furthermore, hypoxia alone had no effect of circulating
13 estrogen levels in either female or male mice (Figure 7A)

14 In the Su/Hx rat model, estradiol levels were undetectable in male rats. However, in
15 female rats, circulating estradiol levels were found to be significantly elevated in the
16 Su/Hx rats compared to normoxic controls (Figure 7B). Anastrozole reduced
17 circulating estradiol levels in a dose-dependent fashion. Analysis across the female
18 Su/Hx treatment groups revealed a significant correlation between circulating
19 estradiol concentrations and RVH (Figure 7C) as well as the percentage of
20 muscularised pulmonary arteries (Figure 7D).

21
22 *Effects of anastrozole on hypoxia and Su/Hx-mediated changes in bone*
23 *morphogenetic protein receptor 2 (BMPR2).*

24 In normoxic conditions lung transcript levels of BMPR2 were significantly lower in
25 female mice than male. Administration of anastrozole resulted in a significant

1 upregulation of BMPR2 in female lung, restoring levels to that of males whilst having
2 no effect on BMPR2 levels in male lung (Figure 8A). In hypoxia, BMPR2 transcript
3 and protein levels were significantly reduced in both male and female lung.
4 Anastrozole treatment restored the hypoxia-mediated downregulation in BMPR2 in
5 females (Figure 8A-B) but not males (Figure 8A&C). In the Su/Hx rat model, BMPR2
6 transcript was also found to be significantly decreased in both male and female lung
7 compared to normoxic controls (Figure 8D-F). This effect was reversed in female
8 rats treated with anastrozole $3\text{mgkg}^{-1}\text{day}^{-1}$ (Figure 8D-E) but not male rats (Figure
9 8F). The male rats had significantly higher normoxic transcript levels of BMPR2
10 compared to females, consistent with our observations in mice (Figure 8D).

11 Female normoxic mouse and rat lung demonstrated significantly lower levels of Id1
12 and Id3 (Figure E6 online supplement) than males. In females anastrozole
13 significantly elevated Id1 and Id3 to levels similar to that observed in males but had
14 no effect on Id1 and Id3 expression in male lung. Id1 expression was significantly
15 reduced in both male and female disease models, whilst Id3 was specifically
16 downregulated in males. The PH-mediated decreases in Id1 were rescued by
17 administration of anastrozole in female animals but not male (Figure E6 online
18 supplement). ER \pm antagonist MPP also restored hypoxia-mediated reductions in
19 BMPR2 and Id1 (Figure E7 online supplement).

20

21

22 **Discussion**

23

24 Increased synthesis of estrogen has been clinically associated with porto-pulmonary
25 hypertension (15) and estrogen is causative in female susceptible models of PH (7-

1 9). Studies into the role of estrogen in PAH have failed to reach a consensus, mainly
2 due to the variety of experimental approaches adopted. Indeed, many experimental
3 studies have demonstrated a protective effect of estrogen in male animals (4-6).
4 These valuable studies examined the influence of estrogen administered to males
5 where estrogen levels are normally extremely low or undetectable. In addition, these
6 studies utilise intact males, hence the presence of high endogenous testosterone
7 combined with high circulating estrogen levels (due to the exogenously added
8 estradiol) are not a state that would normally occur physiologically and may influence
9 interpretation of results. In the instance of monocrotaline (MCT)-induced PH the
10 beneficial effects of estrogen may be owing to the fact that MCT is a toxin reported to
11 cause gonadal toxicity and reduce estrogen levels (16). In our experimental design
12 we wished to compare males and females and address a different question: 'what is
13 the role of *endogenous* estrogen and is it different in intact males and females?'
14 The data presented in this study explains some of these current controversies by
15 providing several unique insights into the influence of gender and endogenous
16 estrogen in the development of PH. We demonstrate that endogenous estrogen
17 **contributes to the pathophysiology** of PH in females and that there is potential for
18 local estrogen synthesis in PSMCs. Given the previously demonstrated mitogenic
19 effects of estrogen in PSMCs (7), we **also** describe a unique pro-proliferative
20 phenotype in female PSMCs owing to elevated aromatase and reduced BMPR2
21 and Id1 expression.

22 Using anastrozole we inhibited the enzyme aromatase, which is responsible for
23 estrogen synthesis, to determine the role of endogenous estrogen **on established** PH
24 in females and males. Anastrozole reduced plasma estrogen and attenuated
25 hypoxia and Su/Hx-induced changes in RVSP, RVH and PVR in females.

1 Furthermore, in the female Su/Hx model a positive correlation between circulating
2 estrogen concentrations and disease severity was established, suggesting the
3 therapeutic effects of anastrozole were related to a decrease in plasma estrogen
4 levels. In the males, there was no therapeutic effect of anastrozole; plasma estrogen
5 was below the level of detection and unaffected by anastrozole.

6 We also demonstrated that there is a dysregulation in the expression of estrogen
7 receptors in hypoxic female mice but not male, with ER \pm expression significantly
8 increased and ER 2 decreased in female pulmonary artery whilst both receptors
9 remain unaffected in males. Furthermore, we show that an ER \pm antagonist, MPP,
10 has selective therapeutic effect in female hypoxic mice, not male. This corroborates
11 our hypothesis that endogenous estrogen is pathogenic in female models of PH.
12 Anastrozole is a third generation highly selective competitive inhibitor of aromatase
13 and as such has few off-target actions. Preclinical studies show that even when
14 used up to doses of 10mgkg $^{-1}$ in rats no reported disturbances in adrenal
15 steroidogenesis were observed (17).

16 Estrogen is widely described to be cardioprotective due to its direct action on the
17 heart. Epidemiological evidence shows that pre-menopausal women have a lower
18 risk for mortality from cardiovascular diseases than men (18-20). Given the
19 cardioprotective effects of estrogen there is concern that treatment with aromatase
20 inhibitors may facilitate right ventricular dysfunction. Hence we interrogated the
21 influence of anastrozole on heart function in the Su/Hx rat model by
22 echocardiography. Anastrozole had no detrimental effects on cardiac output or
23 pulmonary artery acceleration time in rats. These findings suggest that depletion of
24 estrogen is not having detrimental effects on the heart that might limit the use of
25 anastrozole in the treatment of PAH. Aromatase inhibitors are currently widely

1 prescribed to patients with estrogen receptor-sensitive breast cancer and many
2 systemic side-effects have been investigated. Available data do not support an
3 association between aromatase inhibitors and an increased risk of cardiovascular
4 disease, PAH or a deleterious effect on lipid metabolism in humans (21).

5 Aromatase was expressed in small pulmonary arteries of both female and male
6 rodents localising within the smooth muscle layer. However, aromatase expression
7 was significantly higher in the lungs from female rats and mice than males. This may
8 partially explain the increased therapeutic effect of anastrozole in the females. We
9 also verified that aromatase is expressed in the smooth muscle of pulmonary arteries
10 in human lung, demonstrating that aromatase is abundantly expressed in vascular
11 smooth muscle from control non-PAH lung sections and in complex vascular lesions.
12 This coupled with the elevated aromatase expression observed in female PSMCs
13 suggests female PSMCs have the ability to synthesis higher levels of estradiol than
14 male. This may contribute to the female susceptibility to PAH given the mitogenic
15 properties of estradiol.

16 This is the first study to report that there is the potential for local estrogen production
17 in pulmonary arteries. **We could find no evidence for aromatase expression in the**
18 **endothelium of rats, mice or human in our studies regardless of their disease status.**
19 **Likewise, hMPAECs do not express aromatase.** This suggests that estrogen
20 produced by PSMCs that exerts a paracrine proliferative effect on adjacent
21 PSMCs. Indeed, we have previously demonstrated that estrogen induces
22 proliferation in human PSMCs (7, 8). Estrogen synthesized within extragonadal
23 compartments has been postulated to act at a local tissue level in a paracrine
24 fashion (22). Thus, the total amount of estrogen synthesized by these extragonadal
25 sites may be small but the local tissue concentrations achieved high enough to exert

1 significant biologic influence locally (11). Given the expression of aromatase in the
2 smooth muscle layer of the pulmonary artery the local concentration of estrogen in
3 the pulmonary artery may be much greater than circulating concentrations. Estrogen
4 levels will also be affected by metabolism. We have previously shown that
5 expression of cytochrome P450 1B1 (CYP1B1) an estrogen metabolising enzyme is
6 dysregulated in the Su/Hx mouse model of PH (10). Differences in estrogen
7 metabolism between the hypoxic mouse model and Su/Hx rat model of PH may
8 explain why circulating estrogen levels are elevated in Su/Hx rats but not hypoxic
9 mice.

10 Loss of function associated with BMPR2 mutations in PAH results in reduction of the
11 growth inhibitory effects of BMPs, facilitating the proliferation of PASMCs and
12 contributing to pulmonary vascular remodelling (23). BMPR2 is also often observed
13 to be down-regulated in animal models of PAH (24, 25). Here we showed that
14 expression of BMPR2 and its downstream mediator Id1 are significantly decreased
15 in the lungs of normoxic female rodents compared with males. The significantly
16 lower levels of BMPR2 and Id1 in females can be restored to levels similar to that
17 observed in males by anastrozole, suggesting estrogen may be responsible for the
18 suppressed BMPR2 signaling axis in females. Furthermore, anastrozole treatment
19 restored hypoxic and Su/Hx-mediated reductions in BMPR2 mRNA and protein
20 levels in female rodents whilst having no effect on males. These observations
21 provide one further explanation for the selective therapeutic effect of anastrozole on
22 the development of PH in female models, i.e. endogenous estrogen in the lungs of
23 females is greater due to increased aromatase expression; this combined with the
24 effects of hypoxia or Su/Hx, decreases expression of BMPR2 which is already

1 significantly reduced in females. Consequently anastrozole, by decreasing
2 endogenous estrogen levels, has a selective therapeutic effect in females.

3 In hPAH families, penetrance of PAH in BMPR2 mutation carriers is low, suggesting
4 other risk factors must influence the emergence of the PAH phenotype. Indeed,
5 further predisposing genes such as KCNK3 and TOPBP4 have been recently
6 identified (26, 27). Whilst increased aromatase expression combined with
7 decreased BMPR2 signaling may predispose susceptible females to PAH it is
8 unlikely that these factors alone are responsible for the clinical presentation of
9 disease in all females; and clearly males develop PAH, displaying poorer survival
10 rates than females (1). Our results suggest that once the disease is established, the
11 increased influence of both circulating and locally produced estrogen in women,
12 results in an enhanced pathogenic effect on the pulmonary circulation compared to
13 males. Consistent with this, female PAH patients have 2.8-fold higher number of
14 plexiform lesions compared with their male counterparts (20).

15 However, in some patient sub-groups including PAH associated with HIV, sleep
16 apnea and portopulmonary hypertension the prevalence of PAH is greater in males
17 (1). However, these primary conditions occur more frequently in men, potentially
18 influencing the male:female ratio of those developing PAH (e.g.(28-30)). In addition,
19 estrogen may contribute to the disease pathophysiology in males within these
20 subgroups. For instance, in HIV dysregulation in sex hormone concentrations have
21 been reported in both sexes. In one study estradiol was reported to significantly
22 increase over an 18 month period in male HIV patients (31). Furthermore,
23 obstructive sleep apnea is most common in obese men (29), in which elevated
24 circulating estrogen levels are common due to the high expression and activity of
25 aromatase within adipose tissue (32, 33). Polymorphisms in the aromatase gene

1 have also been associated with increased risk of portopulmonary hypertension in
2 patients with liver disease. These polymorphisms are associated with increased
3 estradiol production, supporting a functional effect of aromatase activity in both male
4 and female patients (15). Thus, elevated estrogen is observed in the males in these
5 PAH subgroups. This is not incompatible with the suggestion that when elevated,
6 endogenous estrogen may contribute to the pathobiology PAH in males as well as
7 females.

8 The results of this study also suggests that non-estrogenic contraceptives be
9 recommended to pre-menopausal PAH patients, although these are already contra-
10 indicated for PAH patients due to the increased risk of venous thromboembolic
11 disease (34).

12 In summary, we have demonstrated that endogenous estrogen plays a causative
13 role in the development of experimental PH in female animal models of the disease.
14 Inhibition of aromatase with anastrozole reduces moderate and severe experimental
15 PH in female animals via reduction in endogenous estrogen. The reason for the
16 sexual dimorphism in the therapeutic effects of anastrozole may be due to a unique
17 phenotype of female pulmonary arteries. We propose that increased capability of
18 female PSMCs to produce estrogen locally via aromatase contributes to a
19 reduction in the BMPR2 signalling axis and may contribute to the pathology and
20 increased incidence of the disease in females. The results partly explain the
21 'estrogen paradox' and suggest that aromatase inhibitors may have therapeutic
22 potential in the treatment of PAH in females.

Gender-dependent Influence of Endogenous Estrogen in Pulmonary Hypertension.

Kirsty M. Mair, Audrey F Wright, Nicholas Duggan, David J. Rowlands, Martin J. Hussey, Sonia Roberts, Josephine Fullerton, Margaret Nilsen, Lynn Loughlin, Matthew Thomas & Margaret R. MacLean.

Supplemental Methods

Ethical Information

All animal procedures conform to the UK Animal Procedures Act (1986) and the *Guide for the Care and Use of Laboratory Animals* published by the US National Institutes of Health (NIH publication No. 85–23, revised 1996). Experimental procedures using human lung tissue and hPASMCs conform to the principles outlined in the Declaration of Helsinki and were approved by Cambridgeshire 1 Research Ethics committee (REC reference: 08/H0304/56). All non-PAH human lung biopsies were confirmed as macroscopically normal and collected from patients undergoing pneumonectomy with no reported presence of PAH.

Animals

Male and female C57BL/6 mice (aged 8-12 weeks) and Wistar Kyoto rats (~200g) were purchased from Harlan, UK. Rodents were housed in a 12-hour light-dark cycle with access to food and water ad libitum. Animals were housed together to promote synchronisation of the estrous cycle. **The method we employ to check the estrous cycle in cohorts of mice is as follows. All female mice are housed together for two weeks prior to the study. A blunt, shortened tip of a Pasteur pipette is placed at the vaginal orifice. One drop of PBS is gently expelled into the vagina and aspirated back before being transferred to a microscope slide. Smears are examined microscopically and classified as to the stage of the cycle according to criteria modified from those of Nelson *et al.*, (1). Our analysis indicates that even after 4 days female mice start to synchronise and by two weeks we are convinced that they**

are fully synchronised. In addition, plasma levels of estrogen are very consistent and within a tight range for our female study animals.

In Vivo Effects of MPP Dihydrochloride Administration

Prior to the induction of hypoxia, C57Bl/6 mice were administered with either ER± antagonist, MPP dihydrochloride [chemical name- 1,3-Bis(4-hydroxyphenyl)-4-methyl-5-[4-(2-piperidinyloxy)phenol]-1H-pyrazole dihydrochloride] (MPP) 2 mgkg⁻¹day⁻¹ or vehicle. Under general anaesthesia (1% - 3% (v/v) isoflurane supplemented with O₂) pellets containing either ER± antagonist, MPP (0.56mg/14 day pellet, Innovative Research of America, Florida, USA) or vehicle were inserted subcutaneously into the dorsal neck of male and ovary intact female mice using a sterile 12-gauge hypodermic needle. The development of PH was then assessed in normoxic animals and animals exposed to hypobaric hypoxia (550mbar, equivalent to 10% O₂) for 14 days in the presence of MPP or vehicle. n=6-10 mice per experimental group.

Sugen 5416+hypoxia

The underlying concept is that two hits are required to generate severe obliterative PH in the rat. Su5416 binds with high affinity to the intracellular tyrosine kinase domain of VEGFR1 (flt1) and VEGFR2 (KDR) and inhibits signal transduction via these receptors, inducing lung endothelial cell apoptosis (2). Su5416-induced pulmonary endothelial cell apoptosis in combination with chronic hypoxia results in the development of angioproliferation and obliterative pulmonary vascular lesions (3).

The vascular endothelial growth factor receptor inhibitor Sugen (Su) 5416 was suspended in 0.5% (wt/vol) carboxymethylcellulose sodium, 0.9% (wt/vol) NaCl, 0.4% (vol/vol) polysorbate, and 0.9% (vol/vol) benzyl alcohol in dH₂O. Rats (~200g) were administered with a single injection of Su5416 (Sigma UK, 20 mgkg⁻¹ s.c.) or 0.9% saline and exposed to chronic hypoxia for 14 days. At this point, a sub-set of animals were taken for hemodynamic and histological analysis. The remaining rats were subsequently transferred to normoxic conditions for a further 14 days during which time they received the aromatase inhibitor anastrozole 0.03, 0.3 or 3 mgkg⁻¹day⁻¹ or vehicle (1% carboxymethylcellulose) by oral administration. Vehicle dosed rats housed in normoxic conditions only were studied as controls.

Echocardiographic Assessment and pressure measurements in rats

In rats, right ventricular systolic pressure was measured by right heart catheterization through the right jugular vein (MPVS-300 System; Millar, Houston, TX).

Echocardiographic assessments were performed by ultrasound on 2% isoflurane-anesthetized animals. A Vivid7 (GE Healthcare, Little Chalfont, Buckinghamshire, UK) ultrasound system equipped with 13-MHz probe was used. The pediatric probe was placed in a parasternal long axis position to visualize the PA outflow tract. Pulsed flow Doppler imaging was then overlaid to observe the dynamics of blood flow through the PA valve. Changes in PA acceleration/ejection time ratio (time taken from start of flow to maximal velocity or to the end of flow) were determined. The cardiac function was further analyzed by cardiac output (CO) values as previously described (4). Analysis was performed using Echo-PAC dimension software.

Right Ventricular Hypertrophy

Right ventricular hypertrophy (RVH) in mice was assessed by weight measurement of the right ventricular free wall and left ventricle plus septum. The ratio expressed is RV/LV+S.

Lung Histopathology

3µm lung sagittal sections were stained with elastic Van Gieson and pulmonary arteries (<80 µm external diameter) microscopically assessed for degree of muscularisation in a blinded fashion, as previously described (5). Remodelled arteries were confirmed by the presence of double-elastic laminae. Briefly, percentage remodelling (percent of remodelled vessels) was defined for each animal by the number of remodelled vessels divided by the total number (e80 per lung) of vessels observed in the lung. To visualize the degree of smooth muscle thickening, lungs were stained with α -smooth muscle actin (Abcam, UK). Briefly, 3 µm sagittal sections were deparaffinised and rehydrated through a xylene-ethanol gradient. After epitope retrieval, endogenous peroxidase and biotin activity was blocked and lung tissue was incubated for 16 hours with anti-rabbit α -smooth muscle actin antibody (dilution 1:1000 Abcam, UK) or IgG control. After secondary incubation, α -smooth muscle actin was visualized with the DAB substrate kit (Vector Laboratories, UK), which stained brown/dark brown. The presence and degree of pulmonary vascular occlusion formation were assessed in lungs from chronic hypoxic+SU5416-treated rats as previously described (5). Images were captured using a Zeiss Axio Imager M1.

Quantitative Reverse Transcription–Polymerase Chain Reaction

mRNA expression was assessed in the lungs of mice by quantitative reverse transcription–polymerase chain reaction. At necropsy, lung tissue from each rodent was removed and snap frozen. RNA was then extracted from the lung tissue or pulmonary artery smooth muscle cells and gene expression quantified using TaqMan® gene expression assays (assay details shown in Supplemental Table 1). ViiA7 Real-time PCR system (Applied Biosystems) was programmed for PCR conditions 95°C for 10 minutes followed by 50 cycles of 95°C for 15 seconds and 60°C for 1 minute. Results were normalised to β -2-microglobulin. The fold change for every gene was obtained using the $2^{-\Delta\Delta Ct}$ method and expressed relative to normoxic female mice or rats as appropriate.

Immunoblotting

Protein expression was assessed in whole lung. Briefly, lung tissue was homogenised in radioimmunoprecipitation assay buffer via ultrasonic homogenization. Samples were denatured and electrophoresed on SDS-PAGE gel. 30µg protein for each sample was loaded per well. Separated proteins were transferred to PVDF membrane and incubated for 1 hour with 5% milk/TBST (w/v) before incubating overnight at 4°C with antibodies against aromatase, TPH-1, BMPR2 and GAPDH (for details of primary antibodies used refer to Supplemental Table 2). Aromatase, TPH-1, BMPR2 and GAPDH molecular weights were detected at 55, 51, 115 and 37 kDa, respectively. Densitometric analysis was performed with TotalLab TL100 software. Data are expressed relative to GAPDH density.

Lung Immunolocalization

Pulmonary vascular aromatase expression was investigated in murine, rat and human lung by immunohistochemistry. Briefly, 5 μm sagittal sections were deparaffinised and rehydrated through a xylene-ethanol gradient. After epitope retrieval, endogenous peroxidase and biotin activity was blocked and lung tissue was incubated for 16 hours with anti-rabbit aromatase antibody or IgG control. 5 μm consecutive sections were also incubated with \pm -smooth muscle actin (\pm -SMA) and von Willebrands factor (vWF) to determine aromatase localisation within the vessel wall. After secondary incubation, aromatase, \pm -SMA and vWF were visualized with the DAB substrate kit (Vector Laboratories, UK), which stained brown/dark brown. In the case of human lung tissue aromatase was visualized with the VIP substrate kit (Vector Laboratories, UK), which stained pink. Images were captured using a Zeiss Axio Imager M1. For details of primary antibodies used refer to Supplemental Table 2.

Human microvascular pulmonary artery endothelial cells (hMPAECs)

(hMPAECs) were grown from surgically discarded lung tissues collected from donors that underwent pulmonary resection for reasons not related to PH (female, 42 year old caucasian) (PromoCell). Cultured PAECs were grown in Endothelial Cell Growth Medium 2 (EGM-2; PromoCell) and utilized for experimental analysis from passage 3–6 inclusive.

hPASCs and PAH-PASCs

hPASCs were provided by Professor N.W. Morrell (University of Cambridge, Cambridge, UK). Briefly, hPASCs were explanted from the distal pulmonary

arteries of macroscopically normal lung tissue at transplantation, with the patient having no reported presence of PAH. PAH-PASMCs were explanted from the distal pulmonary arteries of patients diagnosed with PAH immediately after pneumonectomy. The hPASMCs were isolated from peripheral segments of artery (0.3 to 1.0mm external diameter) by microdissection, as previously described (6). For experiments PASMCs were plated in 10% FBS/DMEM and used between passages 5 to 8. Cultured hPASMCs were confirmed by both staining for α -smooth muscle actin (>97% α -smooth muscle actin-positive cells) and morphological characterization (6). Table E3 describes the clinical characteristics of the human cells and tissues studied.

Figure E1

Systemic arterial blood pressure and heart rate in chronic hypoxic mice model treated with anastrozole. Effects of the aromatase inhibitor, anastrozole (ANA) 0.3 mg⁻¹ kg⁻¹ day⁻¹ and 3 mgkg⁻¹ day⁻¹ for 14 days on **(A)** systemic arterial pressure(mSAP) (n=7-9 per group) and **(B)** heart rate (HR) in female mice (n=7-9 per group); and effects of anastrozole 3 mgkg⁻¹ day⁻¹ for 14 days on **(D)** mSAP (n=6 per group) and **(E)** HR in male mice (n=6 per group). Data displayed as mean ± SEM, analysed by one-way ANOVA with Bonferroni post test.

Figure E2

Estrogen receptor expression is altered in female mouse pulmonary artery in hypoxia. **Female mice:** (A) ER± protein expression and (B) ER² protein expression in normoxic and hypoxic pulmonary arteries from female mice. **Male mice:** (A) ER± protein expression and (B) ER² protein expression in normoxic and hypoxic pulmonary arteries from male mice. Representative immunoblots and graph showing quantification comparing ER± and ER² expression for n=3 pulmonary arteries per group. Data are shown as mean ± SEM and analysed using an unpaired t-test. *p<0.05 vs. Normoxic

Figure E3

MPP 2mgkg⁻¹day⁻¹ attenuates the development of hypoxic pulmonary hypertension in female mice whilst male mice are unaffected. **A-D: female mice.** Right ventricular systolic pressure (RVSP) (A), right ventricular hypertrophy (RV/LV+S) (B) and pulmonary vascular remodelling (C&D) assessment in female mice. **E-H: male mice.** RVSP (E), RV/LV+S (F) and pulmonary vascular remodelling (G&H) are unaffected in males. Representative images of distal pulmonary arteries from each group are shown, (alpha-SMA stains dark brown). Data are expressed as \pm SEM analysed by two-way ANOVA followed by a Bonferroni post-hoc test. * p<0.05; ** p<0.01; *** p<0.001 vs. normoxic; † p<0.05 vs. vehicle. n=6-9 per group. Scale bar (-)=20 μ m.

Figure E4

Effect of aromatase inhibition on cardiac function the female and male Su5416/hypoxia(Su/Hx) rats. **(A)** Cardiac output as determined by echocardiogram on day 14 (D14) and day 28 (D28) following administration of Su/Hx in female rats treated with or without anastrozole (ANA) $0.03 \text{ mgkg}^{-1}\text{day}^{-1}$, $0.3 \text{ mgkg}^{-1}\text{day}^{-1}$ or $3 \text{ mgkg}^{-1}\text{day}^{-1}$ in female rats (n=4-5 per group) and **(B)** Pulmonary artery acceleration time measured serially by echocardiogram at days 0, 14 and 28 in female Su/Hx rats treated with or without anastrozole (n=5 per group). Cardiac parameters were also studied in male Su/Hx rats. **(C)** Cardiac output as determined by echocardiogram on day 14 (D14) and day 28 (D28) following administration of Su/Hx in male rats treated with or without anastrozole $3 \text{ mgkg}^{-1}\text{day}^{-1}$ (n=5 per group) and **(D)** Pulmonary artery acceleration time at days 0, 14 and 28 in male SUGEN/hypoxic rats treated with or without anastrozole (n=5 per group). Data displayed as mean \pm SEM. **p<0.01 as indicated, determined by one-way ANOVA with Dunnett's post test.

Figure E5

Examples of aromatase immunoreactivity in human lung and human microvascular pulmonary artery endothelial cells (hMPAECs). **(A)** Representative image of IgG controls in mouse, rat and human pulmonary artery. **(B)** Representative images showing aromatase immunolocalisation in a pulmonary artery from a female PAH patient (aromatase = pink; \pm -smooth muscle actin (\pm -SMA) = brown; von Willebrand factor (vWF) = brown; scale bar (-) indicates 500 μm). **b** corresponds to patient information in Supplemental Table E3. **(C)** Immunoblot showing absence of aromatase expression in hMPAECs from 4 separate samples. Mouse uterus was used as a positive control for the aromatase antibody.

Figure E6

Effects of aromatase inhibition on hypoxia and Su/Hx-induced changes in Id expression. **A-B: hypoxic mice.** Relative gene expression levels in whole lung of (A) Id1 and (B) Id3 in male and female normoxic and hypoxic mice treated with or without anastrozole (ANA) $3 \text{ mgkg}^{-1}\text{day}^{-1}$ ($n=6$ per group). **D-F: Su/Hx rats.** (C) Id 1 and (D) Id3 relative mRNA levels in female and male normoxic and SUGEN/hypoxic rat lung treated with or without anastrozole $3 \text{ mgkg}^{-1}\text{day}^{-1}$ for 14 days ($n=5-6$ per group). Gene expression levels are normalised to β -2-microglobulin (β 2M). Data displayed as mean \pm SEM. * $p<0.05$ and ** $p<0.01$ as indicated, determined by one-way ANOVA with Bonferroni post test.

Figure E7

Effects of ER \pm antagonist MPP on BMPR2 and Id1 expression in hypoxic female mice. Relative gene expression levels of A BMPR2 and B Id1 in whole lung from female normoxic and hypoxic mice treated with or without MPP $2\text{mgkg}^{-1}\text{day}^{-1}$ ($n=6$ per group). Gene expression levels are normalised to GAPDH). Data displayed as mean \pm SEM. * $p<0.05$ and ** $p<0.01$ as indicated, determined by one-way ANOVA with Bonferroni post test.
