> Framework for Scheduling Problems
> Rámec pro plánování problémy

Description:
Scheduling problems encompass some of the most practical applications in manufacturing systems. A number of scheduling problems exist, including flowshop, jobshop, just-in-time manufacturing etc. This thesis will require the development of a scheduling framework for selected heuristics. The framework will be encompass three unique aspects; constructive heuristics, improvement heuristics and scheduling problems.
The constructive heuristics will be:

1. NEH algorithm (and varients).
2. Local Search (2-OPT).

The improvement heuristics will be:

1. Discrete Artificial Bee Colony (DABC).
2. Chaos driven DABC.

The scheduling problems to be solved would be:

1. Permutative flowshop scheduling.
2. Flowshop scheduling with blocking constraint.
3. Flowshop scheduling with no-wait criterion.

All the constructive and improvement algorithms will be coded for both the CPU and GPU systems. The GPU framework should be developed on the CUDA platform optimized for the Kepler architecture.
The output of the thesis will contain the following:

1. CUDA accelerated constructive and improvement heuristics.
2. Extensive experimentation to show the performance of constructive and improvement heuristics for the different scheduling problems.
3. Analysis on the effect of chaos maps on DABC algorithm.
4. Complex network analysis of Artificial Bee Colony.

Extent and terms of a thesis are specified in directions for its elaboration that are opened to the public on the web sites of the faculty.

Supervisor: doc. MSc. Donald David Davendra, Ph.D.

Date of issue: 01.09.2014
Date of submission: 07.05 .2015

doc. Dr. Ing. Eduard Sojka Head of Department

Dean of Faculty

Prohlašuji, že jsem tuto diplomovou práci vypracovala samostatně. Uvedla jsem všechny literární prameny a publikace, ze kterých jsem čerpala.

V Ostravě 7. Května 2015

I would like to express my gratitude to my supervisor associate professor Donald David Davendra for his useful comments, guidance and support. I would like to thank to my family for their support, namely to my mother Marie Metlická, and my grandmother Marie Hutterová, for their encouragement, and to my father Jaroslav Metlický, for his help with the language.

#### Abstract

Abstrakt Rozvrhovací problémy jsou důležitou podtřídou úloh kombinatorické optimalizace s řadou aplikací ve výrobě a logistice. Většina těchto problémů je NP-úplných (rozhodovací forma) a NP-těžkých (optimalizačń forma), proto se výzkum zamě̌̌uje na návrh efektivních heuristických algoritmů. Dvě hlavní kategorie těchto algoritmů jsou deterministické algoritmy a evoluční metaheuristiky. Deterministické algoritmy zahrnují techniky lokálního prohledávání, například algoritmus k-opt, jejichž cílem je zlepšení existujícího přípustného řešení problému, dále pak konstruktivní heuristiky, jejichž příkladem je algoritmus NEH, které hledané řešení vytvářejí inkrementálně, bez potřeby znalosti vstupního bodu v prohledávaném prostoru řešení. Evoluční metaheuristiky mají za sebou historii úspěšného vývoje v posledních desetiletích, zejména díky jejich efektivitě a flexibilitě. Jejich inspirací jsou poznatky převzaté z biologie, teorie evoluce a inteligence hejna. Mezi nejpopulárnějšími z těchto algoritmů jsou, mimo jiné, genetické algoritmy, diferenciální evoluce, rojení částic (Particle Swarm Optimisation).

Ačkoli tyto heuristiky nalézají ve většině případů řešení blížící se globálnímu optimu v přípustném výpočetním čase, pro řadu aplikací mohou být stále ještě nepřijatelně pomalé. Velké úsilí bylo věnováno zrychlení těchto algoritmů. Protože se vývoj hardware díky dosažení technologických limitů, vzhledem ke zvyšující se spotřebě energie a tepelnému vyzařování, obrací od zvyšování frekvence jednojádrového procesoru k vícejádrovým procesorům a paralelnímu zpracování, je tato snaha většinou orientovaná na paralelizaci existujících algoritmů, aby bylo umožněno využití výpočetní síly vícejádrových platforem (multi-core a many-core). Prvním cílem této práce je tudíž akcelerace dvou deterministických algoritmů, NEH a 2-opt, přičemž bylo dosaženo zajímavých výsledků.

Jiný přístup byl zvolen ve druhé části, s hlavní myšlenkou prozkoumání vlivu náhodnosti na výkon evolučního algoritmu. Za tímto účelem byl zvolen relativně nový a slibný algoritmus Discrete Artificial Bee Colony. Generátor pseudonáhodných čísel byl nahrazen několika různými chaotickými mapami, z nichž některé znatelně zlepšily výsledky algoritmu.

V příspěvcích [27] a [26] bylo ukázáno, že evoluční algoritmy založené na populaci často formují komplexní sítě, vzato z pohledu výměny informací mezi jednotlivými řešeními v populaci během jejího vývoje. Závěrečná část práce aplikuje toto pozorování vložením samo přizpůsobivého mechanismu založeném na analýze komplexní sítě do algoritmu $A B C$, který je evolučním algoritmem pro spojitou optimalizaci a zároveň základem dříve zmíněného $\operatorname{DABC}$ algoritmu. Efektivita několika verzí algoritmu založeném na této myšlence je dokázána na standardní sadě testovacích funkcí pro spojitou optimalizaci. Možnost rozšíření této modifikace na kombinatorické optimalizační problémy je diskutována v závěru práce.

Kličová slova: Plánování, Rozvrhování, Kombinatorická optimalizace, Spojitá optimalizace, Heuristiky, Evoluční algoritmy, Deterministické heuristiky, Flowshop, Flowshop s no-wait omezením, Lot-streaming flowshop, Quadratic Assignment Problem, Capacitated Vehicle Routing Problem, Artificial Bee Colony, Discrete Artificial Bee Colony, NEH, 2-opt, Chaos, Chaotické mapy, Komplexní sítě, CUDA

#### Abstract

Scheduling problems form an important subclass of combinatorial optimisation problems with many applications in manufacturing and logistics. Predominately these problems are NP-complete (decision based) and NP-hard (optimisation based), hence the main course of research in solving them concentrates on the design of efficient heuristic algorithms. Two main categories of these algorithms exist: deterministic algorithms and evolutionary metaheuristics. The deterministic algorithms comprise local improvement techniques, such as k-opt algorithm, which try to improve existing feasible solution, and constructive heuristics, such as NEH, which build a solution starting from scratch, adding one job at a time. Evolutionary metaheuristics have prospered in the past decades, owing to their efficiency and flexibility. Drawing inspiration from the theory of natural evolution or swarm behavioural patterns, the most popular of these algorithms in practice include for instance Genetic Algorithms, Differential Evolution, Particle Swarm Optimisation, amongst others.

However, even though these heuristics provide in most cases close to optimal solution at reasonable execution time, this time is still impractically long for many applications. Therefore much effort has been dedicated to accelerating these algorithms. Since the development of hardware turns away from increasing the clock speed towards the parallel processing units, owing to reaching the limits of technology due to the increased power consumption and heat dissipation, this effort goes into parallelisation of the existing algorithms, to enable exploitation of the computing power of multi-core or many-core platforms. This is the goal of the first part of the thesis, accelerating two of the deterministic algorithms, NEH and 2-opt, with interesting results.

Another approach has been taken in the second part, with the core premise of exploring the influence of stochasticity on the performance of an evolutionary algorithm, selecting the relatively recent and promising Discrete Artificial Bee Colony algorithm. The pseudo-random number generator has been replaced with the different types of dissipative chaos maps, with some of them improving the algorithm significantly.

It has been shown in [27] and [26], that the population based evolutionary algorithms often form complex networks, taken from the point of view of the information exchange between individual solutions during the course of population development. The final part of this thesis puts this observation into practice by embedding the complex network

analysis based self-adaptive mechanism into the ABC algorithm, a continuous optimisation problems solving evolutionary algorithm, which is however the basis for the afore mentioned DABC algorithm, and proving the effectiveness for some of the developed versions, currently on the standard continuous optimisation test functions, with the possibility to extend this modification to the combinatorial optimisations problems in the future being discussed in the conclusion.

## 1 Introduction

Scheduling is an everyday term, which infers on the arrangement of some process, task or resources. These are generally referred to as schedules, which can be defined as a tangible plan or document. A schedule is this sense can range from a bus timetable to a flight schedule.

A structured schedule is an integral part of any engineering or manufacturing process. The main emphasis therefore from the engineering point of view is knowing the type and the amount of each resource so that we can determine when the tasks can feasibly be accomplished. The resource in this way define the schedule boundaries, therefore leading to a bounded solution space. Once the resources have been defined, it becomes imperative to describe the tasks in terms of resource requirements, duration and start time.

Scheduling theory deals with mathematical models that relate to the process of scheduling. This is considered a quantitative approach, where the problem structure is converted into a mathematical form. The main emphasis is then to translate the description of resources and tasks to an explicit objective function [5].

The objective function of any scheduling system relies on three facets; turnaround, which measures the time required to complete the task, timeliness, which measures the conformance of a particular task's completion to a given deadline and throughput, which measures the amount of work completed during a fixed period of time.

A particular solution to a scheduling problem has to take into consideration two issues [5]:

1. resource allocation for a particular task
2. allocation of particular task

If the resources are available at the beginning of the task, the schedule is considered deterministic. If the resources become available over time during the task, the system is then considered stochastic.

A number of different models exist which solve scheduling problems. These can be divided into two categories: deterministic and heuristic models.

### 1.1 Deterministic Algorithms

Deterministic models have been around since the mid 1940's, when the advent of World War 2, led to the establishment of the operations research discipline, in order to conserve and carefully utilise dwindling resources. Some of the most widely used models can be classified as the following:

1. Linear Programming (LP) model [100]
2. Simplex Model [19]
3. NEH Algorithm [76]
4. Lin-Kernighan algorithm (k-opt) [104]

The LP model is the most widely used general scale model. Its corresponding discrete counterpart is the Integer Programming (IP) model or the Integer Linear Programming (ILP) model. The LP model is constructed using three basic elements:

1. Decision variables: which represents (unknown) decisions to be made, which is in contrast to the problem data, which is precise.
2. Objective: which has to be linear on the decision variables, implying that it is the sum of constraints times the decision variables.
3. Constraints: which limit feasible decisions.

Using the above three elements, the final model of a problem can be constructed. This model can be solved using a number of different approaches, such the algebraic, graphical or simplex method.

The simplex method is one the most powerful approaches to solve a LP model. Using the standard form of LP model, a simplex tableaux can be constructed. By generating a basic feasible solution, repeated iterations can be conducted on the tableaux in order to find the optimal value of the entering variables. For full description of the simplex algorithm, the reader is referred to [19]. Many different approaches of simplex exists, including the revised simplex algorithm.

Whereas, simplex uses a basic feasible solution to start its iterations, the NEH (Nawaz, Ensore and Ham) algorithm aims to construct a near optimal solution. The NEH model relies on two preconditions; that the resources are available at the start and the processors are preemptive. The principle of NEH is quite simple:

1. Compute the completion time of all tasks using the resources.
2. Sort the tasks in ascending order based on the completion time.
3. Take the first two tasks and sort them to satisfy the objective function.
4. Likewise take each subsequent remaining task and sort it with the partial completed task list until all tasks are hence scheduled.

The NEH algorithm is widely considered the highest performing method in manufacturing scheduling and is an inherent component of almost all major scheduling systems [95].

The Lin-Kernighan algorithm on the other hand tries to exploit the neighbourhood of a schedule in order to improve it. The precondition of this algorithm is that the schedule must be complete. The steps can be given as:

1. Take the first task and swap it with the adjacent task.
2. Evaluate the new schedule.
3. If the objective function is improved, then retain the new schedule.
4. Iterate for all subsequent tasks in the schedule.

A number of variants of this algorithms exists, and are generally identified by their complexity. A 2-opt algorithm swaps two tasks in the schedule at one time, and is considered the canonical variant.

### 1.2 Heuristic Algorithms

Since the advent of computing resources, heuristics have come to dominate many engineering applications. Some of the first constructive heuristics to be successfully applied to scheduling problems were:

- Tabu Search [16]
- Simulated Annealing [54]

In the late 1990's however, meta-heuristics based on evolutionary paradigms started to appear. Algorithms based on naturally occurring phenomena, such as human genetics, population demographics, swarm behaviour and patterns started to evolve and have become the most dominant paradigms within the last decade. Some of the most common ones are:

- Genetic Algorithms [93]
- Differential Evolution [33]
- Particle Swarm Optimisation [112]
- Self-Organising Migrating Algorithm [17]
- Harmony Search Algorithm [86]
- Artificial Bee Algorithm [48]
- Firefly Algorithm [31]
- Bat Algorithm [124]

### 1.3 Scheduling framework

As scheduling covers such a broad and diverse field of applications, this thesis is concentrated on three main classes of manufacturing, routing and assignment problems.

Manufacturing scheduling is concerned with the manufacturing process, where jobs are generally scheduled to machines in order to reduce the total completion time (makespan) or to minimise delay (tardiness).

A general manufacturing environment is generally refereed to as a shop and the formulation of the process; the way in which the jobs are completed is referred to as its
complexity. Generally, all such environments can be contrived as strictly permutative and are hence therefore as least NP Complete [88].

The three manufacturing problems solved in this thesis are the permutative flowshop scheduling (FSS) problem, the flowshop with no wait (FSSNW) problem and the lot streaming flowshop (FSSLS) problem.

Routing problems have gained importance in fleet scheduling, airport routing and delivery scheduling amongst others. The capacitated vehicle routing problem (CVPR) [115] is where a fixed fleet of delivery vehicles of uniform capacity must service known customer demands for a single commodity from a common depot at minimum transit cost.

The quadratic assignment problem (QAP) generally deals with two counterparts; facilities and its locations. As there is a natural flow between these facilities, the objective is then to assign all facilities to different locations in such a way as to minimize the sum of the distances multiplied by the corresponding flows.

The main meta-heuristic used in this thesis is the Artificial Bee Colony (ABC) [47] and its discrete variant Discrete Artificial Bee Colony (DABC) [114]. This algorithm was selected as it is one of the most recent and promising algorithms, with a wide array of procedures, which in turn makes it quite versatile in solving scheduling problems. The main aim has been to modify and improve this heuristic.

To archive this aim, two separate experimentations were conducted, one on chaos based stochasticity and the other on complex network analysis. In regards to complex network analysis, the initial development was conducted on the canonical ABC algorithm. In order to test this algorithm and its self adaptive features, unimodal and multimodal real-domain problems were tested, and thereby included in this thesis.

The framework consists of three unique aspects.
GPU Acceleration : the first aspect of the thesis is the acceleration of the NEH and 2-Opt local search algorithms. As both these deterministic algorithms have proven to be time demanding, CUDA based GPU accelerated variants have been developed and tested on standard test sets.

Chaos stochasticity : Unique chaotic maps have been added to the DABC algorithm to gauge its effectiveness and analyse the influence of stochasticity.

Complex Network Analysis : A self-adaptive islands model based ABC algorithm is developed, where complex network properties, especially centralities are measured during evolutions. These measures are then used to develop self-adaptive mechanism to steer the population development.
The description of the experimentations is given in Table 1.
The thesis outline is as follows. Chapter 2 gives the theoretical background of different evolutionary algorithms, different chaos maps, description of complex network analysis, an overall introduction to high performance computing and CUDA and the test problem formulation.

Chapter 3 gives the detailed description of all the improvements and implementation of the algorithms. Section 3.1 outlines the CUDA accelerated NEH algorithm and section

Table 1: Outline

| Paradigm | Heuristic | Problem |
| :--- | :--- | :--- |
| CUDA (GPU) | NEH | FSS[73] |
|  | 2-Opt | FSS |
| Chaos maps | Discrete Artificial Bee Colony | FSSNW[74] |
|  |  | FSSLS[71] |
|  |  | QAP[75] |
|  |  | CVRP[75] |
| Complex Network | Artificial Bee Colony | Standard test functions[72] |

3.2 describes the CUDA based 2-opt local search. The chaos based DABC algorithm is described in 3.3. The final component of complex network embedded ABC algorithm is given in section 3.4.

All experimentation and results is given in Chapter 4, with the CUDA accelerated NEH given in section 4.1 and 2-opt local search in section 4.2. The four experimentations of chaos induced DABC algorithm is given as follows: FSSLS in section 4.3, FSSNW in section 4.4, QAP in section 4.5 and CVRP in section 4.6. The results for the complex network analysis is given in section 4.7.

The analysis of the experimentations is given in Chapter 5 and follows the same trend as the experimentation section. CUDA accelerated NEH is analysed in section 5.1 and 2opt local search in section 5.2. The experiments for the CDABC algorithm is analysed in section 5.3 for the FSSLS problem, section 5.4 for the FSSNW problem, section 5.5 for the QAP problem and section 5.6 for the CVRP problem. The analysis of complex network is given in section 5.7.

The thesis is finally concluded in Chapter 6.

## 2 Theory

### 2.1 Evolutionary Algorithms and Heuristics

In the following sections the overview of heuristics and evolutionary algorithms used in this research is presented. For the first part of the thesis, which is the acceleration of the selected heuristics used in scheduling problems, the NEH algorithm is described in Section 2.2, and the 2-opt algorithm in Section 2.3. The second part concentrates on the enhancement of an evolutionary algorithm applied to the scheduling problem by employing chaos pseudo-random number generator in place of standard pseudo-random number generators. The evolutionary algorithm chosen for this purpose was the efficient population based metaheuristic specifically developed for the solution of combinatorial optimisation problems, the DABC algorithm, hence its description is presented in Section 2.5. Finally for the last part, an evolutionary algorithm was enhanced with the complex network analysis based self-adaptive control. For this research, the original ABC algorithm for continuous optimisation, a basis for the later developed DABC algorithm, was used. Therefore, the ABC algorithm description is presented in Section 2.4. Because the DABC was created as a modification to the original continuous optimisation technique $A B C$ and uses the same basic structure, the description of $A B C$ algorithm precedes the $D A B C$ in the text.

### 2.2 NEH Algorithm

The NEH algorithm can be described as follows. Assume that $p_{i, j}$ can be considered as the processing time of job $j$ on machine $M_{i}$, where $i=1,2, \ldots, m$ and $j=1,2, \ldots, n$. The objective is to minimise the makespan, which can be represented as the length of a critical path in an acyclic network.

NEH can be described by the following steps:
Step 1: Arrange the jobs by decreasing sums of their total processing times $T_{k}=\sum_{i=1}^{m} p_{i, k}$.
Step 2: Take the first two jobs, find their order with the shorter makespan, and set $L=3$.
Step 3: Assume that the current subsequence is $\left(j_{1}, j_{2}, \ldots, j_{L-1}\right)$. Find the one with the shortest makespan in $\left(r, j_{1}, j_{2}, \ldots, j_{L-1}\right),\left(j_{1}, r, j_{2}, \ldots, j_{L-1}\right), \ldots$,
$\left(j_{1}, j_{2}, \ldots, j_{L-1}, r\right)$
Step 4: Set $L=: L+1$. If $L=n+1$, then stop; otherwise return to Step 3 .
The general complexity of NEH can be given as $O\left(m n^{2}\right)$ [46].

### 2.3 2-opt Algorithm

The 2-opt algorithm is one of the most famous heuristics developed originally for solving the TSP problem. It was first proposed by Croes [15]. Along with 3-opt, generalized as k-
opt [62], these heuristics are based on exchange of up to $k$ edges in a TSP tour (more information on application of k-opt local search techniques to TSP and CRP problems can be obtained from [99]). Together they are called exchange or local improvement heuristics. The exchange is considered to be a single move, from this point of view, such heuristics search the neighbourhood of the current solution, i.e. perform a local search and provide a locally optimal solution (k-optimal) to the problem [45].

The 2-opt procedure requires a starting feasible solution. It then proceeds by replacing the two non-adjacent edges, $\left(v_{i}, v_{i+}\right)$ and $\left(v_{j}, v_{j+}\right)$ by $\left(v_{i}, v_{j}\right)$ and $\left(v_{i+}, v_{j+}\right)$, and reversing one of the subpaths produced by dropping of edges, in order to maintain the consistent orientation of the tour. For example, the subpath $\left(v_{i}, v_{i+}, \ldots, v_{j}, v_{j+}\right)$ is replaced by $\left(v_{i}, v_{j}, \ldots, v_{i+}, v_{j+}\right)$. The solution cost change produced in this way can be expressed as $\Delta_{i j}=c\left(v_{i}, v_{j}\right)+c\left(v_{i+}, v_{j+}\right)-c\left(v_{i}, v_{i+}\right)-c\left(v_{j}, v_{j+}\right)$. If $\Delta_{i j}<0$, the solution produced by the move improves upon its predecessor. The procedure iterates until no move where $\Delta_{i j}<0$ (no improving move) can be found [38].

In the scheduling problem, the 2-opt move constitutes of exchanging two jobs of the schedule.

The 2-opt local search was described by Kim, Shim and Zhang [52] as follows:
Step 1: Let $S$ be the initial solution, $f(S)$ its objective function value. Set $S^{*}=S, i=$ $1, j=i+1=2$.

Step 2: Consider exchange result $S^{\prime}$ such that $f\left(S^{\prime}\right)<f\left(S^{*}\right)$. Set $S^{*}=S^{\prime}$. if $j<n$ repeat step 2. Otherwise set $i=i+1$ and $j=i+1$. if $i<n$ repeat step 2 , otherwise go to step 3.

Step 3: if $S \neq S^{*}$ set $S=S^{*}, i=1, j=i+1$ and go to step 2. Otherwise output best solution $S$ and terminate the process

### 2.4 Artificial Bee Algorithm

The ABC algorithm was originally developed by Karaboga [48], for the purpose of multivariable multi-modal continuous functions optimisation. Since then, many variations to the original ABC algorithm were created and employed in solving different types of problems (constrained optimisation [49], multi-objective optimisation [60], combinatorial optimisation ([40], [43], [85], [113])).

In the classification of optimisation heuristics, the Artificial Bee Colony belongs to the group of population, swarm intelligence based stochastic algorithms. Along with other algorithms of this category (such as ACO [29], PSO [51], SOMA ([129],[24]) or Artificial Immune Algorithm (AIA) [4]), ABC searches for optimal solution employing certain number of intelligent agents, who search independently, but also share the information on the system, in order to achieve more efficient behaviour. Amongst the advantages of such approach is inherent parallelism and scalability - it is possible to assign different subgroups of agents to different computational resources.

### 2.4.1 Description

As well as many other population based metaheuristics, $A B C$ takes inspiration from nature. Namely, from the intelligent behaviour of foraging honey bee swarm. From this inspiration stems also the nomenclature. Several solutions, called food sources, form the population. These solutions are exploited by employed bees. Each employed bee tries to improve one solution at a time (which symbolises extracting a nectar from a food source). Onlooker bees are waiting in the hive to make a decision where to look for a food source. When employed bee arrives, it performs a specific dance, which points the onlooker bee to the direction of a food source. The onlooker bee then determines, based on observation of returning employed bees, where to go. The algorithm emulates this by evaluating the cost function for each solution generated by employed bee. The onlookers choose a solution to improve, based on probability given by relative amount of nectar (cost function value relative to sum of all solutions costs). Finally, if the food source has been exhausted, a scout bee will try to find a new one, unrelated to the previous. Both employed bees and onlooker bees perform exploitation, whereas scout bees responsibility is the exploration of solutions space [47].

The overall algorithm therefore consists of initialisation of population, and three phases performed in succession iteratively, until the predefined terminating criterion is met: employed bee phase, onlooker bee phase, and eventually scout bee phase, as outlined above. The top-level pseudocode of ABC is given in Algorithm 1.

```
initialize
repeat
    send employed bees to food sources
    send onlooker bees to selected food sources
    send scout bees to search for new food sources
    memorize best solution
until terminating criterion met
```

Algorithm 1: ABC top-level pseudocode
The solution in continuous space is represented as a numerical vector of dimension $D$, whose elements are values of optimised parameters. The population is formed by $F S$ such solutions. The quantity associated with each solution, before it is considered exhausted (a number of trials for bees to try and improve the solution) is called limit. Limit, FS and terminating criterion are the only controlling parameters of the ABC algorithm. Dimension $D$ is given by a definition of optimised function.

### 2.4.2 Initialisation

Unless some preliminary information on the system is available, the population of solutions is initialised randomly as follows:

$$
\begin{equation*}
\mathbf{x}_{i, j}=L_{j}+\left(U_{j}-L_{j}\right) \cdot r \tag{1}
\end{equation*}
$$

Where $\mathbf{x}_{i, j}$ denotes $j$-th element of $i$-th vector, $j \in\{1,2, \ldots, D\}, i \in\{1,2, \ldots, F S\} . L_{j}$ and $U_{j}$ is lower, respective upper bound of $j$-th dimension of the search space (minimal, respective maximal value allowed for the $j$-th element of a vector), and $r$ represents a random number in range $[0,1]$.

### 2.4.3 Employed bee phase

In employed bee phase, as mentioned earlier, each employed bee $i$ tries to improve a single solution $\mathbf{x}_{i}$, by performing an operation on it, according to Equation (2). The newly created candidate solution $\mathbf{n}_{i}$ is evaluated, and greedy selection is applied - if a solution $\mathbf{n}_{i}$ is better than or equal to previous $\mathbf{x}_{i}$, the previous one is replaced in the population.

$$
\begin{equation*}
\mathbf{n}_{i, j}=\mathbf{x}_{i, j}+\left(\mathbf{x}_{i, j}-\mathbf{x}_{k, j}\right) \cdot \mathbf{r}_{i, j} \tag{2}
\end{equation*}
$$

Where $\mathbf{x}_{i}$ is previous solution in the population, $\mathbf{n}_{i}$ is the candidate solution, $i \in$ $\{1,2, \ldots, F S\}$, index $j$ is randomly chosen in range $[1, D]$, index $k$ is randomly selected from range $[1, F S]$ so that $k \neq i$ and $\mathbf{r}_{i, j}$ is a random number in range $[-1,1]$.

### 2.4.4 Onlooker bee phase

In onlooker bee phase, a selection from all the food sources (solutions) $\left\{\mathbf{s}_{1}, \mathbf{s}_{2}, \ldots, \mathbf{s}_{F S}\right\}$ is performed, based on the probability of each solution, $p_{i}, i \in\{1,2, \ldots, F S\}$, defined in Equation (3). The selected solution is modified using Equation (2) and the greedy selection is again performed between the original and the modified solution, to determine the winning solution to be left in the population, in the same way as described in Section 2.4.3.

$$
\begin{equation*}
p_{i}=\frac{f_{i}}{\sum_{k=1}^{F S} f_{k}} \tag{3}
\end{equation*}
$$

In Equation (3), $p_{i}$ represents probability, $f_{i}$ is fitness of $i-t h$ solution, $i \in\{1,2, \ldots, F S\}$. $F S$ is total number of solutions in the population.

### 2.4.5 Scout bee phase

As mentioned earlier, each solution has a limit of attempts to improve, associated with it. It is being incremented in both employed bee and onlooker bee phase, in case the solution fails to improve (the newly created solution is worse and therefore not selected). If this limit is exceeded, a scout bee generates new, random solution, according to Equation (1), which replaces the exhausted one. In each iteration of the original ABC algorithm, at most one scout bee is released. The increase in the number of scout bees encourages exploration (escaping from local optima and searching in the global space), but also reduces the possibility of exploitation of good solutions already found, since these are removed from the population by this process [48].

### 2.5 Discrete Artificial Bee Algorithm

The DABC algorithm by [113] is a modification to the ABC algorithm for solving combinatorial optimisation problems. As opposed to the continuous optimisation, a solution in combinatorial optimisation is naturally encoded as a permutation of elements. Several approaches are possible for transforming continuous optimisation algorithm for solving combinatorial problems, as described for example in [80].

DABC replaces the neighbourhood generation operation of original ABC by a set of operations which transform one permutation to another, thus completely avoiding generation of infeasible solutions. These operations (4 operations altogether, described in section 2.5.2) are based on swapping two random elements, or inserting an element into permutation.

Each of the operations explores a different type of neighbourhood of a solution, furthermore, each of them is suitable for exploring solution space of different problems. In order to maximally adapt to given problem and explore the neighbourhood in an efficient way, all 4 defined operations are used in an adaptive mechanism. This adaptive strategy, described in section 2.5.3, decides which operation to use, partly depending on the list of previous successful operations (those which produced improved solution), partly randomly.

To enhance the exploitation of solution space, DABC contains embedded local search, described in section 2.5.4.

### 2.5.1 Solution as permutation

As mentioned earlier, a solution is represented as a $D$-dimensional permutation of elements, as shown in Equation (4). The objective of optimisation is to find the least cost permutation. $\pi_{i}$ represents $i$-th solution, $\pi_{i, j}$ the element at $j$-th position in the permutation.

$$
\begin{equation*}
\pi_{i}=\left\{\pi_{i, 1}, \pi_{i, 2}, \ldots, \pi_{i, D}\right\} \tag{4}
\end{equation*}
$$

### 2.5.2 Operations

As mentioned earlier, DABC makes use of 4 operations: Insert, Swap, $2 \times$ Insert, $2 \times$ Swap, defined as follows:

Insert removes a randomly selected permutation element from it's position $j$, reinserts at different randomly selected position $k$ :

$$
\begin{align*}
\pi^{(i)} & =\left(\pi_{1}, \ldots, \pi_{j-1}, \pi_{j}, \pi_{j+1}, \ldots, \pi_{k-1}, \pi_{k}, \pi_{k+1}, \ldots, \pi_{d}\right) \\
\pi^{(i+1)} & =\left(\pi_{1}, \ldots, \pi_{j-1}, \pi_{j+1}, \ldots, \pi_{k-1}, \pi_{k}, \pi_{j}, \pi_{k+1}, \ldots, \pi_{d}\right) \tag{5}
\end{align*}
$$

Swap exchanges 2 different randomly selected elements $j, k$ :

$$
\begin{align*}
\pi^{(i)} & =\left(\pi_{1}, \ldots, \pi_{j-1}, \pi_{j}, \pi_{j+1}, \ldots, \pi_{k-1}, \pi_{k}, \pi_{k+1}, \ldots, \pi_{d}\right) \\
\pi^{(i+1)} & =\left(\pi_{1}, \ldots, \pi_{j-1}, \pi_{k}, \pi_{j+1}, \ldots, \pi_{k-1}, \pi_{j}, \pi_{k+1}, \ldots, \pi_{d}\right) \tag{6}
\end{align*}
$$

$2 \times$ Insert performs 2 successive Insert operations, as defined above. $2 \times$ Swap performs 2 successive Swap operations. Which operation is applied to modify given solution depends on adaptive strategy list.

### 2.5.3 Adaptive Strategy

Adaptive strategy, as described in [113], maintains two lists of operations, behaving like stacks - list of available operations $N L$, and list of previously successful operations $W N L$. On the beginning of the optimisation, the $N L$ is filled with randomly selected operations (4 available operators). Before a solution is modified, operation is taken from the top of $N L$. If the solution improves upon the previous one, the operation is inserted into $W N L$. If a $N L$ is empty, part of it is refilled from operations stored in $W N L$, the rest is refilled again with randomly selected operations. If $W N L$ is empty, the last $N L$ is used again.

### 2.5.4 Local Search

Local search is embedded within DABC. In employed bee phase, after a new successful solution is generated, the local search is performed with probability $P L$, in order to further enhance it. The pseudocode is given in Algorithm 2.

### 2.5.5 Algorithm structure

DABC has similar structure to original ABC algorithm (pseudocode is shown in Algorithm 3). It consists of initialisation, and several iterations of bee phases performed sequentially, until stopping criterion is met. Unless some preliminary information on the problem solution space is known, the population is initialized as a set of random permutations.

### 2.5.6 Parameters

There are 7 control parameters of DABC, 2 of which are only for usage in adaptive strategy. $F S$ is a number of solutions or food sources in the population, and also the number of employed bees and onlooker bees. Limit is a maximum number of unsuccessful trials to improve the solution, before it is abandoned. Loop $\max$ defines a number of iterations in local search, $P L$ is a probability of local search to happen. Stopping criterion in this variant is specified as a number of iterations of DABC algorithm to perform, $T$. The adaptive strategy requires two parameters, $N L_{L}, W N L_{L}$, defining length of $N L$ list and $W N L$ list, respectively [113]. The range and recommended values of parameters are described in Table 2.

```
Input: \(\pi\), fitness, last_operation
begin select operation:
    if last_operation \(\in\{\) insert, \(2 \times\) insert \(\}\) then

    begin 4.memorize best food source:
            \mp@subsup{\pi}{\mathrm{ best }}{}\leftarrow\mp@subsup{\pi}{i}{}\mathrm{ , where: }\forallk,k\not=i:\mp@subsup{\mathrm{ fitness }}{i}{}\mathrm{ better than or equal to fitness }
            fitness best }\leftarrow\mp@subsup{\mathrm{ fitnessi}}{i}{
    end
until stopping criterion met
```

## Algorithm 3: DABC pseudocode

Table 2: Parameter values

| Parameter | Recommended <br> value | Range |
| :--- | :---: | :---: |
| $F S$ | 30 | $[5, \infty]$ |
| Limit | 50 | $[1, \infty]$ |
| Loop $_{\text {max }}$ | 200 | $[1, n]$ |
| $P L$ | 0.2 | $[0,1]$ |
| $T$ | 100 | $[1, n]$ |
| $N L_{L}$ | 20 | $[1, n]$ |
| $W N L_{L}$ | $0.75 N L_{L}$ | $[1, n]$ |

### 2.6 Chaos Systems

The term chaos describes the complex behaviour of simple dynamical systems. When casually observed, this behaviour may seem erratic and somewhat random, however, these systems are deterministic. The precise description of their future behaviour is well known, given by the trajectory on the map. This aperiodic non-repeating behaviour of chaotic systems has opened up the possibility to employ the chaotic sequences in place of pseudo-random sequences, as discussed in Section 2.6.1. Generally, four branches of chaotic systems exist, which are the dissipative systems, fractals, dissipative and highdimensional systems and conservative systems. The systems of interest in this line of research are the discrete dissipative systems. The ones explored in this thesis are introduced in Section 2.6.2.

### 2.6.1 Chaos pseudo-random number generators applied to Evolutionary Algorithms

One of the main pillars of evolutionary algorithms (EA's) is their reliance on randomness or stochasticity, which is used to spark a path towards a desired goal. The current norm is the use of pseudo-random number generators (PRNG); a structured sequence of mathematical formulation which tries to yield a generally optimal distribution of numbers within a specified range. Of these, the Mersenne Twister is the most famous and widely used [70], [69].

Part of this thesis concentrates on the generation of chaotic sequences, which are then used as chaos pseudo-random number generators (CPRNG's) in an EA. The afore introduced properties of the chaotic systems are employed in place of PRNG embedded in an evolutionary algorithm. The objective is to analyse different chaotic systems, which in this case are the discrete dissipative systems, and to find out, which of these improve the application of EA's.

A mathematical description of the connection between chaotic systems and random number generators has been given by [41]. In this paper, a strong linkage has been shown between the Lehmer generator [58] and the simple chaos dynamical system of Bernoulli shift [82]. The hidden periodicity of chaos system and its dependence on numerical system has been shown by [128]. A chaotic piecewise-linear one dimensional (PL1D) map has been utilised as a chaotic random number generator in [106]. The construction of the chaos random number system is based on the exploitation of the double nature of chaos, deterministic in microscopic space and by its defining equations, and random in macroscopic space. This new system is mathematically proven to overcome the major drawbacks of classical random number systems, which are its reliance on the assumed randomness of a physical process, inability to analyse and optimise the random number generator, inability to compute probabilities and entropy of the random number generator, and inconclusiveness of statistical tests. A family of enhanced CPRNG's has been developed by [65], where the main impetus is the generation of very long series of pseudo-random numbers. This is accomplished through what is called the ultra weak coupling of chaotic systems, such as the Tent Map, which is enhanced in order to conceal
the chaotic genuine function [66]. Recently, the very notion of using CPRNG's in EA's has been explored by [127].

Current literature contains a number of research devoted to certainty, ergodicity and the stochastic property of chaotic systems. Recently, chaotic sequences have been adopted instead of random sequences with improved results. The choice of chaotic sequences is justified theoretically by their unpredictability, i.e. by their spread-spectrum characteristics, non-periodic, complex temporal behaviour, and ergodic properties [81].

A number of EA's have been improved using chaos systems as random number generators during the past few years. Genetic Algorithms (GA) have been improved by chaos to solve multi-objective optimisation problems in [118] and [67] and tourism demand forecasting [42], whereas the Firefly algorithm has been embedded with chaos map in [50]. Differential Evolution (DE) has been improved with chaos to solve the support vector regression machine problem [61], dynamic economic dispatch for wind-thermal power systems [87], loudspeaker design problem [13], optimisation of the batch reactor [101], hydrothermal scheduling [126] and PID control problem [25].

The largest group of chaos based literature is on Particle Swarm Optimisation (PSO). Many variants of chaos embedded PSO exist, some of them are novel creations comprising different chaotic approaches in basic PSO design ([123], [92], [102], [90], [1]), accelerated chaos [34] and hybrid approaches [12] amongst others.

Applications of chaos based PSO include pattern synthesis of antenna arrays [119], image matching [64], power system stabiliser design [30], constrained predictive control [44], global numerical optimisation [12], optimisation of heat exchangers [68], reactive power optimisation [59], network intrusion detection [131], PID Controller design [91] and parameters selection [122].

Some of the other algorithm employing chaos are the Discrete Self-Organising Migrating Algorithm (DSOMA) which has been used to solve the lot-streaming problem [23] and a new artificial emotion based chaos algorithm [125].

Part of this thesis describes the application of CPRNGs to the Discrete Artificial Bee Colony algorithm, resulting in chaos driven Discrete Artificial Bee Colony (CDABC) algorithm, introduced in [71], [74] and [75]. This algorithm is described in Section 3.3.

### 2.6.2 Chaos Maps

The most interesting chaotic systems, which can be utilised as CPRNG are discrete dissipative chaotic maps, as stated earlier in the text. These maps have the general description of being a linear set of equations, easily formulated, with a fine grain over the solution landscape. This last attribute allows the parsing of unique values over a period of the chaotic oscillation. In total, nine unique chaotic systems were considered for this experiment. The following sections describe the different systems. All operating parameters were obtained from [105].

Figure 1: Chaotic Burgers map 2D plot

### 2.6.3 Arnold's Cat Map

The Arnold's cat map is a two dimensional discrete chaotic map, which is a torus into itself. The equations are given in (7). The parameter of $k=2.0$.

$$
\begin{align*}
& X_{n+1}=X_{n}+Y_{n} \cdot(\bmod 1)  \tag{7}\\
& Y_{n+1}=X_{n}+k \cdot Y_{n} \cdot(\bmod 1)
\end{align*}
$$

### 2.6.4 Burgers Map

The Burgers mapping is a discretisation of a pair of coupled differential equations which were used by Burgers [10] to illustrate the relevance of the concept of bifurcation to the study of hydrodynamic flows. It has been numerically shown to produce a much richer set of dynamic patterns than those observed in continuous case [120]. The equations are given in Equations (8) and (9).

$$
\begin{gather*}
X_{n+1}=a X_{n}-Y_{n}^{2}  \tag{8}\\
Y_{n+1}=b Y_{n}+X_{n} Y_{n} \tag{9}
\end{gather*}
$$

The operating parameters are $a=0.75$ and $b=1.75$ with the initial conditions being $X_{0}=-0.1$ and $Y_{0}=0.1$. As in the previous cases the frequency plot of the real and integer values is given in Figure 2, whereas the $x$ and $y$ values plots are given in Figure 3.

Figure 2: Histogram of the distribution of real numbers transferred into the range $\langle 0,1\rangle$ and integer numbers in the range $\langle 1,25\rangle$ generated by means of the chaotic Burgers map, 5000 samples.

Figure 3: Iteration of the Burgers map for the $x$ and $y$ values in point-plot

### 2.6.5 Delayed Logistic

The Delayed Logistic map is a dissipative map with a smooth invariant circle interspersed among parameter intervals for which the attractor appears to be strange [3]. This phenomena has given rise to its application in population growth models. The equations of the Delayed Logistic are given in Equations (10) and (11).

$$
\begin{gather*}
X_{n+1}=A X_{n}\left(1-Y_{n}\right)  \tag{10}\\
Y_{n+1}=X_{n} \tag{11}
\end{gather*}
$$

The operating parameters are $A=2.27$ and the initial conditions are $X_{0}=0.001$ and $Y_{0}=0.001$. The real and integer values histogram in given in Figure 5, and the $x$ and $y$ values plots in Figure 6.

Figure 6: Iteration of the Delayed Logistic map for the $x$ and $y$ values in line-plots

### 2.6.6 Dissipative Standard Map

The Dissipative Standard Map is a two-dimensional chaotic system. The equation is given in (12) and the operating parameters are $\beta=0.1$ and $k=8.8$.

$$
\begin{align*}
& X_{n+1}=X_{n}+Y_{n-1} \cdot(\bmod 2 \pi) \\
& Y_{n+1}=\left(\beta \cdot Y_{n}\right)+\left(k \cdot \sin X_{n}(\bmod 2 \pi)\right) \tag{12}
\end{align*}
$$

### 2.6.7 Henon Map

The Henon map is a discrete-time dynamical system, which was introduced as a simplified model of the Poincare map for the Lorenz system. The equation is given in (13) and the control parameters are $\alpha=1.4$ and $\beta=0.3$.

$$
\begin{align*}
& X_{n+1}=\alpha-X_{n}^{2}+\left(\beta \cdot Y_{n}\right) \\
& Y_{n+1}=X_{n} \tag{13}
\end{align*}
$$

### 2.6.8 Ikeda Map

The Ikeda map is a discrete-time dynamical system derived as a model of light going around across a nonlinear optical resonator. A 2D real example of the Ikeda map is given in equation (14). The operating parameters are $\alpha=0.75, \beta=1.75, \gamma=1$ and $\mu=0.9$.

$$
\begin{align*}
& X_{n+1}=\gamma+\mu \cdot\left(\left(X_{n} \cdot \cos \phi\right)-\left(Y_{n} \cdot \sin \phi\right)\right) \\
& Y_{n+1}=\mu \cdot\left(\left(X_{n} \cdot \sin \phi\right)+\left(Y_{n} \cdot \cos \phi\right)\right)  \tag{14}\\
& \phi=\beta-\frac{\alpha}{\left(1+X_{n}^{2}+Y_{n}^{2}\right)}
\end{align*}
$$

### 2.6.9 Lozi Map

The Lozi map is a two-dimensional piecewise linear map whose dynamics are similar to those of the better known Henon map and it admits strange attractors.

The advantage of the Lozi map is that one can compute every relevant parameter exactly, due to the linearity of the map, and the successful control can be demonstrated rigorously.

The Lozi map equations are given in Equations (15) and (16).

$$
\begin{gather*}
X_{n+1}=1-a\left|X_{n}\right|+b Y_{n}  \tag{15}\\
Y_{n+1}=X_{n} \tag{16}
\end{gather*}
$$

The parameters used are $a=1.7$ and $b=0.5$ as suggested in [105] and the initial conditions are $X_{0}=-0.1$ and $Y_{0}=0.1$. The real number and integer number plots for a sample iteration is given in Figure 8 and the $x$ and $y$ value 2D plots is given in Figure 9. The figures presented of the chaotic maps are referenced from [103].

Figure 7: Chaotic Lozi map 2D plot

Figure 8: Histogram of the distribution of real numbers transferred into the range $\langle 0,1\rangle$ and integer numbers in the range $\langle 1,25\rangle$ generated by means of the chaotic Lozi map, 5000 samples.

Figure 9: Iteration of the Lozi map for the $x$ and $y$ values in line-plot.

### 2.6.10 Sinai Map

The Sinai map is a simple two-dimensional discrete system similar to the Arnold's Cat map. The equation is given in (17) and the control parameter is $\delta=0.1$.

$$
\begin{align*}
& X_{n+1}=X_{n}+Y_{n}+\left(\delta \cdot \cos 2 \pi \cdot Y_{n} \cdot(\bmod 1)\right) \\
& Y_{n+1}=X_{n}+2 \cdot Y_{n} \cdot(\bmod 1) \tag{17}
\end{align*}
$$

### 2.6.11 Tinkerbell Map

The Tinkerbell is yet another Dissipative map, which has been proven to be chaotic [2] and studied extensively for its unique chaotic attractor. The equations of the Tinkerbell is given in Equations (18) and (19).

$$
\begin{gather*}
X_{n+1}=X_{n}^{2}-Y_{n}^{2}+a X_{n}+b Y_{n}  \tag{18}\\
Y_{n+1}=2 X_{n} Y_{n}+c X_{n}+d Y_{n} \tag{19}
\end{gather*}
$$

The usual operating parameters for Tinkerbell are $a=0.9, b=-0.6, c=2$ and $d=0.5$. The initial conditions are $X_{0}=0$ and $Y_{0}=0.5$. The real and integer frequency plots are given in Figure 11, whereas the $x$ and $y$ values are given in Figure 12.

Figure 10: Chaotic Tinkerbell map 2D plot

### 2.7 Complex Networks

Many real world systems, both man-made and natural, form a network. Amongst many examples are the communication systems (Internet, World-wide web), transportation systems, neural networks, or protein interaction networks, social interaction structures (social networks), etc. These networks are often too large to describe completely, hence the local description is used instead, using probabilistic expression of the local properties in place of the exact ones, considering the random graphs [8],[116].

### 2.7.1 Complex Network Analysis

Many evolutionary algorithms based on the population of solutions form a complex network in terms of exchange of information amongst the individuals throughout the search for the optimum. As an example, SOMA [27] and DE [26] were analysed from this point of view, and proven to form the complex network in the course of the algorithm iterations. In this work, the information flow amongst the solutions of the population in the $A B C$ algorithm is explored, and the knowledge of the complex network structure and properties is subsequently used to moderate the search.

The ABC forms a complex network during the course of the iterations, which was empirically validated. This complex network was recorded as a weighted adjacency matrix, representing the directed graph, where the vertices represent the individuals, while oriented edges stand for the information flow between them, with weights representing the number of successful improvements of the target individual using the information from the source individual.

The complex network structure can be analysed by many different techniques and measures. In order to measure the influence and importance of the individual nodes to the whole network, the centrality of the vertices was chosen as a natural way to accomplish this goal.

### 2.7.2 Centrality

Centrality of vertices is a means of analysis of complex network by identifying the most important or influential nodes in the graph. Several centrality measures exist, the most common being the Degree centrality, Closeness and Betweenness, which measure the direct connections of the node, accessibility of the node and how much the node is intermediary between other nodes, respectively.

Degree Centrality Degree centrality of the node is the number of the edges incident with the node. For a directed graph, the number of only incoming (in-degree), outgoing (out-degree) or both edge types can be considered. In a weighted network, the degree of the node has been extended as a sum of the incident edges weights. The degree centrality
measures the local connections of the node. The unweighted degree centrality of node $i$ is defined as follows:

$$
\begin{equation*}
C_{D}(i)=\sum_{j=1}^{n} a_{i j} \tag{20}
\end{equation*}
$$

Where $n$ is the total number of nodes, $a_{i j}$ is 1 if an edge exists between nodes $i$ and $j$, 0 if it doesn't exist [117].

Weighted degree centrality (strength) of node $i$ :

$$
\begin{equation*}
C_{S}(i)=\sum_{j=1}^{n} a_{i j} w_{i j} \tag{21}
\end{equation*}
$$

The meaning of $n$ and $a_{i j}$ is the same as for the unweighted degree, $w$ is weight of the edge between $i$ and $j$ [8].

Closeness Centrality The closeness of a node measures it's accessibility - how close the node is along the shortest path to all the other nodes, on average. It is defined as the inverse of the average shortest distance from the node to all other nodes. The following equation defines the closeness centrality of the node $i$ :

$$
\begin{equation*}
C_{C}(i)=\frac{n-1}{\sum_{j \in\{1 . . N\}, j \neq i} d_{i j}} \tag{22}
\end{equation*}
$$

Where $d_{i j}$ is the shortest path between $i$ and $j$ [117].
Betweenness Centrality The betweenness measures how much the node lies between other nodes in the network. The nodes with high betweenness centrality are likely to serve as mediators in information exchange between other nodes, and therefore can be seen as more important. The betweenness of a node is a ratio of the shortest paths between other node pairs passing through the node. Betweenness centrality of node $i$ is given by the following equation:

$$
\begin{equation*}
C_{B}(i)=\sum_{k, j \in\{1 . . N\}, k \neq j \neq i} \frac{\sigma_{k, j}(i)}{\sigma_{k, j}} \tag{23}
\end{equation*}
$$

Where $\sigma_{k, j}$ is the number of the shortest paths between $k$ and $j$, and $\sigma_{k, j}(i)$ is the number of shortest paths between $k$ and $j$ that pass through $i$ [117].

### 2.8 CUDA

The GPGPU (general purpose GPU computing) has been in the focus of many researches ever since the GPUs performance rapid increase, owing to the increasing demand for powerful hardware capable of rendering ever more demanding game graphics, along with the increasing programmability of the GPU. However, the first GPU really supporting scientific computations was developed several years later in 2006 by NVIDIA, whose architecture CUDA (Compute Unified Device Architecture) eventually enabled programming GPUs by means of small set of extensions to C/C++ language, as opposed to former necessity of using graphic programming languages and primitives ([97], [53])

As mentioned earlier, CUDA-enabled GPUs are programmed using extensions to C/C++ language, CUDA C language. Furthermore, several different languages, APIs or CUDA accelerated libraries are supported. CUDA programming model is data parallel and widely scalable. The computational task is divided between multicore CPU and manycore GPU with separate memory spaces and different properties, strengths and weaknesses - so called heterogenous programming. Compute intensive data parallel tasks are offloaded to the GPU, while tasks requiring sophisticated flow control are executed sequentially on the CPU.

At the heart of CUDA programming model are three key abstractions: thread hierarchy, memory hierarchy and synchronization, providing coarse grained parallelism (blocks in grid), and fine grained parallelism (threads in block, which can communicate and be synchronized).

Thread hierarchy The data parallel task is implemented using special function called kernel, whose code is executed in parallel by threads. Threads are organized into blocks, blocks of threads are organized into grids. Whereas threads in each block can communicate by means of shared memory and synchronization function, threads between different blocks are completely independent of one another. Each thread within block, as well as each block within grid, is distinguishable by threadId, respectively blockId. This enables each particular thread to operate on different data element in the global memory.

Memory hierarchy CUDA application can make use of different memory types. Memories differ in size and speed, as well as supported effective access patterns. Some of them are cached, some are read-only. The design of effective memory usage is one of the key issues of CUDA program performance. So called global memory is shared by all blocks, as well as between successive kernel calls, and is relatively slow. Much faster shared memory is accessible by all threads within one block. The fastest register memory is used to store local variables for one thread, which are not visible to any other thread. However, for big data structures or if the total amount of memory needed for local variables by all threads within block exceeds the registers capacity, the slower local memory must be used. Constant memory can be employed to store data that will not be changed by the kernel code, especially when all threads access the same data element at a time. The texture memory is a read-only cache that provides a speed-up for locality in data access by threads [78].

Synchronization As mentioned earlier, blocks in grid provide for coarse grained parallelism, whereas threads in block provide for fine grained parallelism. Threads in a block can be synchronized and share data in the scope of a kernel. The number of threads in a block is however limited both by the CUDA GPU design (max. 1024), and by the memory resources consumed by each thread. This division permits scalability - the blocks are scheduled independently of one another, each of them assigned to one of the GPU's multiprocessors ([77], [78]).

### 2.9 Combinatorial Optimisation and Scheduling Problems

This section gives the overview of the theory and formulation of the problems to which the combinatorial optimisation methods explored in this thesis have been applied. The combinatorial optimisation is the subset of optimisation problems, generally formulated, where an optimal solution from the finite set of feasible solutions is sought after. They can be defined as seeking a subset $S^{*} \in \mathbf{S}$, given the collection $\mathbf{S} \subseteq 2^{E}$ on some finite ground set $E$; and $c: \mathbf{S} \rightarrow \mathbb{R}$; such that $S^{*}$ maximizes or minimizes $c$ on $\mathbf{S}$ [28].

The problems of interest from the combinatorial optimisation field are the NP-hard problems where the exhaustive search methods are infeasible. Of this category, the quadratic assignment problem and capacitated vehicle routing problem are presented later in the text, in Sections 2.9.1 and 2.9.2.

The special consideration is given to the scheduling problems. The scheduling as a process of decision making is used on daily basis in manufacturing and production systems and service industries. The scheduling problems in general deal with the task of sequencing a collection of jobs in certain machine environment, subject to given constraints, in such a way that one or more performance criteria are optimised. Of the two broad classes of scheduling models, the deterministic and stochastic scheduling, the deterministic model is considered, with the finite collection of jobs to be scheduled, where the exact job data are known in advance. The following text describes the lot streaming flow shop with setup times (Section 2.9.5), permutative flow shop and the flow shop with no-wait constraint (Sections 2.9.3 and 2.9.4) [89].

### 2.9.1 Quadratic Assignment Problem

The quadratic assignment problem (QAP) is a combinatorial optimisation problem stated for the first time by [55] and is widely regarded as one of the most difficult problems in this class. The objective is to assign $\boldsymbol{n}$ facilities to $\boldsymbol{n}$ locations in such a way as to minimise the assignment cost.

The assignment cost is the sum, over all pairs, of the flow between a pair of facilities multiplied by the distance between their assigned locations.

Let $C$ and $D$ be two $n \times n$ matrices such that $C=\left[c_{i, j}\right]$ and $D=\left[d_{i, j}\right]$. Consider the set of positive integers $\{1,2, \ldots, n\}$, and let $S_{n}$ be the set of permutations of $\{1,2, \ldots, n\}$. Then the quadratic assignment problem can be defined as follows:

$$
\begin{equation*}
\min \sum_{i=1}^{n} \sum_{j=1}^{n} c_{i, j} d_{\pi(i) \pi(j)} \tag{24}
\end{equation*}
$$

over all permutations $\pi \in S_{n}$. The above formulation is known as the KoopmansBeckman QAP [55].

Stated in other words, the objective of the quadratic assignment problem with cost matrix $C$ and distance matrix $D$ is to find the permutation $\pi_{0} \in S_{n}$ that minimises the double summation over all $i, j$.

It should be understood that the notation $d_{\pi(i) \pi(j)}$ as used above, refers to permuting the rows and columns of the matrix $D$ by some permutation $\pi$.

That is, $D^{\pi}=\left[d^{\pi}{ }_{i, j}\right]=d_{\pi(i) \pi(j)}$, for $1 \leqslant i, j \leqslant n$. In the same manner, given an $n$ dimensional vector $V=\left[v_{i}\right]$, a permutation of the elements of $V$ by a permutation $\pi$ will be denoted as $V^{\pi}=\left[v^{\pi_{i}}\right]=v_{\pi(i)}$.

A number of heuristics have been developed to handle large scale QAP problems; some notable ones being simulated annealing [14], tabu search [107] and the hybrid genetic-tabu search [32].

### 2.9.2 Capacitated Vehicle Routing Problem

The vehicle routing problem is a well known problem in the field of transportation ([18], [57], [115], [6], [36], [7]). The basics of capacitated vehicle routing problem can be stated as follows [63]. Each vehicle has the same loading capacity, and starts off from only one delivery depot and then routes through customers. All customers have known demands and required service time. Each customer can only be visited by one vehicle, and each vehicle has to return to the depot. The service time unit can be transformed into the distance unit. The loading and traveling distance of each vehicle cannot exceed the loading capacity and the maximum traveling distance of vehicle. The objective of CVRP is to minimize the traveling cost. The capacitated vehicle routing problem can be modeled as a mixed integer programming as follows:

$$
\begin{equation*}
\min \sum_{i=0}^{N} \sum_{j=0}^{N} \sum_{K=1}^{K} C_{i j} X_{i j}^{k} \tag{25}
\end{equation*}
$$

Subject to:

$$
\begin{gather*}
\sum_{i=0}^{N} \sum_{j=0}^{N} X_{i j}^{k} d_{i} \leq Q^{k} \quad 1 \leq k \leq K  \tag{26}\\
\sum_{i=0}^{N} \sum_{j=0}^{N} X_{i j}^{k}\left(C_{i j}+S_{i}\right) \leq T^{k} \quad 1 \leq k \leq K  \tag{27}\\
\sum_{j=1}^{N} X_{i j k}=\sum_{j=1}^{N} X_{j i k} \leq 1 \text { for } i=0 \text { and } k \in\{1, \ldots, k\},  \tag{28}\\
\sum_{k=1}^{K} \sum_{j=1}^{N} X_{i j k} \leq K \text { for } i=0, \tag{29}
\end{gather*}
$$

where $C_{i j}$ is the cost incurred on customer $i$ to customer $j, K$ the number of vehicles, $N$ the number of customers, the $S_{i}$ the service time at customer $i, Q^{k}$ the loading capacity of vehicle $k, T^{k}$ the maximal traveling (route) distance of vehicle $k, d_{i}$ the demand at customer $i, X_{i j}^{k} \in 0$ and $1(i \neq j ; i, j \in 0,1, \ldots, N)$.

Equation 25 is the objective function of the problem. Equation 26 is the constraint of loading capacity, where $X_{i j}^{K}=1$ if vehicle $k$ travels from customer $i$ to customer $j$ directly,
and 0 otherwise. Equation 27 is the constraint of maximum traveling distance. Equation 28 makes sure every route starts and ends at the delivery depot. Equation 29 specifies that there are maximum $K$ routes going out of the delivery depot.

### 2.9.3 Permutative Flowshop scheduling problem

In many manufacturing facilities, each job has to undergo a number of operations in given order. The machines which process the jobs are then set up in series and the environment is referred to as flowshop. Moreover, if the jobs cannot skip one another in the queue between machines, i.e. first-in-first-out principle applies, the environment is an instance of permutative flowshop. The optimal schedule is given by the permutation of the order of jobs. If the objective is to minimise the makespan, the sheduling problem is given in the standard notation as:

$$
F m|p r m u| C_{\max }
$$

where the $C_{\text {max }}$ denotes the makespan objective, the completion time of the last job on last machine. This problem is proven to be strongly NP-hard. Being one of the basic scheduling problems, it has attracted much attention in the research in past years.

The problem is formulated as follows: Given the order of $n$ jobs to be processed on $m$ machines in series, the processing time $p_{i, j}$ of job $j$ on machine $i$, and the permutation schedule $j_{1}, \ldots, j_{n}$, the completion time of a job $j_{k}$ on machine $i$ can be computed by the set of recursive equations:

$$
\begin{array}{rlrl}
C_{i, j_{1}} & =\sum_{l=1}^{i} p_{l, j_{1}} & & i=1, \ldots, m \\
C_{1, j_{k}} & =\sum_{l=1}^{k} p_{1, j_{l}} & & k=1, \ldots, n \\
C_{i, j_{k}} & =\max \left(C_{i-1, j_{k}}, C_{i, j_{k-1}}\right)+p_{i, j_{k}} & i=2, \ldots, m ; k=2, \ldots, n \tag{32}
\end{array}
$$

The makespan of the schedule is given as $C_{m} a x=\max \left(C_{1}, \ldots, C_{n}\right)$ [89].

### 2.9.4 Flowshop with Zero Intermediate Storage

One of the most challenging and practical scheduling problem in the flowshop class is the one with no storage or stoppage between machines [88]. Consider a flow shop with zero intermediate storage (FSSZIS) subject to different operating procedures. A job, when it goes through the system, is not allowed to wait at any machine. For this process, all subsequent machines have to be idle, at the completion of the job on a machine upstream. Therefore, the jobs are pulled down the line by machines which have become idle. This constraint can be also refereed to as the no-wait constraint, and minimising the makespan in such a flow shop is referred to as the

$$
F m|n w t| C_{\max }
$$

Among all types of scheduling problems, FSSZIS owns lots of important applications in different industries such as chemical processing [96], food processing [39], concrete ware production [37], and pharmaceutical processing [94] amongst others.

For the computational complexity of the FSSZIS scheduling problem, [35] proves that it is strongly NP-complete. Therefore, only small size instances of this flowshop problem can be solved with reasonable computational time by exact algorithms.

The following notations are used to formulate the FSSZIS problem: assume $n$ as number of jobs to be scheduled, $m$ as the number of machines in the flowshop, $t_{i, j}$ as the processing time for the $i^{t h}$ job on the $j^{t h}$ machine, $d_{i, k}$ as the minimum delay on the first machine between the start of job $i$ and job $k$ due to the no-wait constraint, $[i]$ as the job processed in position $i, C_{[i]}$ as the completion time of the job processed in position. TFT represents the total flow time, i.e. the sum of flow times of all jobs.

The minimum delay time $d_{i, k}$ and completion time $C_{[i]}$ can be calculated as:

$$
\begin{align*}
& d_{i, k}=t_{i, 1}+\max _{2 \leq j \leq m}\left(\sum_{p=2}^{j} t_{i, p}-\sum_{p=1}^{j-1} t_{k, p}\right) \\
& C_{[i]}=\sum_{j=1}^{m} t_{[1], j},  \tag{33}\\
& C_{[i]}=\sum_{k=2}^{i} d_{[k-1],[k]}+\sum_{j=1}^{m} t_{[1], j}, \quad i=2,3, \ldots, n .
\end{align*}
$$

All jobs are assumed to be available at time zero, the total flow time can then be given as in (34).

$$
\begin{align*}
& \text { TFT }=\sum_{i=2}^{n}\left(\sum_{k=2}^{i} d_{[k-1],[k]}+\sum_{j=1}^{m} t_{[1], j}\right)+\sum_{j=1}^{m} t_{[1], j}= \\
& \sum_{i=2}^{n} \sum_{k=2}^{i} d_{[k-1],[k]}+\sum_{i=1}^{n} \sum_{j=1}^{m} t_{[i], j}=  \tag{34}\\
& \sum_{i=2}^{n}(n+1-i) d_{[i-1],[i]}+\sum_{i=1}^{n} \sum_{j=1}^{m} t_{i, j}
\end{align*}
$$

where $\sum_{i=1}^{n} \sum_{j=1}^{m} t_{i, j}$ is the sum of the processing time of all jobs in all machines [11].

### 2.9.5 Lot Streaming Problem

The lot-steaming problem with setup time considered in this paper is a subset of the generic flowshop scheduling problem. Whereas, in the permutative flowshop problem, each job $n$ is processed by a single machine $m$, in a lot-streaming variant, each job is divided into smaller tasks called lots (l) [83]. Once the processing of a sub-lot on its preceding machine is completed, it can be transferred to the downstream machine immediately. However, all $l(j)$ sub-lots of job $j$ should be processed continuously as no intermingling or exchanging is allowed. A separable sequence-dependent setup time is necessary for the first sub-lot of each job $j$ before it can be processed on any machine $k$ [84].

Two different cases of the problem are available; the idling and the non-idling case. The idling case is the simpler variant of the problem, where only the schedule of the lots is taken into consideration. A non-idling case on the other hand is more practical. A nonidle case arises when the machine is not allowed to be idle. This is beneficial, especially in the case when a number of machines are in operation, and resources, such as electricity, are wasted. Another practical example is when expensive machinery is employed. Idling of such expensive equipment is often not desired. In this paper, only the non-idling case is considered.

For a detailed description of the lot-streaming problem please refer to [98].

Non-Idling Case The constraint in this case is that at any given time a machine can process only one sub-lot, and each sub-lot can only be assessed individually. Let the processing time of each sub-lot of job $j$ on machine $m$ be $P(m, j)$, and the setup time of job $j$ on machine $m$, after having processed job $j$ is $s(m, j, j)$, which can also represent the setup time of job $j$ if it is the first job to be proceeded on the machine. The objective is to find a sequence with the optimal sub-lot starting and completion times to minimise the makespan.

The permissible job permutation can be presented as $\pi=\left\{\pi_{1}, \pi_{2}, \ldots, \pi_{n}\right\}$, and the earliest start and completion time as $S(m, j, r)$ and $C(m, j, r)$, where $r$ represents the specific sub-lot on job $j$ being processed on machine $m$.

For the non-idling case, the earliest start time for the first sub-lot is given in equations (35) and (36), where the start time is the maximum of the setup time of the job in the current machine, the completion time of the first sub-lot on the previous machine, and the difference between the completion time of the whole job on the previous machine and the total processing time of the whole job on the preceding machine except the last sub-lot. This ensures that there is no idling time between two adjacent sub-lots. The last two directives of these equations calculate the completion time for the first job.

The subsequent processing times of the following job sequence are given in equations (37) and (38).

$$
\left.\begin{array}{c}
S\left(1, \pi_{1}, 1\right)=s\left(1, \pi_{i}, \pi_{i}\right) \\
C\left(1, \pi_{1}, l\left(\pi_{1}\right)\right)=S\left(1, \pi_{1}, 1\right)+l\left(\pi_{1}\right) \times P\left(1, \pi_{1}\right) \\
S\left(w, \pi_{1}, 1\right)=\max \left\{\begin{array}{c}
s\left(w, \pi_{1}, \pi_{1}\right), S\left(w-1, \pi_{1}, 1\right)+ \\
p\left(w-1, \pi_{1}\right), \\
C\left(k-1, \pi_{1}, l\left(\pi_{1}\right)\right)- \\
\left(l\left(\pi_{1}\right)-1\right) \times P\left(1, \pi_{1}\right)
\end{array}\right\}, \\
C\left(w, \pi_{1}, l\left(\pi_{1}\right)\right)=S\left(w, \pi_{1}, 1\right)+l\left(\pi_{1}\right) \times P\left(w, \pi_{i}\right), \\
w=2,3, \ldots, m
\end{array}\right\} \begin{aligned}
& S\left(1, \pi_{1}, 1\right)=C\left(1, \pi_{i-1}, l\left(\pi_{i-1}\right)\right)+s\left(1, \pi_{i-1}, \pi_{i}\right), \\
& C\left(1, \pi_{1}, l\left(\pi_{1}\right)\right)=S\left(1, \pi_{1}, 1\right)+l\left(\pi_{1}\right) \times P\left(1, \pi_{1}\right), \\
& i=2,3, \ldots, n \tag{37}
\end{aligned}
$$

$$
\left.\begin{array}{c}
S\left(w, \pi_{1}, 1\right)=\max \left\{\begin{array}{c}
S\left(w-1, \pi_{i}, 1\right)+P\left(w-1, \pi_{1}\right), \\
C\left(w-1, \pi_{1}, l\left(\pi_{1}\right)\right)- \\
\left(l\left(\pi_{1}\right)-1\right) \times P\left(1, \pi_{1}\right), \\
C\left(w-1, \pi_{i-1}, l\left(\pi_{i-1}\right)\right)+ \\
S\left(1, \pi_{i-1}, \pi_{i}\right)
\end{array}\right\},  \tag{38}\\
i=2,3, \ldots, n, w=2,3, \ldots, m
\end{array}\right\},
$$

The makespan for the non-idling case can be then calculated as equation (39).

$$
\begin{equation*}
C_{\max }(\pi)=C_{T}\left(m, \pi_{n}, l\left(\pi_{n}\right)\right) \tag{39}
\end{equation*}
$$

The objective of the lot-streaming flow shop scheduling problem with makespan criterion is to find a permutation $\pi^{*}$ in the set of all permutations $\Pi$. It can be given as in the equation (40) [84].

$$
\begin{equation*}
C_{\max }\left(\pi^{*}\right) \leq C_{\max }(\pi), \forall \pi \in \Pi \tag{40}
\end{equation*}
$$

### 2.10 Continuous Optimisation Problems

This section gives the brief overview of the selected common test functions used for proving the properties and efficiency of evolutionary algorithms for continuous optimisation. For each test function, the equation and the position of global minimum (if known) is given. The test functions were taken from [130], more information can be found in [121].

### 2.10.1 Schwefel's function

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n}-x_{i} \sin \left(\sqrt{\left|x_{i}\right|}\right) \tag{41}
\end{equation*}
$$

The global minimum value can be obtained by the following equation:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-418.9829 n \tag{42}
\end{equation*}
$$

for the arguments $x_{i}=420.9687, i=1, \ldots, n$.

### 2.10.2 1st De Jong's function

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n} x_{i}^{2} \tag{43}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{44}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.3 3rd De Jong's function

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n}\left|x_{i}\right| \tag{45}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{46}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.4 4th De Jong's function

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n} i x_{i}^{4} \tag{47}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{48}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.5 Rosenbrock (2nd De Jong's function)

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1} 100\left(x_{i}^{2}-x_{i+1}\right)^{2}+\left(1-x_{i}\right)^{2} \tag{49}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{50}
\end{equation*}
$$

is at $x_{i}=1, i=1, \ldots, n$.

### 2.10.6 Rastrigin

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=2 n \sum_{i=1}^{n} x_{i}^{2}-10 \cos \left(2 \pi x_{i}\right) \tag{51}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-200 n \tag{52}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.7 Griewangk

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=1+\sum_{i=1}^{n} \frac{x_{i}^{2}}{4000}-\prod_{i=1}^{n} \cos \left(\frac{x_{i}}{\sqrt{i}}\right) \tag{53}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{54}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.8 Sine Envelope Sine Wave

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-\sum_{i=1}^{n-1}\left(0.5+\frac{\sin \left(x_{i}^{2}+x_{i+1}^{2}-0.5\right)^{2}}{\left(1+0.001\left(x_{i}^{2}+x_{i+1}^{2}\right)\right)^{2}}\right) \tag{55}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-1.4915(n-1) \tag{56}
\end{equation*}
$$

### 2.10.9 Stretched V Sine Wave

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(\sqrt[4]{x_{i}^{2}+x_{i+1}^{2}} \sin \left(50 \sqrt[10]{x_{i}^{2}+x_{i+1}^{2}}\right)^{2}+1\right) \tag{57}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{58}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.10 Ackley's function I

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(\frac{1}{e^{5}} \sqrt{x_{i}^{2}+x_{i+1}^{2}}+3\left(\cos \left(2 x_{i}\right)+\sin \left(2 x_{i+1}\right)\right)\right) \tag{59}
\end{equation*}
$$

The global minimum value (for $n \geq 3$ ) of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-7.54276-2.91867(n-3) \tag{60}
\end{equation*}
$$

### 2.10.11 Ackley Two

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(20+e-\frac{20}{e^{0.2 \sqrt{\frac{x_{i}^{2}+x_{i+1}^{2}}{2}}}}-e^{0.5\left(\cos \left(2 \pi x_{i}\right)+\cos \left(2 \pi x_{i+1}\right)\right)}\right) \tag{61}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=0 \tag{62}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.12 Egg Holder

$f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(-x_{i} \sin \left(\sqrt{\left|x_{i}-x_{i+1}-47\right|}\right)-\left(x_{i+1}+47\right) \sin \left(\sqrt{\left|x_{i+1}+47+\frac{x_{i}}{2}\right|}\right)\right)$

### 2.10.13 Michalewicz

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(-1\left(\sin \left(x_{i}\right) \sin \left(\frac{x_{i}^{2}}{\pi}\right)^{20}+\sin \left(x_{i+1}\right) \sin \left(\frac{2 x_{i}^{2}}{\pi}\right)^{20}\right)\right) \tag{64}
\end{equation*}
$$

The global minimum value (for $n>2$ ) of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=1.00098(n-2) \tag{65}
\end{equation*}
$$

### 2.10.14 Masters Cosine Wave

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=1}^{n-1}\left(e^{\frac{-\left(x_{i}^{2}+x_{i+1}^{2}+0.5 x_{i+1} x_{i}\right)}{8}} \cos \left(4 \sqrt{x_{i}^{2}+x_{i+1}^{2}+0.5 x_{i} x_{i+1}}\right)\right) \tag{66}
\end{equation*}
$$

The global minimum value of:

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-1 \cdot n \tag{67}
\end{equation*}
$$

is at $x_{i}=0, i=1, \ldots, n$.

### 2.10.15 Shekel's Foxhole

$$
\begin{equation*}
f\left(x_{1}, \ldots, x_{n}\right)=-1 \sum_{j=1}^{m} \frac{1}{c_{j}+\sum_{i=1}^{n}\left(x_{i}-a_{j, i}\right)^{2}} \tag{68}
\end{equation*}
$$

Where recommended value of $m=30$, and constants $c_{j} ; j=1, \ldots, m$ and $a_{j, i} ; j=$ $1, \ldots, m ; i=1, \ldots, n$ are constant numbers fixed in advance.

## 3 Implementation

This section presents the description of design and implementation of each of the programs. All programs were developed as independent command line applications. Parameters are provided through the combination of command line arguments and configuration files. All source codes in C/C++ and CUDA C can be found on CD, together with short manuals and examples of usage (see appendix A).

### 3.1 CUDA based NEH

In this section, the parallel version of NEH algorithm is presented. As discussed in section 2.8, the algorithm uses both the CPU and the GPU. For the most applications, it is desirable to maximally reduce the amount of data transferred between CPU and GPU, because PCI Express is relatively slow and excessive transfers can considerably decrease performance. It is obvious, from the analysis of sequential NEH (Section 2.2), that there exists data dependency in each step of the main iteration. Whereas the process of exploring all the variants derived by extending the current subsequence (partial solution) by the next job consists of generating several alternative solutions and their evaluation, where each solution is independent from all the others, and hence can be implemented as parallel, the best partial solution (subsequence) must then be chosen and used as a basis for the next iteration step (for generating the next set of partial solutions), which requires synchronization. From these considerations stems the design of CUDA based NEH algorithm.

The main loop (encompassing step 3 and 4 of the sequential NEH description) runs on the CPU, due to the afore mentioned data dependency. The algorithm flow inside the main loop can be divided into four parts, each of which can be run in parallel. The basic structure of the algorithm can be described as follows:

Main loop: Until full solution found, do:
Step 1: Generate the candidate subsequences (solutions) from the current subsequence.
Step 2: Evaluate candidate subsequences.
Step 3: Find the best (minimal cost) solution amongst all candidates.
Step 4: Update current subsequence.

### 3.1.1 Generating the candidate subsequences, Evaluation

Evaluating subsequences, i.e. calculating the problem cost function, is parallelized in a simple way - each solution is evaluated by one thread of one block - therefore all costs are calculated in parallel, but no further parallelism is exploited inside the calculation of a single solution cost function, as main objective of this paper is to explore the possibility of parallelisation of the NEH heuristics itself, rather than that of FSS problem, which was done in [16]. To speed up the calculation, shared memory was used. Full
machines $\times$ jobs completion time matrix of FSS makespan problem would have consumed too much memory space, therefore it was reduced to only $2 \times$ jobs (only 1 last machine completion times for all jobs are remembered in each step, the completion time for subsequent machine is stored into 2nd table row, the rows are then swapped before the next step).

Generation of candidate solutions is fully parallel - each block of threads is responsible for generating a single candidate solution, which means performing a single insert on current sequence. The position into which the next job is inserted in the candidate solution corresponds to blockId. Each thread in a block shifts subset of solution elements (jobs), using shared memory. The generated candidate solution could then be stored into global memory and then read again and evaluated in a separate kernel. However, as the kernel for generating the solution was relatively small, it was merged with the kernel performing the evaluation to avoid this delay caused by additional write/read operation on the global memory. In the merged kernel, the solution is first generated, then written into global memory. All the threads in a block apart from the first thread are terminated, the remaining thread performs the evaluation of the solution (while it is still in shared memory), taking advantage of a memory with lower latency, finally storing the calculated cost into global memory.

### 3.1.2 Find the minimal cost solution

The search for the index of the minimal cost in the array of solutions costs is done using a parallel reduction pattern, employing shared memory to store the data being processed. In the beginning, the data is loaded from global into shared memory. In each step, each active thread compares two costs, and stores the smaller of the two costs on the place of the first cost, along with its original index (cost is represented as a structure containing two elements: cost value, and cost index). After each step, the number of active threads is reduced by half. In the end, the first element of the costs array contains the minimal cost found, along with its respective solution index. This pair is then written into global memory.

### 3.1.3 Update current subsequence, device synchronization

Finally a simple kernel copies the best solution, based on its stored index, into the current solution buffer, and the next step of the main loop can be performed. However, before it can be started, a global CUDA device synchronization is necessary for a big data (for a job schedule size/number of threads in a block of size more than approximately 100, as was empirically confirmed). As each of the kernels consumes some of the GPU resources, it is necessary to wait, until the pending kernels completely finish the execution, and release their resources, otherwise the GPU freezes and unsuccessful kernel launches start to appear. This is done by calling cudaDeviceSynchronize () function from the host code, after the Update kernel is launched.

The following figure (13) depicts the memory layout of the afore described code (without FSS input data, for the current subsequence size 2, full schedule size 4 . The data fields
not used in the current step are grayed out). The candidate solutions are stored in one global memory 1D array, which conceptually represents 2D array, wherein each row contains one candidate schedule. The respective costs are stored in a separate array. The FSS problem input data (processing times of each job on each machine) are stored in the similar fashion in global memory (because of its large size).

Figure 13: CUDA based NEH memory layout
This implementation is expected to provide in each step the speedup proportional to the number of solutions generated.

### 3.2 CUDA based 2-opt algorithm

This section presents the parallel CUDA based version of 2-opt algorithm for permutative flowshop with makespan criterion problem. Before coming to the parallel implementation description however, the more detailed pseudocode of sequential version is provided in Algorithm 4, in order to enable better understanding of the CUDA version design.

```
Input:
S: initial solution
1
    // number of jobs
N}\leftarrow\operatorname{Size}(S
    // objective function value of S
f
    // temporary solution memory
T\leftarrowS
while ImprovementFound do
        ImprovementFound }\leftarrow\mathrm{ False
        for i=1 to N-1 do
            for j=i+1 to N do
                T\leftarrowSwap(T,i,j)
                fT}\leftarrow\textrm{f}(T
                if }\mp@subsup{f}{T}{}<\mp@subsup{f}{S}{}\mathrm{ then
                    S\leftarrowT
                f
                ImprovementFound }\leftarrow\mathrm{ True
                break(2)
            end
            T\leftarrowSwap(T,j,i)
        end
        end
end
return S
```

Algorithm 4: 2-opt sequential version. The $\operatorname{Swap}(T, j, i)$ procedure swaps $j$-th and $i$-th job of schedule $T$

As can be seen already from the analysis of description of 2-opt presented in Section 2.3 , the task that can be done in parallel is the exploration of neighbourhood of the current solution. This is divided between individual CUDA blocks. Each block explores approximately the same amount of possible neighbours to the current solution (in the worst case, when no improving solution is found), including the cost evaluation. However, if it finds an improving solution, that solution is stored into the global memory allocated for each block, and the block terminates. If at least one of the blocks found an improving
solution, the minimal cost solution amongst all blocks is found and stored into memory as the current solution for the next iteration. Otherwise, the current solution is returned. The cost function evaluation itself was not parallelized, in each block only a single thread performs this task.

The outline of the parallel algorithm can be given as follows:

Step 1: Set current solution $S=$ Initial solution
Step 2: Explore the neighbourhood of $S$ by $G$ blocks in parallel. In each block $b$ :
Step 1.1: Determine initial index $i$ for $b$
Step 1.2: Explore all neighbours of $S$ created by swapping of $i$ and $j, j \in\{1, \ldots, N\}$. If improving neighbour $T$ found, go to step 1.4.
Step 1.3: Determine next index $i$ for $b$. If $i \geq N$, terminate. Otherwise go to step 1.2.
Step 1.4: Store $T$ and its objective function value $f_{T}$ into global memory and terminate.

Step 3: If no improving solution found, exit procedure and return $S$ as the best solution found. Otherwise determine the best solution amongst those found by blocks in parallel.

Step 4: Store best solution as $S$. Go to step 2
Where $N$ is the number of jobs in the schedule and $i$ is the outer loop index (see pseudocode 4 for sequential version of 2-opt).

### 3.2.1 Exploration and Evaluation of neighbouring solutions

In this kernel, the neighbours of the solution are generated and evaluated. It is obvious from the sequential version pseudocode (Algorithm 4), that the tasks of generating individual neighbours by swapping every possible pair of jobs $(i, j)$ for $i=1, \ldots, N$ and $j=i+1, \ldots, N$ can be considered independent and executed in parallel. The shared memory is used to store the neighbouring solution which is being created and evaluated, as well as 2 rows of completion times matrix necessary for the flowshop makespan evaluation. If the new solution is better than the current one, it is stored into global memory allocated for each block, to avoid data races between blocks (this is illustrated in Figure 14 depicting memory layout for six jobs and four blocks). The improvements counter in global memory is incremented using atomic operation, to reflect this. This counter is compared against zero after the kernel termination, to determine if the stopping criterion of the algorithm was reached. The cost function itself is evaluated by a single thread only; the other threads of a block process the elements of the solution when transferring data between memory locations.

It is however impractical to allocate full number of $(N-1)^{2} / 2$ blocks on the GPU for the most cases, as this number can be very large, whereas the number of SMs and

Figure 14: CUDA based 2-opt memory layout
the number of resident blocks on SM is limited by various factors (discussed in Section 2.8 ), such as the number of threads in a block and a registers/shared memory usage. The roughly optimal number of threads in a block maximizing the number of resident blocks, as well as GPU occupancy, is therefore determined based on the calculations performed in the CUDA occupancy calculator tool [79], as a function of the number of jobs in a schedule (which determines the size of shared memory used). This maximizes the utilization of the GPU, reduces the total global memory size required by grid, as well as the workload done by the search for minimal cost solution in the next kernel, however the mapping of the blocks to the tasks becomes more complicated.

Under the assumption that the number of blocks will be nearly always smaller than the aforementioned function of the number of actual jobs for the problem instances of interest (problems with schedules longer than 30 ), only the outer loop of the sequential 2-opt algorithm was parallelized. The inner loop is performed by each block sequentially. This reduces the data transfers between global and shared memory, and doesn't eliminate the advantage of the low complexity of the swap operation at the same time. If the solution created by swapping jobs $i$ and $j$ is worse than the current one, it is easy to reverse this change by swapping again $j$ and $i$, with constant complexity. Therefore maximally $N-1$ blocks are needed. The mapping of blocks to tasks is illustrated in Figure 15.

Figure 15: CUDA based 2-opt, mapping of blocks to tasks

### 3.2.2 Finding minimal cost index in parallel

This procedure is described in detail in the NEH implementation description, 3.1. The only difference here is, that the smaller number of blocks was used, therefore the searched array size is given by the size of the grid. The best solution's index and cost are stored for the later call to the kernel, which copies the solution at index into the current best solution memory, also described in the NEH Section.

### 3.3 Chaos driven DABC

All of the original variants of DABC, as well as the ABC algorithms (described in Sections 2.5 and 2.4), pay very little attention to stochasticity, despite making heavy use of randomness in their workflow. The stock DABC doesn't suggest any particular pseudo random number generator, and presumes the usage of one of the standard ones. The most commonly used PRNG in evolutionary algorithms is Mersenne Twister, owing to its good stochastic properties and speed [70]. This thesis presents the possibility to improve the standard DABC algorithm by exchanging the PRNG for a chaos based PRNG.

In the first part of research, nine unique chaotic systems have been included as CPRNG for the DABC: Arnold's cat map, Burgers map, Delayed Logistic, Dissipative Standard map, Henon, Ikeda, Lozi, Sinai and Tinkerbell maps. These new chaos embedded algorithms (hereafter referred to as variants) can be collectively labelled as CDABC. The basic premise of this work was to ascertain if any improvement can be achieved in DABC by using chaotic systems in place of PRNG. The experimental results for this with application to FSSLS with setup time and the FSSNW problem are presented in Sections 4.3 and 4.4.

The second part of research concentrates on the CPRNGs that have proven to be the best performing ones, i.e. four of the original nine CDABC variants: $\mathrm{CDABC}_{\mathrm{L}}$ using Lozi map, $\mathrm{CDABC}_{\text {DL }}$ using Delayed Logistic map, $\mathrm{CDABC}_{\mathrm{B}}$ with Burgers map and $\mathrm{CDABC}_{\mathrm{T}}$ with Tinkerbell map. The experimentation for these algorithms applied to solving QAP and CVRP problems is described in Section 4.5.

### 3.3.1 Chaotic pseudo random number generator

There are two options how to utilize the chaos maps to implement the CPRNG. Either the large sequence of numbers - the inception of chaos map - is stored in a file, and used iteratively. This approach, however, consumes large amount of memory. The second option is to use random starting point on the map, and a mathematical equation to get the next points. This concept is similar to the PRNG seed. In this way, it is no longer necessary to store and read large data. For CDABC variants, the latter approach was used. The pseudocode describing this concept is given in Algorithm 5. Values on X-axis are used as the output sequence, whereas values on Y -axis are merely internal memory of the map.

The DABC algorithm structure remains almost the same (as described in pseudocode 3), the only alteration lies in replacement of calls to get next pseudo-random number from PRNG for calls to CPRNG. The detailed CDABC pseudocode is presented in Algorithms 6 to 16 , emphasising the lines which lead to the calls to the pseudo-random number generator that were replaced by the chaos-based one by the red color. These parts are further described in the text and the analysis of the quantity of random numbers generated is provided.

```
begin CPRNG_init:
    Input: seed
        /* set initial point on map: */
        X\leftarrowseed (mod 0.1)
        Y}\leftarrow
end
begin CPRNG_get_next:
        /* compute next X and Y according to given chaotic map
                equation:
    X (n+1)}\leftarrow\mp@subsup{f}{x}{}(\mp@subsup{X}{}{(n)},\mp@subsup{Y}{}{(n)},\mp@subsup{Y}{}{(n+1)}
    Y ^ { ( n + 1 ) } \leftarrow f _ { y } ( X ^ { ( n ) } , Y ^ { ( n ) } , X ^ { ( n + 1 ) } )
    return }\mp@subsup{X}{}{(n+1)}(\operatorname{mod}1
end
```

Algorithm 5: CPRNG pseudocode

### 3.3.2 DABC and CDABC randomness

It has been stated before that DABC heavily relies on stochasticity. Here, the verification of this claim is attempted at, and the quantification of the random numbers (RN) required during the course of algorithm flow is specified. Starting from the pseudocode 6, it can be observed that the random number generation is involved during the main iteration in employed bee, onlooker bee, as well as scout bee phase (lines 11-13), as well as in the initialization phase in population and the list of operations initialization (lines 3 and 8). The list of operations $N L$ is part of the implementation of adaptive strategy described in Section 2.5.

To initialize $N L$, constant number of $N L_{L} \mathrm{RN}$ is needed (where $N L_{L}$ is length of $N L$, specified as parameter of DABC), as can be seen in Algorithm 16. To initialize the population according to Algorithm 13, at least $F S \times n$ RN numbers are needed, where $n$ is number of jobs in a schedule. However, in reality, this number will be certainly much higher. An experiment has been conducted to obtain the average number of RN need in this algorithm with Mersenne Twister for 30 solutions and number of jobs from 10 to 50 . The excerpt from results is shown in table 3, where only every 10 -th row was selected. Mean gives the average quantity of random numbers needed for the initialization of all solutions in the population, Mean/Element column gives the average number of RN needed for an element in the population (Mean / $(F S \cdot n)$, where $F S$ is number of food sources and $n$ number of jobs). With the correlation coefficient of 0.976 , there is linear dependency of RN needed on the number of jobs, which can be formulated, using the results of linear regression, as follows: $R N E=0.037 \cdot n+2.804$, where $n$ is number of jobs and $R N E$ is the average number of RN/element of population. In total in the initialization phase, average $R N=F S \cdot n \cdot R N E+N L_{L}=F S \cdot n \cdot(0.037 \cdot n+2.804)+N L_{L}$.

In the employed bee phase, presented in Algorithm 7, for each food source, RN needed are between 2 and $4+1+\left(\right.$ Loop $\left._{\text {max }} \cdot 2\right)+\left(N L_{L}-W N L_{L}\right)$. The minimal quantity of RN is needed when the operation is simple insert or simple swap (12), and the

```
    Input:
    FS : number of food sources
    Limit : limit of improvements trial at a food source
    Loop max : maximal number of iterations in local search
    PL : probability of local search
    T : number of iterations of algorithm
    NL
    WNLL
    begin initialize:
        /* read in problem data */
    problem}\leftarrow\mathrm{ read_problem()
    /* generate FS food sources as random permutations of sequence 1 to
        number_of_jobs(problem)
    P.\pi}\leftarrow\mathrm{ random_init( FS,1, number_of_jobs(problem))
    /* evaluate food sources */
    P.fitness }\leftarrow\mathrm{ evaluate( P. }\pi\mathrm{ )
    /* initialize limits

$N L_{i} \leftarrow$ Operationso
end
end
end
Algorithm 16: CDABC refill list of operations $N L$
new solution found doesn't improve upon the previous one. Insert and swap require both only 2 random numbers. However, the operation used for the generation of the new solution can be one of the composed operations: insert2, swap2. In such case, 4 random numbers are needed. If the solution does improve upon its predecessor, another RN is needed to determine if the local search should happen. Inside the local search, only simple insert and simple swap operations are needed, which happen in every local search iteration, fixed number of times, Loop $_{\text {max }}$, hence $L_{\text {oop }}^{\text {max }} .2$ random numbers are needed inside local search. If the $N L$ list is empty and has to be refilled, another $\left(N L_{L}-W N L_{L}\right)$ random numbers are needed (where $N L_{L}$ is length of $N L$ list, $W N L_{L}$ length of $W N L$ list). Therefore in employed bee phase, $R N$ is in the range from $F S \cdot 2$ to $F S \cdot\left(5+\left(2\right.\right.$ Loop $\left.\left._{\max }\right)+\left(N L_{L}-W N L_{L}\right)\right)$.

In the onlooker bee phase, shown in Algorithm 8, the number of RNs is between $2+2=4$ and $2+4+\left(N L_{L}-W N L_{L}\right)$ for a solution. Explanation is similar as in the employed bee phase. Two randomly selected solutions are always needed. On the better one, an operation is performed, requiring either two or four randomly selected jobs positions. This makes up the total of $F S \cdot 4-F S \cdot 6+\left(N L_{L}-W N L_{L}\right)$ random numbers.

The scout bee phase, presented in Algorithm 9, is the simplest, requiring between 0 and 6 random numbers in total. If no solution crosses the Limit, no operation is performed. If a solution with exceeded limit exists, exactly 6 random numbers are needed to perform 3 insert operations.

In the main iteration, number of random numbers used is between $F S \cdot 6$ and $F S$. $\left(2\right.$ Loop $\left._{\max }+2\left(N L_{L}-W N L_{L}\right)+17\right)$ per iteration, $T \cdot F S \cdot 6$ and $T \cdot F S \cdot\left(2 L_{\text {oop }}^{\max }+2\left(N L_{L}-\right.\right.$ $\left.W N L_{L}\right)+17$ ) in total. Total quantity of random numbers needed in the algorithm is therefore between $R N_{\text {init }}+T \cdot R N_{\text {iter }}=\left(F S \cdot n \cdot(0.037 \cdot n+2.804)+N L_{L}\right)+T \cdot(F S \cdot 6)$ and $R N_{\text {init }}+T \cdot R N_{\text {iter }}=\left(F S \cdot n \cdot(0.037 \cdot n+2.804)+N L_{L}\right)+T \cdot F S \cdot\left(2\right.$ Loop $_{\text {max }}+$ $\left.2\left(N L_{L}-W N L_{L}\right)+17\right)$. As an example, with the default parameter settings described in 2.5, where $F S=30, L o o p_{\max }=200, T=100, N L_{L}=20$ and $W N L_{L}=15$, for the number of jobs $n=100$, this gives the lower bound of $37.5 \cdot 10^{3}$, and the upper bound of $1.3 \cdot 10^{6}$ random numbers. This analysis gives only the coarse lower, respective upper bound of the quantity of random numbers needed, as the dependencies are neglected for the sake of simplification. Nevertheless, it can be seen that these values are very large, and the use of stochasticity in the algorithm is intensive.

Table 3: Random numbers required in random initialization of population

| Jobs | Elements | Mean | Std | Mean/Element |
| ---: | ---: | ---: | ---: | ---: |
| 10 | 300 | 878.200 | 53.156 | 2.927 |
| 15 | 450 | $1,515.900$ | 82.313 | 3.369 |
| 20 | 600 | $2,142.100$ | 114.319 | 3.570 |
| 25 | 750 | $2,895.867$ | 181.762 | 3.861 |
| 30 | 900 | $3,607.433$ | 218.697 | 4.008 |
| 35 | 1050 | $4,309.767$ | 147.940 | 4.105 |
| 40 | 1200 | $5,144.633$ | 279.140 | 4.287 |

| 50 | 1500 | $6,786.667$ | 306.522 | 4.524 |

### 3.4 Centralities Based ABC

In the Adaptive ABC algorithm, the complex network analysis was used for adaptive control of the population. The structure of the algorithm is as follows: firstly, the weighted adjacency matrix is being created throughout the algorithm iterations, for some fixed number of iterations, a fraction of the total expected number of iterations before algorithm termination. The complex network recorded this way is then analysed, and this information is subsequently used to identify the nodes (solutions) that don't play a significant role in the population dynamics. In this algorithm, such nodes are replaced by the new randomly generated ones, although different schemas of the replacements generation could also be used.

The measures used to identify the nodes that do not contribute significantly to the population improvement were chosen to be the three types of vertex centrality, the weighted degree centrality (strength), closeness and betweenness centrality, as described in section 2.7.2.

The vertices representing solutions are ranked according to these measures, and the fixed ratio of the solutions corresponding to the lowest ranking nodes is removed and regenerated. The adjacency matrix is then reset. The entire procedure of network recording and the nodes ranking and replacement is repeated until the algorithm terminates. This concept is illustrated in figures 16-19.

Figure 16: The network with labelled nodes ranked by centrality. The larger centrality nodes are marked in bigger size and different colors. The smallest blue nodes have the lowest centrality, the largest red node has the highest centrality value.

Figure 17: The nodes sorted according to their centrality score in ascending order. The first Cutoff $\times$ NS nodes will be removed.

Figure 18: The nodes marked in gray will be removed from the network.

Figure 19: The network after the low centrality nodes removal. The most important nodes are preserved.

Employing these three distinct vertex influence measures, two variants of the Adaptive ABC algorithm were created, both combining the usage of all three of them: the 1st variant (Adaptive ABC 1, Algorithm 17) in the phase of network analysis conceptually splits the population into three parts. Each of them is evaluated using different centrality measure type on the same network. As described in the pseudocode, in the network analysis and nodes pruning phase of the algorithm, first $\frac{N S}{3}$ nodes are sorted, according to the first centrality measure (weighted degree centrality). $\frac{N S}{3} \times$ Cutoff lowest ranking nodes are recreated, and the same procedure is repeated for the second third of the population using closeness, and for the last third of the population using betweenness.

The 2nd variant (Adaptive ABC 2, Algorithm 18) uses three fully separated subpopulations, each with their own network. Each of them is evaluated using different centrality measure type. After the less influential nodes are pruned and the networks reset, the tournament selection of size two is performed to select every next-generation solution of every sub-population, choosing the better of two solutions randomly selected from all three sub-populations. In this way the information sharing between sub-populations is ensured.

In order to explore the influence of distinct centralities on the speed of convergence, a simpler version of Adaptive ABC was created. This version, named Adaptive ABC 3, takes the centrality measure to be used for network analysis and nodes evaluation as a parameter. The algorithm is described by pseudocode given in 19.

All of the previously discussed Adaptive ABC variants determine the nodes to be

```
Input:
NS : number of solutions in the population

            reset Network and NGenCounter
    end
    increase GenCounter
    increase NGenCounter
end
```

Algorithm 19: Adaptive ABC 3
removed from the population merely by their vertex centrality ranking, in accordance with the main premise of this research. The quality of the solutions themselves is not taken into consideration. This, however, can lead to the removal of the good quality solutions from the population, in case they haven't contributed to the other solutions for given number of generations, therefore somewhat more randomizing the search. The convergence could be faster if some of the good solutions were maintained, i.e. if the quality of the solution was also considered when determining which nodes to remove. From this idea stem two more variants, based on the Adaptive ABC 3: Adaptive ABC 3.b, described in 20, and the Adaptive ABC 3.c, described in 21.

Both algorithms work in the similar fashion: two sorted lists of nodes are created. One of them sorts nodes by the centrality ranking, using the centrality measure type provided as parameter. The other one sorts nodes by the solution costs or fitness, so that the nodes belonging to the solutions with the best fitness come first. Certain number of solutions with the best fitness values is always preserved, regardless of the centrality ranking of the respective vertices in the network. This number is determined by the parameter EliteRatio, giving the ratio of the best solutions from entire population to always maintain during the nodes pruning.

In case of the Adaptive ABC 3.b, the first Cutoff $\times$ NS nodes are considered for the removal in the same way as in the previously described algorithm variants. However, if any of these nodes belongs to the first EliteRatio $\times$ NS best solutions, it is skipped in the pruning process. Hence this algorithm recreates Cutoff $\times N S$ nodes or less in the network analysis and nodes pruning phase.

The Adaptive ABC 3.c, on the other hand, in the most cases recreates the full number of Cutoff $\times$ NS nodes. It goes through the entire list of the nodes sorted by centrality ranking. The removed solutions are counted during the procedure of the nodes pruning. If the low ranking node is amongst the first EliteRatio $\times$ NS best solutions, it is again skipped. In the opposite case, it is replaced by the new solution, and the removed solutions counter is increased. The procedure does not end before the counter reaches value of Cutoff $\times$ NS, or the end of the nodes list is reached.

[^0]Algorithm 20: Adaptive ABC 3.b

```
Input:
NS : number of solutions in the population
NGenNumber : number of generations for network creation
CutoffRatio : ratio of low centrality ranking nodes to be recreated
MeasureType : centrality measure type to be used EliteRatio : ratio of the best cost
solutions to always keep in the population
1
Generate initial population Population of NS solutions
Initialise the network Network
initialise generation counter GenCounter
initialise network generation counter NGenCounter
while max generation not reached do
    send Employed bees and update the Network
    send Onlooker bees and update the Network
    send Scout bees
    memorize the best solution
    if NGenCounter == NGenNumber then
        calculate centrality MeasureType of all NS nodes
        nodesByCentrality }\leftarrow\mathrm{ sort nodes by the centrality ranking in ascending order
        nodesByCost }\leftarrow\mathrm{ sort nodes by corresponding solutions' fitness value in
        ascending order
        removed }\leftarrow
        for i=1 to NS do
            node \leftarrow nodesByCentrality[i]
            if node not in nodesByCost[1 to NS }\times\mathrm{ EliteRatio] then
            replace the solution belonging to the node by new one
            removed }\leftarrow\mathrm{ removed + 1
                end
            if removed }\geqNS\timesCutoffRatio then
                    break
            end
        end
        reset Network and NGenCounter
    end
    increase GenCounter
    increase NGenCounter
end
```

Algorithm 21: Adaptive ABC 3.c

## 4 Experimentation

The following text describes the experimentation performed for the implemented algorithms solving selected optimisation problems. It provides the information on the problem instances solved, as well as parameter setting and the hardware used for testing. First five parts, the NEH, 2-opt algorithm, CDABC for FSSLS, FSSNW, QAP and CVRP belong to the combinatorial optimisation domain, the last part, Centralities Based ABC, solves the standard continuous optimisation test functions. Experiment outputs are provided on CD (see appendix, A). Statistical analysis of this data of each experiment is found in Section 5.

### 4.1 NEH

This section presents the experimentation performed on the standard and CUDA accelerated implementation of NEH heuristic, comparing execution times. NEH is used to solve the problem of minimising the makespan of permutative flowshop scheduling problem. In order to obtain the input data, which would be large enough, Taillard Data Sets were extended with the new larger problem instances. The experimental data are described in the following text parts. The analysis of results is discussed in Section 5.1.

### 4.1.1 Extended Taillard Data Sets

The entire experimentation is conducted on the Taillard flowshop data sets. The original data sets comprise of twelve data sizes (indexed hereafter as (jobs x machines)); $20 \times 5,20$ x $10,20 \times 20,50 \times 5,50 \times 10,50 \times 20,100 \times 5,100 \times 10,100 \times 20,200 \times 10,200 \times 20$ and 500 $x 20$. The formulation of these data sets is given in [108].

One of the core premises of the GPU approach is the ability to set up massive parallel computation array to speed up the execution. Therefore, the original Taillard flowshop data sets (OTS) were extended to include new higher dimensional problems. Using the code snippet posted on the OR Library [111] by J. Beasley [9] detailing the Taillard code generation, four new higher dimensional data sets were generated, hereafter termed as the extended Taillard data sets (ETS). The sizes of the new data sets are $500 \times 50,700$ $\times 20,700 \times 50$ and $1000 \times 20$. Each data set contains ten unique instances. Using the Taillard code template, each new seed instance was uniquely generated within the range $\left\{2^{24},\left(2^{31}-1\right)\right\}$ using a uniform distribution. Using this seed, the new instance was generated. The full C code including all the new instances can be obtained from the repository at [22].

### 4.1.2 Experiment setup

The experimentation was conducted on the server housed at the Media Research Lab (MRL) at the VSB-Technical University of Ostrava. The specifications for the CUDA GPU are: Kepler generation, production line Tesla K20k, 4.8GB global memory, GPU Clock rate
of 706MHz with 2494 CUDA cores; CUDA Driver Version 5.5. The CPU specifications are: Intel Xeon CPU E5-2640 v 2 with 2.00 GHz processor and 8 CPU cores.

The experiments on all the afore mentioned problem instances of varying size (16 unique instance sizes, 10 instances of each size) were performed for both the CPU and the GPU based implementation. The resulting times in milliseconds were recorded and statistically analysed and compared. The excerpts from the results are given in the Tables 4 and 5 (both tables contain execution times and best schedules costs for first three problem instances of each size. Entire experimentation data were too large to fit the publication scope, but can be found on CD (appendix A). The statistical summary is given in the results analysis of NEH, in the afore mentioned Section 5.1.

Table 4: NEH on CPU, raw data excerpt.

### 4.2 2-opt algorithm

In this section, the experimentation performed on CUDA accelerated 2-opt and the sequential implementation of 2 -opt for permutative flowshop with makespan criterion is described, comparing primarily the execution times, but also the solutions costs. The subset of standard Taillard data set was used (described in Section 4.4), with the problem instance size given in machines $\times$ jobs $(m \times n)$ varying from $5 \times 20$ to $20 \times 200$. Eleven different sizes were used. Of each size, three different instances were evaluated. The description of the experiment setup follows, with the analysis of results given in 5.2.

### 4.2.1 Experiment setup

The experimentation was conducted on the server at the Media Research Lab (MRL) at the VSB-Technical University of Ostrava. The specification of the platform is given in 4.1.

The 2 -opt algorithm requires an initial solution. In order to make simple and valid comparison between sequential and accelerated version, both were in each experiments started on the same solution defined by the jobs indices sorted in ascending order from 1 to $n$, where $n$ is total number of jobs. The solution found slightly differs between sequential and parallel implementation, moreover, in parallel version the solution found is dependent on the number of blocks in the grid, however the semantics of the algorithm is similar. It could be expected that the accelerated version would produce better solutions on average, as the selection of the best solution from the solutions found by several blocks is incorporated in the algorithm. Because of this asymmetry, the analysis contains also the comparison of the solutions costs.

As stated before, the analysis of the experiments is presented in Section 5.2. The full experiment results are not included due to the space limitations, but can be found on CD (appendix A). The excerpt from the experiment results is presented in Tables 6 for the sequential version, and 7 for the parallel version. Only the solution costs and execution times are included.

Table 6: 2-opt algorithm on CPU, raw data excerpt.

| Instance | Dimension | Time[ms] | Cost |

### 4.3 Chaos driven DABC for FSSLS

The experiments performed on Chaos driven DABC for the lot-streaming flowshop scheduling problem with setup time, no-idle case, as well as chaos generated data sets used for testing, are described in the following text.

### 4.3.1 Chaotic maps generated data sets

In keeping with the theme of utilising the chaotic maps in lieu of PRNG, the data sets have been generated using two unique chaotic maps; the Lozi and the Dissipative map. Five unique sizes of data sets have been generated. They are from 10 jobs $x 5$ machines, 20 jobs x 10 machines, 50 jobs x 25 machines, 75 jobs x 30 machines and 100 jobs x 50 machines. There are 5 instances for each data set size, therefore, in total 25 data set instances for each of the Lozi and Dissipative data sets.

In order to have unique data sets, each instance was initialised from a unique start position of the respective chaotic system. Additionally, the map was not allowed to be reinitialised. Two different maps were used in order to gain more diversity, due to their different maps in the data sets, and to remove any particular bias when using any one system.

The datasets are available at [21] for download.

### 4.3.2 Experiment setup

The operating parameters of CDABC are given in Table 8. All parameters were kept constant for all the experimentation, in order not to introduce a bias. All experiments were conducted on the machine having Intel i7-3610QM CPU processor running at 2.3 GHz with 8GB of RAM. All codes were written in the C programming language, compiled with the gcc 4.6.2.

Table 8: DABC Operating parameters, FSSLS

| Parameter | Value |
| :--- | :--- |
| Food Source (FS) | 30 |
| Limit (food source) | 50 |
| Loop $_{\text {max }}$ (Local Search) | 200 |
| Local search probability $\left(P_{L}\right)$ | 0.2 |
| Neighbourhood List (NL) | 20 |
| Winning Neighbourhood List (WNL) | $0.75 \times$ NL |
| Iterations | 100 |

For each instance, fifteen (15) repeated experimentations were conducted in order to obtain statistical variance. Therefore, 375 individual experiments were conducted on the Lozi and Dissipative data sets, a total of 750 experimentations. The excerpts from the results for both data sets are given in Tables 9 and 10. Only cost values and execution times are shown for a selected subset of instances, for every instance and every CPRNG, only 3 experiments are shown out of actually conducted 15 . The averaged results together
with analysis is given in Section 5.3. The full experiment results with schedules can be found on $C D$ (appendix A).

Table 9: CDABC for FSSLS, Lozi data set, raw data excerpt.

### 4.4 Chaos based DABC for FSSNW

The experimentation conducted on CDABC for Flowshop with no wait constraint is presented in the following text. The entire experimentation was conducted on the Taillard data sets [109], which is a set of 12 data classes of different sizes, each of which contains ten unique instances; therefore a total of 120 data instances.

### 4.4.1 Experiment setup

The operating parameters of CDABC are given in Table 11. All parameters were kept constant for all the experimentation, in order not to introduce a bias. All experiments were conducted on the machine having Intel i7-3610QM CPU processor running at 2.3 GHz with 8GB of RAM. All codes were written in the C programming language.

Table 11: DABC Operating parameters, FSSNW

| Parameter | Value |
| :--- | :--- |
| Food Source (FS) | 30 |
| Limit (food source) | 50 |
| Loop (Local Search) | 200 |
| Local search probability $\left(P_{L}\right)$ | 0.2 |
| Neighbourhood List (NL) | 20 |
| Winning Neighbourhood List (WNL) | $0.75 \times$ NL |
| Iterations | 100 |

For each instance, fourteen (14) repeated experimentations were conducted by each variant of CDABC in order to obtain statistical variance. Therefore, 1680 individual experiments were conducted by each variant, leading to a sum total of 16800 experimentations for all ten variants. The summarized results are presented in Section 5.4. The excerpt from the raw experiment results is given in Table 12. The full experiment results with the schedules can be found on CD (appendix A).

### 4.5 Chaos based DABC for QAP

The experimentation with CDABC solving quadratic assignment problem is presented in this section. The QAP problem dataset used for the experimentation was obtained from the OR Library [9].

### 4.5.1 Experiment setup

The experimentation were conducted on the Tesla server with the following specifications: Intel Xeon, CPU E5-2640 v2 running at 2GHz with 8 cores and 2GB of cache, hosted at the Media Research Lab [56].

The operating CDABC parameters are given in Table 13. All the parameters were kept fixed for all the simulations in order not to introduce any bias into the experimentations.

Table 13: Operating parameters of CDABC algorithm

| Parameter | Value |
| :--- | :--- |
| Food Source (FS) | 30 |
| Limit (food source) | 50 |
| Loop (Local Search) | 200 |
| Local search probability $\left(P_{L}\right)$ | 0.2 |
| Neighbourhood List $\left(N L_{L}\right)$ | 20 |
| Winning Neighbourhood List $\left(W N L_{L}\right)$ | $0.75 \times N L_{L}$ |
| Iterations | 100 |

QAP problem dataset on which the experimentation was conducted comprises seventeen different problem instances, with different flow dominance. For each problem instance, fifteen experiments were conducted. Therefore, 255 experiments were conducted for each CDABC variant, leading to a total of 1275 experiments. The example of the raw experiment output data is given in Table 14. The full experiment results with schedules can be found on CD (appendix A). The summary and analysis of results is presented in Section 5.5.

Table 14: CDABC for QAP, raw data excerpt.

### 4.6 Chaos based DABC for CVRP

The experimentation on CDABC for the CVRP problem was conducted under the same setup as the one for QAP. CVRP problem dataset, consisting of twelve different instances, was obtained from [110], with the range from 75 to 385 customers. Fifteen experiments were conducted on each instance, each variant having 195 simulations, leading to a total of 975 experiments.

The hardware configuration and CDABC operating parameters are described in the CDABC for QAP experimentation, Section 4.5. The analysis of results is presented in Section 5.6. The example from the experiment output is given in Table 17. The table contains first 3 results out of total 15 experiments conducted for each problem instance an each pseudo-random generator. Only costs and execution times of the problem solutions are shown. The full experiment results with schedules can be found on CD (appendix A).

### 4.7 Centralities Based ABC

The following section describes the experimentation conducted for two implementations of the centralities Based ABC, Adaptive $A B C 1$ and Adaptive $A B C$ 2. The standard test functions for continuous domain optimisation were used as a benchmark. Two sets of experiments were performed: First set of tests was run on small to medium scale problems with the parameter setting described in Section 4.7.2. The second set of tests improves upon the first one, fine tuning the parameters, running on medium to large scale problems as well. It is described in Section 4.7.4.

### 4.7.1 Experiment set 1: small and medium scale problems

The performances of Adaptive ABC 1 and Adaptive ABC 2 were compared against the performance of the original $A B C$ on small to medium scale problems, optimising the functions of the standard test set: Schwefel, De Jong 1, De Jong 3, De Jong 4, Rosenbrock's Saddle, Rastrigin, Griewangk, Sine Envelope Sine Wave, Ackley One, Ackley Two, Egg Holder, Michalewicz, Master's Cosine Wave, and Schekel's Foxhole, testing for 10, 20 and 30 dimensions.

### 4.7.2 Experiment set 1 setup

The experiments were conducted again on the server at Media Research Lab (MRL) at the VSB-Technical University of Ostrava, with the following CPU specifications: Intel Xeon CPU E5-2640 v2 with 2.00 GHz frequency.

For each of the algorithms, the experiments with population of $15,30,45$ and 60 solutions were made. The rest of the parameters were set as follows: the termination criterion was 100 generations. The network was evaluated after every 5th generation, with $40 \%$ lowest ranking solutions being recreated.

For every algorithm, problem, dimension and every tested value of the number of solutions ( $15,30,45$ and 60 ), 30 experiments were done to obtain the statistically valid sample. This makes up the total amount of $3 \times 168 \times 30=15120$ experiments. The statistical analysis of results is described in Section 5.7.1

### 4.7.3 Experiment set 2: small and medium scale problems

In this experiment set, the Adaptive $A B C 1$ and Adaptive $A B C 2$ are again compared to ABC , this time also on medium to large scale problems, optimising the functions of the same test set: Schwefel, De Jong 1, De Jong 3, De Jong 4, Rosenbrock's Saddle, Rastrigin, Griewangk, Sine Envelope Sine Wave, Stretch V Sine Wave, Ackley One, Ackley Two, Egg Holder, Michalewicz, Master's Cosine Wave, and Schekel's Foxhole, testing for 30, $40,50,75$ and 100 dimensions, in the allowed range of values between - 100 to 100 for each dimension, with 15 repetitions for each problem and dimension.

Moreover, the experiments on Adaptive ABC 3, as well as Adaptive ABC 3.b and 3.c were performed, to compare the effect of different centrality measure choice, as well as the effect of elitism incorporated in the pruning of the nodes logic. Five different versions of the complex network analysis incorporating modifications to the ABC algorithm are compared against the canonical variant.

### 4.7.4 Experiment set 2 setup

The platform used for testing is the same as in the first test set, described in 4.7.2, however, the parameter settings are changed. Extensive experimentation was performed to find the best parameter values of each algorithm. The resulting optimal parameter settings used for each algorithm are given in Table 20.

The excerpt from the raw experiment data comparing the results of ABC, Adaptive ABC 1, Adaptive ABC 2 and Adaptive ABC 3, 3.b and 3.c is shown in the Tables 22, 23, $24,25,26$ and 27. Due to the space limitations, only selected problems (Schwefel, De Jong 1, Masters Cosine Wave, Shekel's Foxhhole) are included in the tables; for each of these problems and each dimension, the first 3 outputs of 15 repeated experiments are shown. The solutions as well as full experiment results can be found on CD (appendix A). The statistically analysed data is presented in Section 5.7.2.

The next part of the experiment set compares the centrality measures employed in the ABC: Degree centrality, Closeness and Betweenness. The parameter settings used to compare effects of different vertex centrality choice on Adaptive ABC 3, Adaptive ABC 3.b, as well as Adaptive ABC 3.c, are given in Table 21.

The results for different centrality options are compared for each of the three algorithms separately. The conclusions are discussed in the analysis Section 5.7.2. The full output data for this experiment can be found on CD (appendix A).

## 5 Analysis of Results

### 5.1 NEH

The summarised results of the execution time in milliseconds of the ten instances on both platforms are given in Table 28. The first column gives the instance size, the second column is the average time for all ten instances of that particular instance size, the third column is the GPU computation time and the final column is the percentage relative difference (PRD) between the CPU and GPU based times computed as in Equation (69). These results were published in [73].

$$
\begin{equation*}
P R D=\frac{100 \times(C P U-G P U)}{C P U} \tag{69}
\end{equation*}
$$

For the smaller sized instances of $20 \times 5,20 \times 10$ and $20 \times 20$, the CPU version is faster. This is due to the overhead of the data transfer using the PCI Express bus between the CPU and GPU. However, from the medium sized problems ( $50 \times 5$ ) onwards, the GPU variant is faster for all instances. When analysing the PRD values, it becomes obvious that the relative difference is over 100 for all instances over $50 \times 20$, peaking at 518.75 for the $200 \times 10$ instance.

Analysing the OTS, the average CPU value is $\mathbf{6 2 1 5 . 3 3}$ and $\mathbf{1 4 0 6 . 6 8}$ for the GPU. This gives the average PRD for the twelve sets of $\mathbf{1 6 6 . 4 6}$.

For the ETS, the CPU average value is 186949 and 78808 for the GPU. The average PRD is 150.698 for the four data sets of the ETS.

Overall, the average value is 51398.8 for the CPU and 20757 for the GPU with the cumulative average PRD value of $\mathbf{1 6 2 . 5 2}$.

Therefore, for all the instance sizes barring the first three, GPU has faster execution times. However, statistical tests are needed to verify if there is significant improvement when utilising the GPU in respect to the execution times.

### 5.1.1 t-test analysis

Paired $t$-test comparison was done on the raw time values for each of the data instances. Therefore, the execution time for the ten instances in each set was compared pairwise for the CPU and GPU. The confidence level is $95 \%$ for these tests. The $t$-test results for each set are given in Table 29. Column one gives the instance size, column two is the $t$ value (the absolute value is shown), column three gives the $p$-value and the final column outlines the hypothesis. As the confidence level is $95 \%$, we check for $p$ values of less that 0.05 for a not equal hypothesis to hold true.

For the first three instances, the $p$ values are all negligible ( $p<0.05$ ), therefore the CPU is significantly faster than the GPU. For the $50 \times 5$ and $50 \times 10$ instances, the $p$ values are 0.067 and $0.152(p>0.05)$, therefore the hypothesis that the CPU and GPU implementations performances are not significantly different holds.

For all the remaining data sets the $p$ values are all negligible ( $p<0.05$ ), signifying that the GPU variant is significantly faster than the CPU. As this accounts for all the

Table 28: NEH results

| Instances | CPU | GPU | PRD |
| :---: | ---: | ---: | ---: |
| $20 \times 5$ | 0 | 1.64 | -100 |
| $20 \times 10$ | 0 | 2.79 | -100 |
| $20 \times 20$ | 2 | 4.77 | -58.07 |
| $50 \times 5$ | 11 | 8.19 | $\mathbf{3 4 . 2 6}$ |
| $50 \times 10$ | 20 | 15.09 | $\mathbf{3 2 . 5 2}$ |
| $50 \times 20$ | 39 | 16.72 | $\mathbf{1 3 3 . 2 9}$ |
| $100 \times 5$ | 81 | 30.21 | $\mathbf{1 6 8 . 1 1}$ |
| $100 \times 10$ | 180 | 57.25 | $\mathbf{2 1 4 . 4 2}$ |
| $100 \times 20$ | 665 | 112.96 | $\mathbf{4 8 8 . 7 3}$ |
| $200 \times 10$ | 1337 | 216.08 | $\mathbf{5 1 8 . 7 5}$ |
| $200 \times 20$ | 19719 | 4748.25 | $\mathbf{3 1 5 . 2 9}$ |
| $500 \times 20$ | 52530 | 11666.16 | $\mathbf{3 5 0 . 2 8}$ |
| $500 \times 50$ | 53394 | 19693.05 | $\mathbf{1 7 1 . 1 3}$ |
| $700 \times 20$ | 140090 | 48446.88 | $\mathbf{1 8 9 . 1 6}$ |
| $700 \times 50$ | 152692 | 71369.74 | $\mathbf{1 1 3 . 9}$ |

| Mean | 51398.8 | $\mathbf{2 0 7 5 7}$ | $\mathbf{1 6 2 . 5 2}$ |

larger problem dimensions, it verifies the hypothesis of this research. The final row of Table 29 gives the cumulative values for all the data sets, which again supports the claim that the GPU implementation is significantly faster than the CPU.

Table 29: NEH $t$-test results

| Instances | $\boldsymbol{t}$-value | $\boldsymbol{p}$-value | Hypothesis |
| :---: | :---: | :---: | :---: |

| $1000 \times 20$ | 171.23 | 0.000 | GPU |
| All | 7.125 | 0.000 | GPU |

### 5.2 2-opt algorithm

The results of 2-opt CUDA implementation compared to the sequential version are presented in Table 30. The first column is the instance size, the second column gives the average CPU execution time in milliseconds for the three instances of given size, the third column is the average GPU version execution time, the last column is the average PRD for the given dimension, defined in the equation 69 in the NEH results analysis section.

As the Table 30 shows, the PRD value is negative, i.e. in favour of the CPU implementation, for the first three dimensions. For the problems with more than 50 jobs, the PRD value is positive, in favour of the GPU, with the results improving with the dimension of the problem instance, especially for the problems with 100 jobs and more, where the improvement is always greater than $72 \%, 200$ jobs sized problems have the improvement of $92 \%$. It can be therefore stated that the GPU accelerated version is on average faster than the CPU version. However, the $t$-test is needed to prove whether this difference is statistically significant.

Because both algorithms return slightly different results, the analysis of the cost of solutions found by both of them is also included. It could be expected that the results for the GPU accelerated implementation would provide slightly improved results, however the Table 31 shows that this assumption was false. The relative difference is small in all cases, and it doesn't show any increasing or decreasing trend with the change of problem instance dimensions, it is closer to random oscillations.

To find out whether the difference of execution times is significant, the paired $t$-test

Table 30: 2-opt execution time

| Instances | CPU | GPU | PRD |
| :---: | ---: | ---: | ---: |
| $20 \times 5$ | 15.000 | 23.493 | -70.228 |
| $20 \times 10$ | 10.000 | 33.434 | -234.340 |
| $20 \times 20$ | 36.667 | 65.472 | -80.745 |
| $50 \times 5$ | 700.000 | 513.004 | 21.009 |
| $50 \times 10$ | 943.333 | 776.344 | 15.559 |
| $50 \times 20$ | 1730.000 | 1173.335 | 30.448 |
| $100 \times 5$ | 22260.000 | 5259.240 | 76.265 |
| $100 \times 10$ | 30043.333 | 5650.605 | 80.891 |
| $100 \times 20$ | 32336.667 | 8878.672 | 72.541 |

| $200 \times 20$ | 972536.646 | 67912.173 | 92.962 |

Table 31: 2-opt solution cost

| Instances | CPU | GPU | PRD |
| :---: | ---: | ---: | ---: |
| $20 \times 5$ | 726.500 | 733.400 | -0.959 |
| $20 \times 10$ | 1119.967 | 1110.700 | 0.864 |
| $20 \times 20$ | 1698.883 | 1710.667 | -0.666 |
| $50 \times 5$ | 1358.613 | 1356.640 | 0.157 |
| $50 \times 10$ | 1774.653 | 1745.273 | 1.620 |
| $50 \times 20$ | 2546.373 | 2569.380 | -0.893 |
| $100 \times 5$ | 2519.897 | 2533.560 | -0.538 |
| $100 \times 10$ | 2993.873 | 3030.857 | -1.258 |
| $100 \times 20$ | 3936.893 | 3891.687 | 1.143 |
| $200 \times 10$ | 5395.055 | 5409.933 | -0.277 |
| $200 \times 20$ | 6496.085 | 6524.793 | -0.444 |

was performed at $95 \%$ confidence level. Its results are presented in Table 32. The first column gives again the instance size, the second and third columns present the resulting t -value and p -value of the $t$-test, last column is the conclusion drawn from the $t$-test, with three possible values: CPU where the sequential version is better for given instance size, GPU where the parallel version performs better, or Equal, if there is no significant difference between the performances. For the problems smaller than 20 jobs, both algorithms perform at comparatively same speed for 5 machines, however the sequential implementation is significantly better for problems with 10 and 20 machines. Both sequential and parallel version are performing similarly for the problems with 50 jobs, however for problems with schedules greater than 100 jobs, GPU version performs significantly better than the CPU. The assumption taken from the PRD values is therefore confirmed, the parallel version is significantly faster than the sequential one.

Table 32: 2-opt $t$-test results

| Instances | $\boldsymbol{t}$-value | $\boldsymbol{p}$-value | Hypothesis |
| :---: | :---: | :---: | :---: |
| $20 \times 5$ | 2.5091 | 0.1288 | Equal |
| $20 \times 10$ | 4.3264 | 0.0495 | CPU |

| All | 2.7695 | 0.0093 | GPU |

### 5.3 Chaos based DABC for FSSLS

The experiment results summary for CDABC applied to the FSSLS is presented in this section. The average results obtained by the fifteen experiments are given in Table 33 for the Lozi data sets and Table 34 for the Dissipative data sets. The results were published in [71].

From the average results for the Lozi data sets, Tinkerbell has the lowest average values for 18 data instances. It also has the lowest collective average value of 10241.89. The second best performing variant is the Delayed Logistic with 10252.36 for the collective average value. Mersenne twister is the fifth best performing variant with 10359.71.

As in the Lozi case, Tinkerbell and Delayed Logistic are the two best performing variants in the Dissipative data sets. Tinkerbell obtains 12 best results, whereas Delayed Logistic obtains seven. For the collective average results, Tinkerbell has 14058.66 com-

pared to 14067.54 for the Delayed Logistic. Once again Mersenne Twister is the fifth best performing variant with the average of 14184.32.

### 5.3.1 t-test analysis

From the experimentations, the top four performing chaotic systems of Tinkerbell, Delayed Logistics, Burgers and Lozi together with the Mersenne Twister are compared pairwise for their performance. From the results it is obvious that the significant divergence of the results occurs from the medium to large data sets, therefore a comprehensive $t$ test analysis is conducted from the results of data set of instance 11 to instance 25 . As mentioned, 15 experiments have been conducted for each instance by each variant of the algorithm.

The $t$-test takes all the 15 results for each problem instance by the selected variant and conducts a pairwise comparison. The $t$ and $p$ values for the paired $t$-test are given in Table 35 for the Lozi test instances and Table 36 for the Dissipative test instances.

The $t$-tests were conducted at a $95 \%$ confidence level, so all pairwise compared variants, which have a value of $p$ of less than 0.05 can be interpreted as being significantly different from each other. From the obtained $t$-test results (Table 37) all the variants are significantly different from each other apart from Mersenne Twister and Lozi Map. Based on these results, it can be inferred that the hierarchy of the five best performing variants based on average performance are Tinkerbell, Delayed Logistic, Burgers, Lozi and Mersenne Twister for the Lozi data sets. For the Dissipative data sets the best five variants are Tinkerbell, Delayed Logistic, Lozi, Burgers and Mersenne Twister.

The basic premise of this research is therefore achieved as it has been shown that a number of different chaotic systems improves DABC, under the same operating parameters.

### 5.3.2 Comparison with Enhanced Differential Evolution

An algorithm comparison is done with the chaos driven Enhanced Differential Evolution $\left(\mathrm{EDE}_{\mathrm{C}}\right)$ algorithm of [20]. EDE algorithm is an extension of the canonical DE algorithm, with backward/forward transformation structure and embedded local search. EDE $_{C}$ has been shown to significantly improve upon EDE. The comparison between $\mathrm{EDE}_{\mathrm{C}}$ and CDABC for the Lozi data sets is given in Table 38. In this case, the Tinkerbell variant of CDABC $\left(\mathrm{CDABC}_{T}\right)$ is chosen as it is the best performing.

Four different parameters are presented; minimum, maximum, average and execution time for each instance class. The instance class here refers to the grouping of the problems according to size; $10 \times 5,20 \times 10,50 \times 25,75 \times 30$ and $100 \times 50$.

The parameter of most interest is the average, as it presents the overall performance of the algorithm. $\mathrm{CDABC}_{\mathrm{T}}$ has three better class averages of size $20 \times 10,50 \times 25$ and $100 \times 50$, whereas $\mathrm{EDE}_{C}$ performs better for the $10 \times 5$ and $75 \times 30$. Also, $\mathrm{EDE}_{C}$ has the better cumulative average of 10435.73 compared to 10917.93 . However, it is quite obvious that the bias of the $75 \times 30$ ( 8297.76 against 11561.49) data class greatly influences the cumulative average in $\mathrm{EDE}_{\mathrm{C}}$ favour.

The comparison results between $\mathrm{EDE}_{\mathrm{C}}$ and $\mathrm{CDABC}_{T}$ for the Dissipative data sets are given in Table 39. Apart from the $10 \times 5$ data class, $\mathrm{CDABC}_{\mathrm{T}}$ obtains better results for all the remaining data classes, in addition to the cumulative average value of 14058.74 against 14152.97 .

Therefore, it can be stated that $\mathrm{CDABC}_{\mathrm{T}}$ is a better performing algorithm compared to $\mathrm{EDE}_{\mathrm{C}}$ for the non-idling problem.

Table 39: Comparison of CDABC with $\mathrm{EDE}_{\mathrm{C}}$ for Dissipative Non-Idling results

|  | EDE $_{\mathbf{C}}$ |  |  |  | CDABC $_{\boldsymbol{T}}$ |  |  |  |

### 5.4 Chaos based DABC for FSSNW

The average results obtained by the 140 experiments of each problem data class are given in Tables 40 and 41. From the results, it can be concluded that the two most promising results are from the Tinkerbell and Delayed Logistic map systems. Tinkerbell has the best average results for the $20 \times 5,20 \times 10,100 \times 5,100 \times 10,100 \times 20,200 \times 10,200 \times 20$ and $500 \times 20$ data sets. Delayed Logistic obtains the best results for the remaining data sets of $20 \times 20,50 \times 5,50 \times 10$ and $50 \times 20$ data sets. Additionally, it obtains better cumulative average value and standard deviation. The results were published in [74].

### 5.4.1 t-test analysis

The paired $t$-test is conducted pairwise on all the different variants of CDABC. All the raw results were used for the computations, implying that for each variant, all 1680 results were pairwise compared. The results comprising of the $t$ and $p$ values is given in Table 42. For all the $t$-test comparisons, the $p$ value is compared to a $95 \%$ confidence level. In terms of significance, it can be postulated from the results that all variants of CDABC are significantly different. Therefore, it becomes obvious that the order of the best performing variants is given as Delayed Logistic, Tinkerbell, Burgers, Lozi, Mersenne Twister, Ikeda, Dissipative, Arnold Cat, Sinai and Henon Map.

Table 40: Summarised results for Mersenne Twister, Arnold Cat, Burgers, Delayed Logistic and Dissipative Maps

### 5.5 Chaos based DABC for QAP

The following text presents the statistical analysis of experiment results. Three different statistical measures of importance; cumulative average, standard deviation of the results and average time, were calculated for each problem instance. These measures for the DABC with Mersenne Twister ( $\mathrm{DABC}_{\mathrm{MT}}$ ), $\mathrm{CDABC}_{\mathrm{B}}, \mathrm{CDABC}_{\mathrm{DL}}, \mathrm{CDABC}_{\mathrm{L}}$ and $\mathrm{CDABC}_{\mathrm{T}}$ are given in Table 44. Results of QAP experiment were published as part of [75].

According to the results, the $\mathrm{CDABC}_{\mathrm{T}}$ is the best performing variant of the CDABC algorithm. Of the seventeen instances, it has the better average for thirteen instances. These are spread over the different problem instances of bur, kra, tai and chr instance types in the dataset. $\mathrm{CDABC}_{\mathrm{B}}$ map has one better average for the bur26e instance, while $\mathrm{CDABC}_{\text {DL }}$ has three better average instances of kra30a, bur 26 b and tai40b.

In terms of cumulative average values of all the seventeen instances, $\mathrm{CDABC}_{\mathrm{T}}$ has better cumulative average of 151351762.78 and the smallest cumulative standard deviation of $1.08 \mathrm{E}+06$. In terms of execution time, $\mathrm{DABC}_{\mathrm{MT}}$ has the lowest execution time of 0.67 seconds compared to 2.241 seconds for the $\mathrm{CDABC}_{\mathrm{T}}$.

### 5.5.1 $\quad$ t-test analysis

Paired $t$-test analysis was conducted on the raw data for the different variants in order to analyse if there is any significant difference between them. All 255 instances for the different variants were pairwise compared and the respective $t$-value and $p$-value was calculated. The $t$-test results are given in Table 43.

The variants were tested at $95 \%$ confidence level, and from the results only the $\mathrm{CDABC}_{\mathrm{B}}$, $\mathrm{CDABC}_{\mathrm{DL}}$ and $\mathrm{CDABC}_{\mathrm{DL}}, \mathrm{CDABC}_{\mathrm{T}}$ variants are not significantly different. All the other variants are significantly different pairwise.

Based on these results, we can confidently state that chaos maps significantly improve on the Mersenne Twister PRNG in DABC algorithm. In terms of hierarchy obtained from the cumulative average values, the order can be given as $\mathrm{CDABC}_{\mathrm{T}}, \mathrm{CDABC}_{\mathrm{DL}}$, $\mathrm{CDABC}_{\mathrm{B}}, \mathrm{CDABC}_{\mathrm{L}}$ and $\mathrm{DABC}_{\mathrm{MT}}$.

### 5.6 Chaos based DABC for CVRP

The analysis of experiment results for CDABC solving CVRP problem was performed in the same manner as that of QAP, found in Section 5.5. The same three attributes; average, standard deviation and execution time, were obtained for each problem instance. The tabulated results are given in Table 46. These results were published as part of [75]. For the CVPR problem, $\mathrm{CDABC}_{\mathrm{T}}$ is the best performing variant for all the problem instances, with $\mathrm{CDABC}_{\mathrm{B}}$ the second best performing.

In terms of cumulative average values, $\mathrm{CDABC}_{\mathrm{T}}$ has the best cumulative average value of 6826.437 and standard deviation of 112.973 . $\mathrm{DABC}_{\mathrm{MT}}$ once again has the lowest execution time of 1.1195 seconds.

### 5.6.1 t-test analysis

Paired $t$-test was again applied to the different algorithms in order to ascertain if there was significant difference between each two of the variants. The $t$-test results are given in Table 45. At $95 \%$ confidence level, only the $\mathrm{CDABC}_{\mathrm{B}}, \mathrm{CDABC}_{\text {DL }}$ maps are not significantly different, whereas all the other variants are significantly different pairwise. Through the analysis of the cumulative values in Table 46, we can state that the order of best performing variants is $\mathrm{CDABC}_{\mathrm{T}}, \mathrm{CDABC}_{\mathrm{B}}, \mathrm{CDABC}_{\mathrm{DL}}, \mathrm{CDABC}_{\mathrm{L}}$ and $\mathrm{DABC}_{\mathrm{MT}}$.

Table 45: $t$-test results for the CVRP problem instances

### 5.7 Centralities Based ABC

This part presents the statistical analysis of the results of experiments conducted on the Centralities Based ABC, described in Section 4.7. The first part contains the analysis performed on the first test set (described in Section 4.7.1), with mean, standard deviation and execution time for each problem and dimension. These results are published in [72]. The second part consists of results of the second test set (presented in Section 4.7.3), with the same statistical summary for each problem and its selected dimension, together with the $t$-test analysis of differences between algorithms. Finally the results of three selected vertex centrality measures are statistically compared.

### 5.7.1 Analysis of experiment set 1

The experiment results are shown in Tables 47, 48 and 49. Each table contains data for one problem dimension setting ( 10,20 and 30 variables). Each table row contains experiment data for ABC, Adaptive ABC 1 and Adaptive ABC 2: mean of the best solution values found for the problem of given dimension, average standard deviation of the best solution costs, and the average time needed by the algorithm, calculated over the results with different number of solutions settings ( $15,30,45$ and 60 number of solutions). The best value of each experiment is marked in bold for visual comparison of the algorithm results.

For problems of size 10, ABC has found best values for 5 problems, Adaptive ABC 1 has better results for 6 problems, Adaptive ABC 2 has found only 3 best values. The average of standard deviation for all problems is better for ABC, with the value of 718.210, the second best for Adaptive ABC 1, with the value of 1123.011, and worst for Adaptive ABC 2, 1574.011.

With the problems size 20, ABC has 4 best values, Adaptive ABC 1 has 6 best values again, while Adaptive ABC 2 has 4 best values. The total average of standard deviations is best for Adaptive $A B C 1$, with the value of 1539920.718 , $A B C$ has second best aver-

age standard deviation value of 2854647.978 , Adaptive ABC 2 has the largest standard deviation of 4727753.998.

For the problems size 30, ABC has 5 best values, Adaptive ABC 1 has only 1 best value, while Adaptive $A B C 2$ has 7 best values. Average standard deviation of Adaptive $A B C 1$ has the lowest value of the three algorithms, with the value of 215051695.164 , the second best is ABC again, with the value of 363408745.264 , and the worst value holds Adaptive ABC 2, with 560248294.495.

For the overall analysis, on the 10 and 20 sized problem, Adaptive ABC 1 has better performance than both ABC and Adaptive ABC 2 . However, for the larger 30 dimension problem, Adaptive ABC 2 has a marked better performance than Adaptive ABC 1. We can conclude that the ensemble population is more efficient for higher dimensional problems.

### 5.7.2 Analysis of experiment set 2

The results for the second experiment set, are presented in Tables 50-58. Each table contains results for one problem dimension ( $10,20,30,40,50,75,100$ ) reached by ABC and five centralities based ABC modifications: Adaptive ABC 1, 2, 3, 3.b and 3.c. Each row contains data for one of the test functions, the last row contains summary: the average for the dimension. The mean of the costs of best solutions found, the standard deviation of costs, and the average execution time are presented for every algorithm. Table 59 shows the average values across all dimensions for each problem, with the last row showing total mean of each algorithm.

From these results, it can be observed that the Adaptive ABC 3.b has the best overall average. The 2nd best average was achieved by the Adaptive ABC 3.c. The Adaptive $A B C$ 3, Adaptive $A B C 1$ as well as Adaptive $A B C 2$ have all worse average than the original ABC. Comparing by the individual testing problems, The Adaptive ABC 3.b is better than the original $A B C$ in ten out of total 15 problems. The Adaptive ABC 3.c is better in nine problems, Adaptive $A B C 3$ in three problems. The Adaptive ABC 1 improves upon $A B C$ in only two of the problems, whereas Adaptive $A B C 2$ gives four better results than $A B C$. The results suggest that the algorithms are capable of finding the solutions of different quality. This hypothesis is confirmed by the pairwise comparison of the algorithms using $t$-test, presented in Table 61. Accordingly, all the algorithms results are statistically significantly different at $95 \%$ confidence level, apart from the Adaptive ABC 1 and Adaptive ABC 3. Considering this analysis, it can be stated that the Adaptive ABC 3.b and Adaptive $A B C$ 3.c both significantly improve upon the original $A B C$ algorithm, as well as the other centralities based $A B C$ versions, showing the necessity to incorporate the elitism in the low centrality nodes removal logic.

Comparing the standard deviations of results, the least varied outcomes are provided by Adaptive ABC 1. The 2nd is Adaptive ABC 3, followed by ABC, Adaptive ABC 3.c, 3.b with Adaptive ABC 2 coming last. This is nearly the reversed order with respect to the overall best mean values. However, comparing by problem, none of the algorithms improves upon the original ABC standard deviation in more than $50 \%$ of the problems, nor is it worse in more than $60 \%$ of the problems.

The execution times comparison shows that the fastest running algorithm was the Adaptive ABC 2, followed by Adaptive ABC 3, 3.b, 3.c and 1, with the ABC being the slowest. This is however probably heavily influenced by the settings, such as the number of generations between complex network analysis and subsequent nodes removal and recreation, the cut-off ratio parameter, defining how many nodes are removed, as well as the original ABC parameter limit, defining how many attempts are made to improve the solution, before it is removed from the population and randomly reinitialized.

The statistical analysis of the results for different centrality measures (degree, closeness and betweenness) is presented in the following text. The Tables $62-64$ show the overall averaged results across all the dimensions for each problem in the row, the different vertex centralities are arranged in the columns. Each Table contains data for one of the algorithms of Adaptive $\operatorname{ABC}$ 3, Adaptive $A B C$ 3.b and Adaptive $A B C$ 3.c separately. Again the average best solution cost, standard deviation and the average execution time are presented.

For the Adaptive ABC 3, the overall best average value is achieved by the closeness centrality. For the Adaptive $A B C$ 3.b, the best average value is obtained by degree centrality, in the case of Adaptive ABC 3.c, the closeness centrality achieves the best average result again. The second best was the degree, closeness and betweenness for the discussed algorithms, respectively. Comparing the differences by the problem, the closeness centrality holds the best average results in seven out of 15 problems, the degree centrality in five and the betweenness in three problems. For the Adaptive ABC 3.b, the degree centrality has six best values, while the closeness reaches only three bests, with betweenness achieving six bests. In the case of Adaptive ABC 3.c, the closeness finds eight best values, the degree four and the betweenness only three best values. Neither these results, nor the comparison by the problem dimension, suggest significant difference, which is again confirmed by the $t$-tests, presented in Table 65 (separately for each algorithm). None of the centrality measures shows statistically significant difference compared to the other.

## 6 Conclusion

At the centre of interest of this thesis were the heuristics employed in solving the combinatorial optimisation problems, with the emphasis on scheduling problems. The core objective was to improve the performance of state-of-the art existing algorithms. This was attempted in several ways.

In the first part, deterministic heuristics were considered: NEH algorithm as one of the most popular constructive heuristics and the 2 -opt algorithm as an improvement heuristic for permutative flowshop scheduling problem. The parallel implementation using the CUDA platform was developed for each of them.

Wide scale experimentation was performed for NEH solving permutative flowshop with makespan criterion, using the newly created data set based on the original Taillard data sets, which became a standard benchmark problem instances for the optimisation algorithms performance assessment, termed the extended Taillard data sets. The problem instances of size varying from $20 \times 5,20 \times 10,20 \times 20,50 \times 5,50 \times 10,50 \times 20,100 \times 5,100$ $\times 10,100 \times 20,200 \times 10,200 \times 20$ to $500 \times 20$ (the original Taillard data set) and $500 \times 50$, $700 \times 20,700 \times 50$ up to $1000 \times 20$ (the extended Taillard data set), 10 instances for each size, which makes up total of $16 \times 10=160$ unique instances, were evaluated by the original sequential and the newly developed parallel version of NEH, and the execution times compared. The statistical analysis of results using PRD as a measure has shown that the parallel implementation of NEH achieved the statistically significant speed-up over the sequential version for all instances greater than $50 \times 10$, with the best results of $6.18 \times$ speed-up for the instance size $200 \times 10$, and the average speed-up of $2.62 \times$. It can be therefore stated that there is a potential for speed-up.

Further development of this algorithm is two fold: the parallel implementation can be further optimised by fine-tuning the CUDA settings (launch configuration), as well as improved memory mapping using better suited cache types, supporting wider range of CUDA enabled GPU generations. The naive implementation of flow shop makespan evaluation could be also parallelised, achieving further acceleration. As the second aspect, the NEH heuristic would be used to provide the initial solution for the selected evolutionary algorithm (its CUDA based implementation), thus increasing the chance of finding better quality optima in addition to reducing the overall time required for the search.

The experimentation of somewhat reduced extent was performed for the 2-opt algorithm, solving again permutative FSS with makespan criterion, using only subset of standard Taillard data sets, the problem instances from $5 \times 20$ to $20 \times 200$, evaluating the three instances for each of the sizes, hence performing 33 experiments in total. Both the execution times and the optimal solutions found were compared between sequential and parallel version. No significant difference was proved between the quality of solutions, on the other hand, the execution time was again significantly reduced, starting from the instances of the size $100 \times 5$, with the best speed-up achieved for the instances size $200 \times 10$ and $200 \times 20$, yielding $1.92 \times$ acceleration over the sequential version.

For the future goals, most of the same approaches as for the NEH can be employed. Further optimisation of the launch configuration and the improved memory mapping
could be used to achieve better results, together with the parallel flowshop evaluation. The broader support of compute capabilities could also be included. The accelerated version of 2-opt can then be also used to support the parallel implementation of an evolutionary algorithm, as it is the standard practice of embedding the local search into EA's to further improve the solutions generated by EA's search mechanisms.

In the second part, the effects of stochasticity on the selected combinatorial optimisation problems solving EA, the DABC algorithm, were explored. The standard PRNG, Mersenne Twister, was replaced by the PRNG based on the outputs of nine different chaotic piecewise linear one-dimensional maps. These nine unique chaos-based PRNGs then formed nine different modified versions of $\operatorname{DABC} ; \mathrm{CDABC}$, whose performances were empirically assessed and compared against one another.

In the first stage of research, all of these algorithms performances were evaluated on the lot-streaming flowshop scheduling problem with setup times and no-idle constraint, using DABC with Mersenne Twister as a reference. Two unique CPRNG generated datasets, the Lozi data set using Lozi chaotic map, and the Dissipative data set using Dissipative chaotic map as CPRNG, were used for the experimentation. Each of them contained problem instances of 10 jobs $\times 5$ machines, 20 jobs $\times 10$ machines, 50 jobs $\times$ 25 machines, 75 jobs $\times 30$ machines and 100 jobs $\times 50$ machines, 5 instances of each size, making up the total of 25 unique instances in each of the two data sets. For both data sets, 15 repeated experiments were performed, forming the total of $2 \times 25 \times 15=750$ experiments for each algorithm variant, $10 \times 750=7500$ experiments in total. It was shown that the Tinkerbell, Delayed Logistic, Burgers and Lozi map yielded significantly better results than the original DABC with Mersenne Twister both for Lozi data sets and Dissipative data sets. To sum up the results, the five best performing PRNGs for Lozi data sets were: Tinkerbell, Delayed Logistic, Burgers, Lozi map and Mersenne Twister. For the Dissipative data sets, the ordering by performance was as follows: Tinkerbell, Delayed Logistic, Lozi, Burgers map and Mersenne Twister.

In the second stage, the CDABC variants were employed to solve the flowshop with no-wait constraint (zero-intermediate storage), using standard Taillard data set as a benchmark. For each of the 12 instance sizes, 10 instances per size, 14 repeated experiments were performed to obtain statistically valid sample, making the total of $12 \times 10 \times 14=1680$ experiments per variant, $10 \times 1680=16800$ experiments altogether. Again, statistically significant improvements were achieved. The order of the five best performing variants was as follows: Delayed Logistic, Tinkerbell, Burgers, Lozi, Mersenne Twister. This has shown that that the top four CDABC variants outperform Mersenne Twister on yet another problem, furthermore using the data sets generated using the standard PRNG as well, hence the previous results achieved in solving FSSLS instances generated by chaosbased PRNGs were not entirely problem and stochasticity specific.

Finally, the four best performing chaotic maps from previous experiments were used to solve the problems other than those in the manufacturing field, the capacitated vehicle routing problem and the quadratic assignment problem, solving the problem instances from the OR Library and the Taillard CVRP problem instances, respectively.

The QAP data set contains 17 problem instances. For each of them, 15 experiments
were performed, providing the total of $17 \times 15=255$ experiments per algorithm variant, $5 \times 255=1275$ experiments in total. CVRP range from 75 to 385 customers, consisting of 13 problem instances. For each of them, 15 experiments were performed, giving the total of $13 \times 15=195$ experiments per algorithm variant, $5 \times 195=975$ experiments in total.

In both cases the statistically significant improvement was obtained. The order of the best performing algorithms is as follows: Tinkerbell, Delayed Logistic, Burgers map, Lozi map, Mersenne Twister for QAP problem instances; Tinkerbell, Burgers map, Delayed Logistic, Lozi map, Mersenne Twister for the CVRP problems. This comes at a cost of slightly decreased speed of CDABC variants, compared to the DABC with Mersenne Twister.

The future development plans include the exploration of different types of chaotic systems used as the CPRNGs, for instance the coupled maps, as well as further applications of CPRNGs in solving difficult combinatorial optimisation problems, since the superiority was empirically proven.

For the last part of the thesis, the complex networks properties, namely vertex centrality measures were used to modify the ABC algorithm, providing the basis of selfadaptive mechanism, which replaces the solutions that don't contribute to the population development with the new ones. Three different centralities: weighted degree, closeness, betweenness were implemented inside five different approaches to the design of such algorithm: Adaptive $A B C$ 1, Adaptive $A B C$ 2, Adaptive $A B C$ 3, Adaptive $A B C$ 3.b and Adaptive $A B C$ 3.c. Both Adaptive $A B C 1$ and 2 were implemented using all three centrality measures - Adaptive ABC 1 splitting the population conceptually into three parts for the purpose of vertex centrality evaluation only, Adaptive ABC 2 using ensemble approach creating three separated populations, each with its own network and assigned centrality measure. Adaptive ABC 3 used centrality measure type provided as parameter, enabling the assessment of the effect of different centrality measures. This was extended by incorporation of elitism, always keeping certain ratio of best quality solutions in the population, in the algorithms Adaptive ABC 3.b and Adaptive ABC 3.c.

The functions of the standard test set for continuous optimisation were used for experimentation: Schwefel, De Jong 1, De Jong 3, De Jong 4, Rosenbrock's Saddle, Rastrigin, Griewangk, Sine Envelope Sine Wave, Ackley One, Ackley Two, Egg Holder, Michalewicz, Master's Cosine Wave, and Schekel's Foxhole, with the dimensions of 10, 20,30 for the first experiments set; the same functions plus Stretch V Sine Wave for the second experiments set with the dimensions of $10,20,30,40,50,75,100$.

The first experiment set was conducted to compare the ABC, Adaptive ABC 1 and Adaptive ABC 2. Thirty experiments were performed for each problem and dimension, trying the different number of solutions in the population: $15,30,45$ and 60 . This makes up together 14 problems $\times 3$ dimensions $\times 4$ number of solutions settings $\times 30=5040$ experiments for each algorithm, $3 \times 5040=15120$ experiments in total.

The second experiment set was extended with the Adaptive ABC 3, Adaptive ABC 3.b and Adaptive ABC 3.c. All five algorithms were compared against the standard ABC. Fifteen repetitions were done for each problem and each dimension, resulting in 15 problems $\times 7$ dimensions $\times 15=1575$ experiments for each algorithm. Another experimen-
tation on this set was conducted to compare the effects of different centrality measures against one another, using the same setting described above for degree, closeness and betweenness, in each of Adaptive $A B C$ 3, Adaptive $A B C$ 3.b and Adaptive $A B C$ 3.c, comparing the results separately. This makes up $1575 \times 3=4725$ experiments for each of the latter algorithms, hence 14175 experiments in total.

For the first experiment set, the Adaptive ABC 2 tends to be better for the problems with 30 variables, reaching the best values (in comparison with both ABC and Adaptive $A B C 1$ ) in 7 out of 14 problems. On the other hand, the Adaptive ABC 1 tends to be better than Adaptive ABC 2 for the dimensions 10 and 20, however, the results are comparable with the standard ABC algorithm in all cases.

In the second experiment set, where the parameters were tuned, the statistically significant difference was proven for all of the six tested algorithms pairwise, except for the Adaptive ABC 1 and Adaptive ABC 3. The order of the algorithms sorted by the average performances is following: Adaptive ABC 3.b has the best overall average. The 2nd best average was achieved by the Adaptive ABC 3.c. The standard ABC follows with the Adaptive ABC 3, Adaptive ABC 1 and Adaptive ABC 2 having the worst overall average. Comparing by the individual problems separately, The Adaptive ABC 3.b is better than the original $A B C$ in ten out of total 15 problems. The Adaptive ABC 3.c is better in nine problems, Adaptive ABC 3 in three problems. The Adaptive ABC 1 improves upon $A B C$ in only two of the problems, whereas Adaptive $A B C 2$ gives four better results than $A B C$. It can be therefore concluded, that the versions with elitism perform significantly better on average, and that in accordance with no free lunch theorem, each of the algorithms can be potentially useful at least in subset of problem classes. The comparison of measure types didn't find any significant differences, the performance of all of the three centralities was similar.

For the future path, since the selected centralities performed similarly well for all of the algorithm variants, it would be sufficient to retain only one of them. Different modifications to the existing algorithms could be produced, incorporating more sophisticated complex network properties and different centrality measures (Katz Centrality for example) to asses the nodes influence in the network. It is obviously necessary to incorporate the elitism into such algorithms, in order to retain the good quality solutions in the population and not to randomize the search to a large extent. Different schema of the least influential solutions replacement could also be used, for instance creating the new solutions in the proximity of the already found good ones, thus accelerating the convergence. Finally, this approach would be implemented in a discrete evolutionary algorithm which also forms complex networks through the course of its iterations, to support solving of the combinatorial optimisation problems.

## A CD with experiment data and source codes

The accompanying CD contains the electronic form of this document, experiment outputs and the source codes with short manuals for each of the programs. The structure of CD is following:

- Code :

Source codes of each of the programs in separate folder.

- ExperimentData :

Experiment outputs in separate folders.

- Manuals :

Manuals, readmes and examples of usage.

- Text :

Electronic form of this thesis, thesis.pdf.

[^0]:    Input:
    $N S$ : number of solutions in the population
    NGenNumber : number of generations for network creation
    CutoffRatio : ratio of low centrality ranking nodes to be recreated
    MeasureType : centrality measure type to be used EliteRatio : ratio of the best cost
    solutions to always keep in the population

    Generate initial population Population of NS solutions
    Initialise the network Network
    initialise generation counter GenCounter
    initialise network generation counter NGenCounter
    while max generation not reached do
    send Employed bees and update the Network
    send Onlooker bees and update the Network
    send Scout bees
    memorize the best solution
    if NGenCounter $==$ NGenNumber then
    calculate centrality MeasureType of all NS nodes
    nodesByCentrality $\leftarrow$ sort nodes by the centrality ranking in ascending order
    nodesByCost $\leftarrow$ sort nodes by corresponding solutions' fitness value in
    ascending order
    for $i=1$ to $N S \times$ CutoffRatio do
    node $\leftarrow$ nodes ByCentrality[i]
    if node not in nodesByCost[1 to NS $\times$ EliteRatio] then
    replace the solution belonging to the node by new one
    end
    // else skip node
    end
    reset Network and NGenCounter
    end
    increase GenCounter
    increase NGenCounter
    end
