requirements for the Degree of
Master in City Flanning

## AESTRACT

The economic difficulties of the $1970^{\circ} 5$, the recessions of the 1980's, and the current $1983-85$ period of economic recovery all raise serious questions about the future of the U.S. economy and the plight of the American worker. Recently, the industrial policy debate has increased concern and scholarship about the relationship between changing employment trends and the process of industrial restructuring.

The objective of this thesis is to discern whether the structural changes which have been occurring in the economy over the past ten to fifteen years have affected the employment shares of women and minority workers across industries. This task was accomplished by analyzing changes in the employment concentrations of these workers by industry using disaggregated data obtained from the 1980 and 1970 Census Fublic Use tapes. A matrix reflecting changing employment concentrations was produced for the ten year interval.

The findings of this research illustrate a worsening labor status for women and minority workers in the U.S. labor market. The data shows that these workers tend to be employed in higher concentrations than white males in distressed-restructuring and deindustrializing--industries and therefore are directly affected by the economic condition of the industries and the economy as a whole. This finding raises questions about the future of our labor market which must be addressed if economic and social equality for these groups-women and minorities--is to be realized.

## CHAETEE ONE

## INTRODUCTION

A structural transformation--a restructuring of capital and 1 abor-has been occurring in the U.S. economy over the past ten to fifteen years. The economic difficulties of the 1970's, the recessions of the $1980^{\circ} 5$ and the current $1983-85$ period of economic recovery, all raise serious questions about the future of the U.S. economy and the plight of American workers. National unemployment continues to rise, the incidence of poverty is increasing: and the standard of living for the majority of American families is falling. These economic hardships: however: have not been equally distributed throughout the population, rather they have been disproportionately experienced by workers in the Snowbelt regionss minorities everywhere, female heads of households, blue-collar workers in basic industries, youth of all ages, and the like.

The economic crisis caused by structural changes in the U.S. economy has had measurable effects on the employment patterns of women and minority workers. These groups: especially minorities tend to be concentrated in the sectors-manufacturing and consumer services--and within occupations-1 aborers and operatives--which have been hit hardest by
industrial restructuring. [Squires: P. 153]

A number of economic trends indicate the presence of structural changes. Shifts in capital investment, the spatial decentralization of the worlfplace, the higher growth rate of the service sector relative to manufacturing, and labor displacing technology all characterize the current restructuring occurring in the American economy. Cases have been made which attribute these changes to an increase in foreign imports and to the systematic disinvestment in basic industries--deindustrialization--as primary causes in eroding U.S. industrial employment.

Declining levels of employment in basic industries, ie. steel, automobiles, textiles, and apparel have become more and more acute over time. Between 1979 and 1982 U. S. Employment in manufacturing declined 10.4 percent, the largest drop in postwar history. [Lawrence: p. 1] Studies in this regard have been undertaken by Robert $Z$. Lawrence and Charles Schultze of the Brookings Institution which disclaim heightened levels of international trade and deindustrialization as causes for the current economic crisis. These studies, however, are based on aggregate analyses of the manufacturing sector and do not necessarily reflect differing employment patterns amongst industries within the sector.

Fegardless of whether deindustrialization is a reality or a myth, America"s basic manufacturing industries are currently and have been for the past decade sustaining substantial employment losses. The evidence suggests that it is in fact structural changes as distinct from business cycle fluctua-

```
tions which are causing these problems. The shift in the U.S.
economy from a primarily "goods-producing" to a "service-
producing" nation also has been attributed as a contributing
factor in affecting changes in the composition of the labor
force and the distribution of wort:ers across industries.
```

```
While the transformation to a service economy seems
to have been fruitful in the sense of creating numerous
employment opportunities in large numbers: it appears
also to have contributed greatly to creating a more
divided labor market structure characterized by a
polarization of earnings and by systems of work in which
workers at the bottom of the structure face restricted
opportunities for advancement. [Noyell: Stanback: P.2]
```

The expansion of employment in the service sector may not sufficiently replace the type of job opportunities lost due to the decline in manufacturing employment. An economic dislocation of specific groups of workers previously employed in manufacturing may take place concomitantly with the growth of the service sector.

Manufacturing industries have been traditionally an important resource of employment, providing jobs with higher-than-average wages and good 1 abor market opportunities and experiences to lesser skilled, uneducated individuals not elsewhere available. The substantial loss of manufacturing employment is expected to fall disproportionately on minorities as well as place women in a disadvantaged position in the labor market.

Doreen Massey in her research on job losses and economic dislocation draws a parallel between industrial restructuring and social restructuring. She writes;

And industrial restructuring is a process of class restructurirg: it is one of the mechanisms by which the social structure is re-shapeds social relations changed and the basis for policital action broten down or reconstructed. [Massey. P. 74]

Viewing industrial change as a process of social change serves to emphasize the importance of employment and occupuational status in determining socioeconomic position in this society. To this extent, the changing industrial or sectoral concentrations of women and minority workers into the lower segments of the 1 abor market where the jobs are characterized by low wages, high turnover, high unemployment, few benefits and little security raises questions as to the future employability of these groups. If women and minority worters are disproportionately concentrated and segregated into dis-tressed-rrestructuring and deindustrializing--industries how will this bear on the future status--social and economic--of these groups. These implications will be addressed in the concluding chapter of this thesis.

The major focus of this research will be to quantitatively describe the occurrences and proportions in which women and minorities appear in the labor market. The product of this investigation will be a matrix reflecting changes in employment patterns by industry for white and nonwhite, male and female, white male and female, nonwhite male and female workers between 1980 and 1970 . The task is to relate the measurable changes in the composition and distribution of these groups within and across industries to the current industrial restructuring.

This thesis will use a disaggregated sectoral analysis to uncover the impact of structural changes on the labor market over the ten year interval. Data obtained from the 1980 and 1970 Census Fublic Use Tapes will be used to estimate the proportions of women and minorities employed within and across each industry. Attention will focus on industries whose employment growth flattened out in the $1970^{\circ} \mathrm{s}$, as contrasted to growth industries, in order to develop hypotheses and explainations which address the employment patterns of women and minority workers in the midst of structural transfor-mations--industrial restructuring and continued economic change. The analysis of these employment patterns over the ten year time interval will appear in Chapter Three.

This work is part of a larger research effort being conducted by Professors Bennett Harrison of the Department of Urban Studies and Planning at MIT and Earry Eluestone of the Social Welfare Research Institute at Boston College. The broader research agenda will examine the effects of structural changes within sectors and occupuations on labor market conditions and labor force concentrations; and the changing distribution of jobs and wages across the economy. Like this research, emphasis will be placed on disaggregated data to relate changes in emplayment shares by industry with industrial restructuring.

Over the last decade, it has become more obvious that if women and minority workers are to better their respective positions in the labor force and in society, they must champion political forces behind their cause. All too often,

```
the economic inequalities of the labor market mirror the
inequities of society. The economic democracy and industrial
policy arguments provide a forum to debate these issues. The
importance of research of this nature is that it documents the
degree to which women and minorities are dislocated by job
losses due to deindustrial-ization and affected by new job
opportunities created in restructuring industries. The
concluding chapter will look at the need for women and
minorities to participate in the debate on industrial policy
and its implications in the advent of structural
transformations occurring in our economy.
```

## Method of Eesearch:

Sample census data has collected to test the relationship between the concentration and distribution of women and minorities in distressed industries--those which are experiencing deindustrialization or a decline in employment-and structural changes in the American economy and to make projections about the U.S. labor market as a whole.

The primary task was to analyze empirical data collected from a sample of the 1980 and 1970 Census Fublic Use tapes. Information was selected from the characteristics of the four major groups comprising the labor force--white males, white females, nonwhite males; and nonwhite females.

The objective of the labor market analysis is to discern whether structural changes in the us economy have affected the observed employment patterns of women and minorities ie. increasing or decreasing shares in specific sectors over the past ten to fifteen years. The focus of the analysis was to look at the relationship between demographic trends in the composition of the work force and the process of industrial change. This will be accomplished by identifying changes in the labor market participation rates within sectors and also
looking at the distribution of women and minority workers across sectors.

The census sample allows for an investigation of several dimensions of disaggregated information on population characteristics related to the labor market ien industrial concentrations: geographic distributions: and age/sex differentials that are of interest. The following are of interest for this research:
-Within industries identified as deindustrializing: are there any particular sex and or racial groups which are disproportionately experiencing greater changes in employment share for restructuring and deindustrializing industries relative to growth industries?
--Are the changes in the composition and distribution of the work force in the us labor marlet attributable to industrial restructuring of selected industries? What is the ratio of nonwhite to white changes in employment?
--Do declines in employment or changes in the employment patterns tend to be more acute in industries undergoing structural changes than other industries?

The principal measurement applied to the data will take the form of a matrix; a table of industries by sex and race for 1980 and 1970. Statistical tests, difference between sample means and chi square tests were performed to compare the relative proportions of specific sectors over the ten year
period.
The industries were classified into two groups for analysis. The reason for detailing information on specific industries is that sectorial changes are not always reflected in aggregate measures of the overall economy.

Group I consists of the "Growth" industries. These industries experienced employment growth in the 1970's even after accounting for the business cycle and international trade. Group II consists of the "Nongrowing" industries. These industries are typically those which are experiencing a decline in employment share as the result of some form of deindustrialization or restructuring. See Tables 3 and 4 for the "Growth" and "Nongrowing" industry groupings. Thirtyeight of the 82 or 46 percent of the BEA industries are Group I - Growth Industries, 44 or 54 percent are Group II Nongrowing Industries.

Data Collection:
The U.S. Census is the primary data source for the research. Data was obtained through a .01\% sampling of the Census Public Use Sample ' $A$ ' tapes. From that sample a 20 percent subset was selected for projecting population employment estimates for this analysis. The 1980 and 1970 samplings resulted in 20789 and 15993 observations respectively. All information was selected from the civilian labor force which includes all persons 16 years or older who were employed at work, employed not at work, or unemployed and seeking work. The following variables were selected for the population from the census tapes:
Census Category DIVISION:
New England Middle Atlantic
East North Central
West North Central
South Atlantic
East South Central
West South Central
Mountain
Pacific
SEX:

    classification (SIC))
```

OCCUF'ATION:

```
(individual occupation (3 Digit codes)
    categories)
(3 Digit codes) categories)
```

LABOF STATUS:
At work: 1
Not at work; with job
2 Unemplayed
$\pm$

The above variables were selected from the household and person records for 1980 and from the neighborhood record for 1970.

Once the raw census information was stored on tapes the data was reorganized using SAS statistical programs before being grouped by sex, race and industry codes for analysis.

The 3 digit census industrial classifications (CIC) codes were recoded to the Eureau of Economic Analysis (EEA) Industry Codes for the purpose of standardization and for making comparisons. See Appendices $A$ and $E$ for EEA SIC and CIC equivalents.

The variable "race" was also redefined from the census 9 sub-groupings to white and non-white. The variatle Spanish was used to identify any person of Spanish or Hispanic origin who might have listed themselves as white in the census questionnaire. Fersons fitting this description were defined as nonwhite.

The division and occupation variables were not used in this analysis. Therefore, these variables were not recoded and remain as they appear on the census sample tape.

The census data was then arranged into 4 tables :

Sex * industry
Face * industry
Sex * industry controlling for race
Face * industry controlling for sex
The purpose of this tast was to create a matrix which illustrates the population proportions by industry, sex and race. See tables 5 and 6 for the 1970 and 1980 results respectively.

## 므트 Analy巨i巨ㅗ

Industries were divided into the growth categories according to trends in employment and controlling for business cycles and the foreign exchange rate. Of Group I - Growth Industries 29 out of 39 industries were in the manufacturing and mining sectors. While 45 or the 53 industries or 85 percent of the Group II - Nongrowing Industries were in the manufacturing and mining sectors.

After assigning the BEA coded industries to the growth categories. the data was tested for the following hypotheses.
(1) Does knowing the composition of the work force of an industry in 1980 help to explain what type of industrial change occurred in the $1970^{\circ} 5$ ?
(2) Does industrial restructuring effect a pattern of changing employment share between growth and nongrowing industries? Does this change the composition of the work force?

For the first hypothesis, a chi square test for independence was performed for 1980 and 1970 on the aggregated industry categories.
1980
White Male
Nonwhite Male
White Female
Nonwhite Female

Growth
$6064(58.57 \%)$
$795(50.16 \%)$
$3788(50.91 \%)$
$514(56.48 \%)$
Nongrowing
4290 (41.43 \%) $790(49.84 \%)$
$3653(49.09 \%)$
895 (6.3.52 \%)

$$
\begin{aligned}
& 1980 \times 2=159.52 \\
& 1970 \times= \\
& 2 \\
& 3 \text { d.f. } \\
& \text { critical at . } 05=7.81473 \\
& .01=11.3449
\end{aligned}
$$

The chi square tests confirmed that in 1980 and 1970 there were differences between the demographic composition of Growth and Nongrowing industries by sex and race.

The other hypothesis was tested using a difference between sample means test to see if the demographic proportions or shares between the industry categories changed from 1970 - 80. The results were not significant. It appears that in the aggregate, there were no significant changes in the demographic composition of the two categories over the ten year interval.

However, looking at industries in which women and minorities represent a large percent of the industry work force did present evidence that women are increasingly comprising a larger share of employment in nongrowing industries as seen in Table $9-11$. Table 7 is presented to mate comparisons with the employment pattern of white males in the work force.

Tables 8 and 10 show that the same is true for minority workers, who appear in very different industries in 1980 than 1970. The movement, however, tends to shift mostly within Group II - Nongrowing Industries.

## INDUSTRIES WITH HIGHEST FROFORTION WHITE MALE

## Summary of Findings:

(1) White male workers are presented as a standard for the purpose of comparison, in 19704 of the 10 industries which employed the highest proportions--"top ten" industries-of white males were nongrowing. Ey in 1980, 3 of the 10 were nongrowing industries.
(2) For nonwhites, 7 of the 10 industries were nongrowing both in 1970 and 1980. The industries making up the "top ten" list were fairly unstable. Half or 5 of the 1970 industries were replaced in the top rankings by different industries in 1980.
(3) For females, 5 of the top 10 industries with large proportions of women in 1970 were nongrowing. Ey 1980,7 of the top 10 industries were nongrowing. The industries making up the 'top ten" list, Table 9, were fairly stable. Six of the industries retained the same ranking from 1970 to 1980. Only three of the 1970 industries were replace by differnt industries in 1980, of which all were of Group II - Nongrowing Industries.
(4) For nonwhite females, 9 of the 10 industries with the highest proportions of nonwhite females in 1970 were nongrowing industries. These industries were also different from the 'top ten" industries for nonwhites in general. By 1980, 7 of the 10 industries with high proportions of nonwhite female workers were in Group II - Nongrowing Industries.
(5) For white females: 4 of the 10 industries were nongrowing both in 1970 and 1980. Half or 5 of the 1970 industries were replaced in the top rankings by different industries in 1980.

The significance tests show no changes in the aggregate between the share of women and minorities by industry category from 1970 to 1980 . However, there may by reason to infer that there is a relationship between industries in which women comprise a large proportion of the work force and industries which are categorized as Group II - Nongrowing Industries as Table 9 and 10 show. The concluding chapter will discuss the implication of these findings.

## CHAPTER THEEE

REVIEW OF RESEARCH

The current economic crisis caused by structural changes in the U.S. economy has had measurable affects on the concentration and distribution of workers within and across specific industries in the U.S. economy. Women and minority worters tend to be employed in tigher concentrations in distressed--restructuring and deindustrializing--industries and therefore are directly affected by the economic condition of these industries.

Changes in the employment patterns of women and minorities as described in the industry by sex and race matrix of the previous chapter are consistant with the hypothesis that the economic hardships associated with industrial restructuring have been experienced disproportionately by workers of these groups.

Two distinct observations relating the impact of structural structural changes and the employment of women and minority workers can be drawn from the research of this thesis. They are as follows:
(1) Nonwhite workers are employed in higher concentrations relative to their work force rates in Group II Nongrowing Industries than white workers. In 1980, nonwhite
workers represented 17.50 percent of the workforce in nongrowing industries while only comprising 14.40 percent of the total work: force. Minority workers as a group are more likely to experience economic dislocation resulting from industrial restructuring and structural changes than their white counterparts.
(2) Women, particularly nonwhite females, are not employed in growth industries in proportion to their work force rates. In 1980, female workers made up 42.87 percent of the total work force while only comprising 8.54 percent of the work force of growth industries. Even though more women are increasingly entering the work force, they are not necessarily participating in the new of jobs created in growth industries. And finally, industries where women are a large proportion of the work force tend to be nongrowing rather than growing industries.

This research has resulted in some very interesting and useful findings regarding the economic and labor market status of women and minority workers. The observations presented above will be further developed. However, for the purpose of mating comparisons: summary information on the composition of the workforce by sex and race is supplied as follows:

| Sample observations for |  |  |
| :--- | :--- | :--- |
| Workforce Fates (\%) | 1970 |  |
| White | 1989 | 190 |
| Nonwhite | 85.60 | 88.46 |
| Male | 14.40 | 11.54 |
| Female | 57.43 | 61.35 |
|  | 42.57 | 38.65 |

| Sample Observations for Workforce Rates (\%) | Growth | Nongrowing |
| :---: | :---: | :---: |
| White Male | 54.35 | 44.56 |
| Nonwhite Male | 7.12 | 8.21 |
| White Female | 35.94 | 37.94 |
| Nonwhite Female | 4.60 | 9.30 |

Declines in employment of particular manufacturing industries have had adverse affects on the employment of nonwhite workers. In 1970, nonwhite males comprised 14.29 percent of the rubber industry. By 1980, that number had fallen a dramatic eleven percentage points to $3.40 \%$. Contrast this with white males, who in 1970 made up 62.50 percent of the rubber industry and 68.84 percent in 1980. Clearly, nonwhite males faced dislocation within this industry while white males sustained slow growth. This type of decline, though not as severe, was similarly experienced by the motor vehicles industries where in 197014.71 percent of the workforce was nonwhite contrasted to $12.33 \%$ percent in 1980.

Although these two examples of declining shares of manufacturing employment industries are not truly representative of the entire sector, they do illustrate the point that
employment declines in the manufacturing sector as severe as those in the rubber industry can have very adverse effects on the composition of the industry work force as well as labor market conditions of workers.

Lite minorities: white women have also experienced the impacts of industrial restructuring. Women tend to be employed in large proportions in nongrowing industries. This is especially true for nonwhite women. This group has teen clearly effected by structural changes occurring in the economy.

In 1970; nonwhite women were 4.9 percent of the total work forces yet their work force rate was 6.67 percent in nongrowing industries. Ey 1980, these numbers had changed to 6. 78 percent for the total work force and 9.30 percent work force in nongrowing industries. Nonwhite wamen as a percentage of the total nonwhite work force in growth industries remained fairly constant ranging from 37.32 percent in 1970 and 39.27 percent in 1980.

These findings all support the hypothesis that the impacts of industrial restructuring bear very heavily on women and minority workers. This data show that nonwhite workers are not participating in the expanded job opportunities created by growth industries, but are continuing to be concentrated in declining and distressed industries. Further research of this nature must be conducted to ensure that the problems and issues which concern these groups of workers are addressed in the midst of this economic transformation.

## EiEsearch Eecommendations:

This particular research effort was purposefully defined to have a limited scope. Further work on this subject should be conducted to both substantiate and expand upon these findings but also to continue to aid in the political and economic battle in which the target group of this research--women and minorities--find themselves.

There are several possible "next steps" to take in pursuing research on the relationship between industrial restructuring and the employment patterns and concentrations by industry of particular workers. Firstly, when beginning this process, the census characteristics age, racial group, region/division, occupation, and labor status were considered important to the research. None of these characteristics, however, except racial group were used in this investigation.
"Race" was used only in a aggregated form of white and nonwhite. There is, however, likely to be more variation amongst workers when more detailed information about race is surveyed. For example, reports from the Bureau of Labor Statistics and the U.S. Census show that while low wage industries employ a high percentage of women workers in general: Hispanic women were found in higher percentages than all women in the leather products, household and furniture manufacturing, and banking industries. Similarly, white women make up a very large pro- portion of the females employed in the electronic components and electrical equipment industries. [Gorham, p.65] These variations by industry type and
occupation by racial breakdown apply to men as well. This type of data would strenghten the argument of who-which group or class of workers--imparticularly or more severly bears the burden of industrial restructuring in specific industries. Another factor that would be of use is geographical/ regional information on employment. This characteristic would certainly detect the effect of plant closures and site relocations as in the shift of industries from the Snowbelt to the Sunbelt regions. This regional dimension would also reflect the effects of worker migration like the rural to urban movement on employment share by industry.

Another principal correlation that needs to be researched in detail is the relationship between wages and occupations as they relate to industrial restructuring and specific groups of workers. Eoth person and family household income figures would be of interest as today most households have more than one wage earner. Dccupational status seems to vary greatly between sectors. The effect of industrial restructuring on this characteristic would provide significant information about the economic condition of worters within sectors.

As this research effort has shown, there is a relationshp between economic structural changes and the changing composition composition and distribution of workers in the economy. Further research possibly using the above mentioned demographic statistics might extend this investigation further to look for causality.

## CHAPTEE FQUE

CONCLUSION

The purpose of this investigation was to collect data on the employment patterns of American industries--with particular interest in restructuring and deindustrializing industries--to relate observable changes in the concentration and distributions of particular groups of workers--women and minorities--to the current structural changes occurring in the U.S. economy.

The findings presented in the previous chapters illustrate a worsening labor force status for women and minorities in the U.S. labor market. The current structural economic transformation is believed by many to effect the concentration and distribution of employment shares by industry of these groups. The research presented in this thesis documents and supports this hypothesis. The findings also suggest that the effects of industrial restructuring are particularly noticeable in the case of nonwhite female workers.

This research is important because it quantitatively describes and illustrates the economic inequalities which exist in the U.S. labor market. The impact of the current economic crisis and of structural changes occurring in the economy when measured by employment have been clearly
distributed unequally amongst American workers.
The fact that women and minorities are replacing employment shares in traditionally above-average wage manufacturing jobs with rapidly expanding low wage occupationally polarized service jobs potentially creates a problem for the future of the labor market and society as well. If women and minorities expect any positive form of social restructuring to result from this process of industrial restructuring they must engage and become active participants in the industrial policy debate.

Improvements in the economic: political, and social status of [women and minorities] are joint effects. Failure to realize the interdependences makes success or improvement in any of the areas unlikely. [Marcus Alexis: P. 351$]$

The tast: facing the leadership of these groups is to organize their resources to generate and sustain interest in the issue of industrial policy.

Industrial policy promises to be a major issue in the coming years. As a vehicle for economic change, industrial policy is aimed at industries and not workers per se. However, the role of governmental involvement in strategic economic planning suggests that issues of market inefficiencies will be addressed, much to the benefit of groups less represented in the labor force. [McGahey, p. 91] To this extent, the overall economic condition of women and minority workers is likely to be improved by this targeted policy.

In concluding: it is important to reiterate that the economic environment which is now taking shape offers both opportunities and challenges for women and minorities. The service sector is growing. A number of new employment opportunities are being created to replace the lossess of traditional manufacturing employment. The dilemma, however: is that while these new opportunities are in growth industries. oftentimes the wage levels and job benefits do not compare favorably with that of manufacturing employment.

The future socioeconomic status and labor market conditions of women and minority workers will: to an extent, be a product of the dynamic structural changes currently taking place in the U.S. economy. The impact of these changes obviously are not experienced only by the workers: but also effect most immediately the households and communities of the workers as well. For these reasons, the effect of labor market condi-tions--restructuring and deindustrializing industries--on the wort: force concentration and household characteristics of women and minorities is an issue of increasing concern which should continue to be investigated.

The message of all this is that women and minorities are still a very long way from achieving anything resembling economic parity with white males. The current economic transformation has affected the economic status and labor market conditions of women and minorities across industrial sectors. Industrial restructuring: while also a process of social restructuring does not promise to reduce the socioeconomic
differentials between the majority and minority groups of American society. This process will continue until governmental intervention is taken on behalf of women and minority workers.
