20

1 **Summary**

2 The obesity epidemic is a significant global health issue. Improved understanding of the
3 mechanisms which regulate appetite and body weight will provide the rationale for the
4 design of anti-obesity therapies. Thyroid hormones play a key role in metabolic homeostasis
5 through their interaction with thyroid hormone receptors (TR), which function as ligand
6 inducible transcription factors. The TR beta isoform (TR β) is expressed in the ventromedial
7 hypothalamus (VMH), a brain area important for control of energy homeostasis. Here we
8 report that selective knock down of TR β in the VMH of adult mice results in severe obesity
9 due to hyperphagia and reduced energy expenditure. The observed increase in body weight
10 is of a similar magnitude to murine models of the most extreme forms of monogenic obesity.
11 These data identify TR β in the VMH as a major physiological regulator of food intake and
12 energy homeostasis.

13

14 **Introduction**

15 Energy homeostasis is regulated by neurotransmitters and by humoral factors including
16 thyroid hormones, which act within the hypothalamus and systemically to regulate food
17 intake (Coppola et al.,2007; Coll et al.,2007) and energy expenditure (Kim, 2008). The
18 effects of the active form of thyroid hormone, 3,5,3'-L-triiodothyronine (T3), are mediated by
19 two thyroid hormone receptors (TR α and TR β), encoded by *Thra* and *Thrb* respectively
20 (Brent, 2012).

21

22 Metabolic phenotypes have been described in mice and humans with TR mutations. Mice
23 with heterozygous dominant negative mutations of TR α display a variety of metabolic
24 phenotypes ranging from hypermetabolism, hyperphagia and resistance to diet induced
25 obesity (Sjogren et al.,2007) to increased visceral adiposity, hypophagia and impaired cold
26 induced adaptive thermogenesis (Liu et al., 2003). The variation in described phenotypes is
27 likely to be due to the differing actions of individual mutant receptors on wild type TR function
28 (Ortiga-Carvalho et al.,2014). Humans with heterozygous dominant negative mutations of

1 TR α (resistance to thyroid hormone α , RTH α) may be overweight or obese with reduced
2 energy expenditure (Bochukova et al., 2012; Moran et al., 2013; Moran et al., 2014).
3 Humans with heterozygous dominant negative mutations of TR β have RTH β resulting in
4 high levels of circulating thyroid hormones and thyroid stimulating hormone (TSH) due to
5 impaired negative feedback of the hypothalamic-pituitary-thyroid axis (Ortiga-Carvalho et
6 al.,2014). Humans with RTH β may be overweight and hyperphagic (Mitchell et al.,2010)
7 despite features of hyperthyroidism such as tachycardia and raised energy expenditure due
8 to T3 actions in TR α responsive tissues. These extensive studies demonstrate that thyroid
9 hormone is an essential regulator of food intake and energy expenditure. Despite this,
10 clinical and global gene targeting studies cannot differentiate between the developmental
11 and adult, or systemic and central, effects of thyroid hormones.

12

13 The ventromedial hypothalamus (VMH) is a critical region of the brain involved in energy
14 homeostasis. TR β is the predominant TR isoform expressed in the VMH (Cook et al.,1992;
15 Barrett et al.,2007) and previous studies suggest that thyroid hormones acting in the VMH
16 regulate both food intake (Kong et al.,2004) and energy expenditure (Lopez et al.,2010).
17 Thus, we hypothesize that, in the VMH, TR β physiologically regulates food intake and body
18 weight. To investigate this hypothesis directly we used stereotaxic Cre-lox gene targeting to
19 generate a VMH-specific model of TR β knock down in adult mice.

20

21 **Results**

22 **Tissue specific knock down of TR β in the VMH in adult mice**

23 We knocked down TR β in the VMH of adult male mice using Cre-mediated excision of a
24 floxed critical exon in the *Thrb* gene. This approach enabled temporally and spatially
25 controlled reduction of TR β expression specifically in the VMH of adult mice. This model
26 eliminates the developmental consequences and abnormal systemic thyroid hormone levels
27 that occur in global TR β mutant mice (Ortiga-Carvalho et al.,2014) or in hypothyroid and
28 thyrotoxic animals (Ishii et al.,2003; Lopez et al.,2010).

1 The *Thrb*^{flox} allele contains loxP sites flanking exon 5 of *Thrb* (Winter et al.,2009) (Figure
2 S1A). *Cre-recombinase* mediated excision of this critical exon results in inactivation of *Thrb*
3 (Winter et al.,2009). *Cre recombinase* was introduced into the VMH of adult male *Thrb*^{flox/flox}
4 mice by stereotaxic injection of recombinant adeno-associated virus (rAAV) expressing a
5 Cre-GFP fusion protein to generate mice with reduced TR β expression in the VMH (VMH-
6 TR β ⁻) mice. *Thrb*^{flox/flox} mice injected with rAAV encoding GFP into the VMH (VMH-GFP) were
7 used as controls. Cre-mediated excision of the *Thrb*^{flox} allele was confirmed by PCR of DNA
8 from whole hypothalami of VMH-TR β ⁻ mice (Figure S1B). The *Thrb*^{flox} allele was not excised
9 in either the cerebellum or brainstem, indicating rAAV did not enter the ventricular system
10 following stereotaxic injection (Figure S1B). Fluorescence microscopy and *in situ*
11 hybridisation (*ISH*) both confirmed transgene expression localized to the VMH in both groups
12 of mice (Figure S2A,B). *ISH* using a probe specific for the floxed exon of *Thrb* demonstrated
13 reduced expression within the VMH of VMH-TR β ⁻ mice compared with controls (Figure
14 S2C,D).

15

16 **Selective knock down of TR β in the VMH in adult mice results in hyperphagia and** 17 **obesity**

18 VMH-TR β ⁻ mice consumed more food and gained more weight than controls (Figure 1A,B).
19 Weight gain in VMH-TR β ⁻ mice was three times greater than that of control mice by the end
20 of the study (Figure 1C,D).

21

22 Whole hypothalami for RNA-Seq analysis were collected from mice before significant
23 changes in body weight had occurred. This was so that changes in expression are likely to
24 be due to changes in thyroid hormone signalling rather than secondary effects of the
25 increase in body weight and food intake. Differential expression analysis was performed
26 (Table S1). Pathway analysis of differentially expressed genes revealed an over-
27 representation of genes involved in dopamine, growth hormone and leptin signalling
28 pathways, as well as genes that are involved in neuronal activity regulation including long-

1 term potentiation (LTP) and long-term depression (LTD), these results were qualitatively the
2 same when the FDR for analysis was set between 0.001 and 0.1 (Table S2). Among the
3 genes differentially expressed *Pomc* expression was decreased (log Fc -1.38, p= 9.33x10⁻⁷)
4 (Figure 1E) whilst *Npy* expression was increased (log Fc 0.7 p = 9.42 x 10⁻⁶) (figure 1F)
5 whilst that of *Thrb* was not altered at the level of the whole hypothalamus (Table S1).
6 Expression of *steroidogenic factor 1 (Sf-1)*, and *uncoupling protein-2 (Ucp-2)* both of which
7 are implicated in hypothalamic control of energy homeostasis (Majdic et al., 2002; Coppola
8 et al., 2007) were unchanged. The differentially expressed genes were compared to those
9 previously reported to be T3 responsive or directly regulated by T3 in cerebrocortical cells
10 (Table S1 and S2 and Figure S3) (Gil-Ibanez et al., 2017). Of the genes directly regulated by
11 T3 in cerebrocortical cells we identified 89 (approx. 15%) were also significantly changed in
12 our samples among which was *hairless (Hr)*. For genes regulated indirectly by T3 we
13 identified one-hundred and thirty three that were also changed (approx. 9%).

14
15 Total, visceral, subcutaneous, and epididymal fat mass were all increased in VMH-TRβ⁻ mice
16 compared to controls (Figure 2A-E). In keeping with the increased adiposity, VMH-TRβ⁻ mice
17 had a higher plasma leptin concentration than controls (Figure 2F).

18

19 **VMH-TRβ⁻ mice are systemically euthyroid**

20 Alterations in circulating thyroid hormones affect food intake and body weight (Pijl et
21 al.,2001). Measurement of plasma TSH, thyroxine (T₄) and T₃ confirmed that both VMH-
22 TRβ⁻ and control mice were euthyroid (Figure S4A-C).

23

24 **VMH-TRβ⁻ mice are insulin resistant but do not show changes in the expression of 25 genes involved in hypothalamic glucose sensing**

26 Obese VMH-TRβ⁻ mice had high levels of fasting insulin (Figure S4D) as expected. However
27 when glucose tolerance and insulin tolerance were tested before the development of obesity
28 in the VMH-TRβ⁻ mice there were no differences between the VMH-TRβ⁻ and VMH-GFP

1 mice (Figure S4E,F). RNA-Seq analysis did not identify changes in expression of
2 hypothalamic glucose sensing genes.

3

4 **Obesity in VMH-TR β ⁻ mice is not due to TR β knock down in other brain areas**

5 To confirm that the observed weight gain and hyperphagia in VMH-TR β ⁻ mice resulted from
6 reduced TR β expression in the VMH and not spread through the ventricular system into
7 other brain regions, recombinant rAAV-Cre was injected into both lateral ventricles of
8 *Thrb*^{fllox/fllox} mice; a control group of mice were injected with rAAV-GFP. There was no
9 difference in cumulative food intake or body weight gain between these two groups (Figure
10 S4G,H).

11

12 **VMH-TR β ⁻ mice fail to mount an orexigenic response to administered T3**

13 In order to validate loss of T3 signalling following TR β inactivation in the VMH, we
14 administered T3 to VMH-TR β ⁻ and VMH-GFP mice by subcutaneous injection. Over the 24
15 hour study period, T3 significantly increased food intake in VMH-GFP mice but VMH-TR β ⁻
16 mice failed to mount an orexigenic response to the administered T3 (Figure S4I).

17

18 **VMH-TR β ⁻ mice do not become obese when pair-fed to the food intake of lean controls**

19 To investigate whether the hyperphagia contributed to, or was a consequence of, the
20 development of the obese phenotype, VMH-TR β ⁻ mice were pair-fed to the food intake of a
21 weight-matched VMH-GFP littermate for five weeks. During pair-feeding, there was no
22 difference in cumulative body weight change or food intake (Figure 3A,B) or locomotor
23 activity between the two groups.

24

25 After five weeks of pair-feeding, *ad libitum* access to food was restored for four weeks.
26 Following restoration of free feeding, VMH-TR β ⁻ mice gained significantly more weight and
27 consumed significantly more food than controls (Figure 3A,C).

28

1 **VMH-TR β ⁻ mice have reduced energy expenditure and reduced locomotor activity**

2 The contribution of changes in energy expenditure to the obese phenotype was investigated.
3 Oxygen consumption (VO₂), carbon dioxide production (VCO₂) and locomotor activity were
4 all decreased during the dark phase in *ad libitum* fed VMH-TR β ⁻ mice both before and after
5 the onset of obesity (Figure 4A-C). By contrast, there was no difference in VO₂, VCO₂ or
6 locomotor activity during the light phase (Figure 4A-C). The decrease in nocturnal
7 locomotion in VMH-TR β ⁻ mice was confirmed by behavioural analysis (Table S3). There was
8 no difference in respiratory exchange ratio (RER) (Figure 4D) and no difference in brown
9 adipose tissue (BAT) *uncoupling protein-1* (*Ucp-1*) expression (Figure 4E) between VMH-
10 TR β ⁻ and control mice. In addition, VMH-TR β ⁻ mice have a normal body temperature (Figure
11 S4J).

12

13 **Discussion**

14 These studies identify hypothalamic TR β as an important physiological regulator of appetite
15 and body weight. Reduced TR β expression in the VMH resulted in marked weight gain,
16 comparable to severe forms of monogenic obesity (Tecott et al.,1995; Yaswen et al.,1999).
17 The weight gain was a consequence of increased total body fat, and in particular a marked
18 increase in subcutaneous and visceral white adipose tissue, the latter being an important
19 risk factor for cardiovascular disease and diabetes (Montague and O'Rahilly, 2000).

20

21 VMH-TR β ⁻ mice ate more than control animals and pair-feeding studies indicated that
22 hyperphagia contributed directly to the obesity. Thus, VMH-TR β ⁻ mice remained lean when
23 food intake was restricted but rapidly became obese when *ad libitum* feeding was restored.

24

25 Selective TR β knock down specifically in the VMH was confirmed by *ISH* and fluorescence
26 microscopy. Although expression of *Thrb* was not reduced in the RNA-Seq analysis, these
27 samples are derived from whole hypothalami and therefore the decrease in the level in the
28 VMH is likely masked by the expression of *Thrb* throughout the rest of the sample. Indeed

1 the loss of TR β function in the VMH was demonstrated by the failure of the expected
2 orexigenic response to administered T3 in VMH-TR β ⁻ mice and further supported by the
3 appropriate changes in genes directly regulated by T3. The possibility of the phenotype
4 arising through virus spread to other CNS areas was excluded by rAAV-Cre injection into the
5 lateral ventricles, which did not result in hyperphagia or obesity.

6

7 Previous work in rats has reported the acute orexigenic effect of exogenously administered
8 T3 (Kong et al., 2004). Here we show the endogenous effect of thyroid hormone action
9 following selective TR β knock down. We suggest that our current work describes a local
10 circuit within the VMH that physiologically regulates food intake as distinct from the feeding
11 response to administered pharmacological doses of T3 analogous to the contrasting effects
12 of NPY and PYY.

13

14 To investigate the underlying cause of hyperphagia in VMH-TR β ⁻ mice, hypothalamic gene
15 expression patterns were determined by RNA-Seq. The expression of *Pomc* and *Fto* were
16 down-regulated in the hypothalamus, whilst *Npy* was upregulated. POMC and FTO are
17 thought to inhibit food intake whilst NPY stimulates food intake; therefore these changes in
18 expression may explain in part the phenotype observed.

19

20 Energy expenditure in VMH-TR β ⁻ mice was reduced both before and after the onset of
21 obesity. There was no difference in BAT *uncoupling protein-1* (*Ucp-1*) expression between
22 VMH-TR β ⁻ and control mice suggesting that adaptive thermogenesis was unaffected. It is
23 likely that changes in energy expenditure in VMH-TR β ⁻ mice resulted from decreased
24 locomotor activity. The reduced locomotor activity is not a consequence of the obesity since
25 it occurred before differences in body weight. In addition, during pair-feeding studies the
26 reduction in locomotor activity was lost, possibly due to food seeking behaviour. This is likely
27 to explain why body weight gain did not differ between the two groups before the restoration
28 of *ad libitum* feeding. The energy expenditure and pair-feeding data indicate that both

1 increased food intake and reduced locomotor activity contribute to obesity in VMH-TR β -
2 mice.

3

4 In contrast to VMH-TR β - mice, global heterozygous TR β knockout mice do not have an
5 obese phenotype (Ortiga-Carvalho et al.,2014). This may be explained by the peripheral
6 hyperthyroidism of these mice. In addition, the appetite circuits within the hypothalamus are
7 subject to developmental plasticity and compensatory redundancy (Bouret et al.,2004;
8 Horvath, 2005). For example, neither global deletion of *Agrp* and/or *Npy* nor ablation of
9 arcuate AgRP/NPY neurons in neonatal mice results in a metabolic phenotype (Erickson et
10 al.,1996; Qian et al.,2002; Luquet et al.,2005), whereas ablation of these neurons in adult
11 mice produces profound hypophagia and starvation (Luquet et al.,2005; Gardiner et
12 al.,2005; Bewick et al.,2005). Similar developmental compensation may occur in global TR β
13 knockout mice.

14

15 Studies using adenovirus mediated expression of a dominant negative TR (DN-TR) in the rat
16 VMH have been reported (Lopez et al.,2010). Although, VMH DN-TR expression did not
17 affect food intake or body weight in euthyroid animals, it prevented weight loss in thyrotoxic
18 rats and resulted in reduced hypothalamic *AMP-activated protein kinase (Ampk)* expression
19 (Lopez et al.,2010). *Ampk* expression was unchanged in our model. DN-TR interferes with
20 the actions of both TR α and TR β and exerts a marked repressive effect on gene
21 transcription (Ortiga-Carvalho et al.,2014; Ferrara et al.,2012). By contrast, VMH-TR β - mice
22 have only reduced TR β activity rather than the pathological repression of TR target genes
23 that is present in animals expressing a dominant negative receptor. This fundamental
24 difference is likely to explain the contrasting phenotypes observed in these two models.

25

26 In summary, we have shown that hypothalamic TR β is an important physiological regulator
27 of energy homeostasis because TR β knock down in the VMH results in a phenotype of
28 hyperphagia and severe obesity that is comparable to some of the most extreme forms of

1 monogenic obesity (Tecott et al.,1995; Yaswen et al.,1999). Our findings provide insights
2 into the central regulation of energy homeostasis by TR β that could be a target for anti-
3 obesity therapies.

1 **Experimental Procedures**

2 **Animals**

3 *Thrb^{flox/flox}* mice (Winter et al.,2009) were genotyped by PCR using specific oligonucleotide
4 primers (Figure S1). Mice were housed in single cages and maintained under a
5 controlled environment (temperature 21–23 °C, 12-h light–dark cycle, lights on at
6 07:00) with *ad libitum* access to chow and water (RM1; SDS Diets), except where
7 stated. Male mice which were eight weeks old at the start of procedures were used
8 in all experiments. All animal studies were approved under the Animals (Scientific
9 Procedures) Act (1986) (Project License number 70_7229) and approved by the
10 Animal Welfare and Ethical Review Body, Imperial College London, which is signed
11 up to the ARRIVE guidelines.

12

13 **Recombinant AAV preparation**

14 Recombinant AAV was produced (Grimm et al.,1998) and isolated (Zolotukhin et al.,1999)
15 as previously described.

16

17 **Confirmation of rAAV transgene expression, *Thrb* excision and reduced TR β 18 expression in the VMH**

19 Excision of the *Thrb^{flox}* allele within the hypothalamus was confirmed by PCR (Figure S1).
20 *ISH* using a probe specific to the excised portion of TR β was performed to confirm reduced
21 TR β expression within the VMH (Smith et al., 2008).

22

23 **Measurement of energy expenditure**

24 Metabolic parameters were measured by indirect calorimetry using an open-circuit Oxymax
25 system of the Comprehensive Lab Animal Monitoring System (Columbus, OH, USA)
26 (Gardiner et al., 2010).

27

1 **RNA-Seq analysis**

2 RNA-Seq analysis was performed using hypothalamic RNA from VMH-GFP (n=3) and VMH-
3 TRβ⁻ (n=4) mice using Next Generation Sequencing (NGS) technologies (Imperial BRC
4 Genomics Laboratory, Imperial College London). For further details see Supplemental
5 Experimental Procedures.

6

7 **Statistical Analyses**

8 Cumulative food intake and body weight data were analyzed using generalized estimating
9 equations with exchangeable correlation matrix and robust standard errors. Differences
10 between two groups at individual time points were analyzed by unpaired t-tests, for multiple
11 comparisons a Bonferroni correction was applied. Values from the behavioural study were
12 analyzed using a one way ANOVA followed by Kruskal-Wallis test. Data from the energy
13 expenditure test were analyzed using a one way ANOVA followed by a Newman-Kuels test.
14 Plasma thyroid hormones were compared using Mann-Whitney U test. Differences between
15 groups were considered statistically significant at the 95% confidence level (P<0.05).

16

1 **Author Contributions**

2 SH, MP, WSD, SAR, YM, CH, WF and JVG conducted the majority of the experiments. SH,
3 WSD, SRB, JHDB, GRW and JVG wrote the manuscript. SAR and AG maintained the mice.
4 AG and JHDB prepared the TR β probe. JB and JA performed the MRI study. GSHY, BYHL
5 and JPW performed the RNA-Seq experiments and analysis, JS generated the *Thrb*^{flox/flox}
6 mice. WSD, SRB, JHDB, GRW and JVG conceived of and supervised the project. All
7 authors discussed the results and commented on the manuscript.

8

9 **Accession numbers**

10 The accession number for the RNA-Seq data reported in this paper is GEO: GSE98690

11

20

1 **Summary**

2 The obesity epidemic is a significant global health issue. Improved understanding of the
3 mechanisms which regulate appetite and body weight will provide the rationale for the
4 design of anti-obesity therapies. Thyroid hormones play a key role in metabolic homeostasis
5 through their interaction with thyroid hormone receptors (TR), which function as ligand
6 inducible transcription factors. The TR beta isoform (TR β) is expressed in the ventromedial
7 hypothalamus (VMH), a brain area important for control of energy homeostasis. Here we
8 report that selective knock down of TR β in the VMH of adult mice results in severe obesity
9 due to hyperphagia and reduced energy expenditure. The observed increase in body weight
10 is of a similar magnitude to murine models of the most extreme forms of monogenic obesity.
11 These data identify TR β in the VMH as a major physiological regulator of food intake and
12 energy homeostasis.

13

14 **Introduction**

15 Energy homeostasis is regulated by neurotransmitters and by humoral factors including
16 thyroid hormones, which act within the hypothalamus and systemically to regulate food
17 intake (Coppola et al.,2007; Coll et al.,2007) and energy expenditure (Kim, 2008). The
18 effects of the active form of thyroid hormone, 3,5,3'-L-triiodothyronine (T3), are mediated by
19 two thyroid hormone receptors (TR α and TR β), encoded by *Thra* and *Thrb* respectively
20 (Brent, 2012).

21

22 Metabolic phenotypes have been described in mice and humans with TR mutations. Mice
23 with heterozygous dominant negative mutations of TR α display a variety of metabolic
24 phenotypes ranging from hypermetabolism, hyperphagia and resistance to diet induced
25 obesity (Sjogren et al.,2007) to increased visceral adiposity, hypophagia and impaired cold
26 induced adaptive thermogenesis (Liu et al., 2003). The variation in described phenotypes is
27 likely to be due to the differing actions of individual mutant receptors on wild type TR function
28 (Ortiga-Carvalho et al.,2014). Humans with heterozygous dominant negative mutations of

1 TR α (resistance to thyroid hormone α , RTH α) may be overweight or obese with reduced
2 energy expenditure (Bochukova et al., 2012; Moran et al., 2013; Moran et al., 2014).
3 Humans with heterozygous dominant negative mutations of TR β have RTH β resulting in
4 high levels of circulating thyroid hormones and thyroid stimulating hormone (TSH) due to
5 impaired negative feedback of the hypothalamic-pituitary-thyroid axis (Ortiga-Carvalho et
6 al.,2014). Humans with RTH β may be overweight and hyperphagic (Mitchell et al.,2010)
7 despite features of hyperthyroidism such as tachycardia and raised energy expenditure due
8 to T3 actions in TR α responsive tissues. These extensive studies demonstrate that thyroid
9 hormone is an essential regulator of food intake and energy expenditure. Despite this,
10 clinical and global gene targeting studies cannot differentiate between the developmental
11 and adult, or systemic and central, effects of thyroid hormones.

12

13 The ventromedial hypothalamus (VMH) is a critical region of the brain involved in energy
14 homeostasis. TR β is the predominant TR isoform expressed in the VMH (Cook et al.,1992;
15 Barrett et al.,2007) and previous studies suggest that thyroid hormones acting in the VMH
16 regulate both food intake (Kong et al.,2004) and energy expenditure (Lopez et al.,2010).
17 Thus, we hypothesize that, in the VMH, TR β physiologically regulates food intake and body
18 weight. To investigate this hypothesis directly we used stereotaxic Cre-lox gene targeting to
19 generate a VMH-specific model of TR β knock down in adult mice.

20

21 **Results**

22 **Tissue specific knock down of TR β in the VMH in adult mice**

23 We knocked down TR β in the VMH of adult male mice using Cre-mediated excision of a
24 floxed critical exon in the *Thrb* gene. This approach enabled temporally and spatially
25 controlled reduction of TR β expression specifically in the VMH of adult mice. This model
26 eliminates the developmental consequences and abnormal systemic thyroid hormone levels
27 that occur in global TR β mutant mice (Ortiga-Carvalho et al.,2014) or in hypothyroid and
28 thyrotoxic animals (Ishii et al.,2003; Lopez et al.,2010).

1 The *Thrb*^{flox} allele contains loxP sites flanking exon 5 of *Thrb* (Winter et al.,2009) (Figure
2 S1A). *Cre-recombinase* mediated excision of this critical exon results in inactivation of *Thrb*
3 (Winter et al.,2009). *Cre recombinase* was introduced into the VMH of adult male *Thrb*^{flox/flox}
4 mice by stereotaxic injection of recombinant adeno-associated virus (rAAV) expressing a
5 Cre-GFP fusion protein to generate mice with reduced TR β expression in the VMH (VMH-
6 TR β ⁻) mice. *Thrb*^{flox/flox} mice injected with rAAV encoding GFP into the VMH (VMH-GFP) were
7 used as controls. Cre-mediated excision of the *Thrb*^{flox} allele was confirmed by PCR of DNA
8 from whole hypothalami of VMH-TR β ⁻ mice (Figure S1B). The *Thrb*^{flox} allele was not excised
9 in either the cerebellum or brainstem, indicating rAAV did not enter the ventricular system
10 following stereotaxic injection (Figure S1B). Fluorescence microscopy and *in situ*
11 hybridisation (*ISH*) both confirmed transgene expression localized to the VMH in both groups
12 of mice (Figure S2A,B). *ISH* using a probe specific for the floxed exon of *Thrb* demonstrated
13 reduced expression within the VMH of VMH-TR β ⁻ mice compared with controls (Figure
14 S2C,D).

15

16 **Selective knock down of TR β in the VMH in adult mice results in hyperphagia and** 17 **obesity**

18 VMH-TR β ⁻ mice consumed more food and gained more weight than controls (Figure 1A,B).
19 Weight gain in VMH-TR β ⁻ mice was three times greater than that of control mice by the end
20 of the study (Figure 1C,D).

21

22 Whole hypothalami for RNA-Seq analysis were collected from mice before significant
23 changes in body weight had occurred. This was so that changes in expression are likely to
24 be due to changes in thyroid hormone signalling rather than secondary effects of the
25 increase in body weight and food intake. Differential expression analysis was performed
26 (Table S1). Pathway analysis of differentially expressed genes revealed an over-
27 representation of genes involved in dopamine, growth hormone and leptin signalling
28 pathways, as well as genes that are involved in neuronal activity regulation including long-

1 term potentiation (LTP) and long-term depression (LTD), these results were qualitatively the
2 same when the FDR for analysis was set between 0.001 and 0.1 (Table S2). Among the
3 genes differentially expressed *Pomc* expression was decreased (log Fc -1.38, $p= 9.33 \times 10^{-7}$)
4 (Figure 1E) whilst *Npy* expression was increased (log Fc 0.7 $p = 9.42 \times 10^{-6}$) (figure 1F)
5 whilst that of *Thrb* was not altered at the level of the whole hypothalamus (Table S1).
6 Expression of *steroidogenic factor 1 (Sf-1)*, and *uncoupling protein-2 (Ucp-2)* both of which
7 are implicated in hypothalamic control of energy homeostasis (Majdic et al., 2002; Coppola
8 et al., 2007) were unchanged. The differentially expressed genes were compared to those
9 previously reported to be T3 responsive or directly regulated by T3 in cerebrocortical cells
10 (Table S1 and S2 and Figure S3) (Gil-Ibanez et al., 2017). Of the genes directly regulated by
11 T3 in cerebrocortical cells we identified 89 (approx. 15%) were also significantly changed in
12 our samples among which was *hairless (Hr)*. For genes regulated indirectly by T3 we
13 identified one-hundred and thirty three that were also changed (approx. 9%).

14
15 Total, visceral, subcutaneous, and epididymal fat mass were all increased in VMH-TR β ⁻ mice
16 compared to controls (Figure 2A-E). In keeping with the increased adiposity, VMH-TR β ⁻ mice
17 had a higher plasma leptin concentration than controls (Figure 2F).

18

19 **VMH-TR β ⁻ mice are systemically euthyroid**

20 Alterations in circulating thyroid hormones affect food intake and body weight (Pijl et
21 al., 2001). Measurement of plasma TSH, thyroxine (T₄) and T₃ confirmed that both VMH-TR β ⁻
22 and control mice were euthyroid (Figure S4A-C).

23

24 **VMH-TR β ⁻ mice are insulin resistant but do not show changes in the expression of 25 genes involved in hypothalamic glucose sensing**

26 Obese VMH-TR β ⁻ mice had high levels of fasting insulin (Figure S4D) as expected. However
27 when glucose tolerance and insulin tolerance were tested before the development of obesity
28 in the VMH-TR β ⁻ mice there were no differences between the VMH-TR β ⁻ and VMH-GFP

1 mice (Figure S4E,F). RNA-Seq analysis did not identify changes in expression of
2 hypothalamic glucose sensing genes.

3

4 **Obesity in VMH-TR β ⁻ mice is not due to TR β knock down in other brain areas**

5 To confirm that the observed weight gain and hyperphagia in VMH-TR β ⁻ mice resulted from
6 reduced TR β expression in the VMH and not spread through the ventricular system into
7 other brain regions, recombinant rAAV-Cre was injected into both lateral ventricles of
8 *Thrb*^{flox/flox} mice; a control group of mice were injected with rAAV-GFP. There was no
9 difference in cumulative food intake or body weight gain between these two groups (Figure
10 S4G,H).

11

12 **VMH-TR β ⁻ mice fail to mount an orexigenic response to administered T3**

13 In order to validate loss of T3 signalling following TR β inactivation in the VMH, we
14 administered T3 to VMH-TR β ⁻ and VMH-GFP mice by subcutaneous injection. Over the 24
15 hour study period, T3 significantly increased food intake in VMH-GFP mice but VMH-TR β ⁻
16 mice failed to mount an orexigenic response to the administered T3 (Figure S4I).

17

18 **VMH-TR β ⁻ mice do not become obese when pair-fed to the food intake of lean controls**

19 To investigate whether the hyperphagia contributed to, or was a consequence of, the
20 development of the obese phenotype, VMH-TR β ⁻ mice were pair-fed to the food intake of a
21 weight-matched VMH-GFP littermate for five weeks. During pair-feeding, there was no
22 difference in cumulative body weight change or food intake (Figure 3A,B) or locomotor
23 activity between the two groups.

24

25 After five weeks of pair-feeding, *ad libitum* access to food was restored for four weeks.
26 Following restoration of free feeding, VMH-TR β ⁻ mice gained significantly more weight and
27 consumed significantly more food than controls (Figure 3A,C).

28

1 **VMH-TR β ⁻ mice have reduced energy expenditure and reduced locomotor activity**

2 The contribution of changes in energy expenditure to the obese phenotype was investigated.
3 Oxygen consumption (VO₂), carbon dioxide production (VCO₂) and locomotor activity were
4 all decreased during the dark phase in *ad libitum* fed VMH-TR β ⁻ mice both before and after
5 the onset of obesity (Figure 4A-C). By contrast, there was no difference in VO₂, VCO₂ or
6 locomotor activity during the light phase (Figure 4A-C). The decrease in nocturnal
7 locomotion in VMH-TR β ⁻ mice was confirmed by behavioural analysis (Table S3). There was
8 no difference in respiratory exchange ratio (RER) (Figure 4D) and no difference in brown
9 adipose tissue (BAT) *uncoupling protein-1* (*Ucp-1*) expression (Figure 4E) between VMH-
10 TR β ⁻ and control mice. In addition, VMH-TR β ⁻ mice have a normal body temperature (Figure
11 S4J).

12

13 **Discussion**

14 These studies identify hypothalamic TR β as an important physiological regulator of appetite
15 and body weight. Reduced TR β expression in the VMH resulted in marked weight gain,
16 comparable to severe forms of monogenic obesity (Tecott et al.,1995; Yaswen et al.,1999).
17 The weight gain was a consequence of increased total body fat, and in particular a marked
18 increase in subcutaneous and visceral white adipose tissue, the latter being an important
19 risk factor for cardiovascular disease and diabetes (Montague and O'Rahilly, 2000).

20

21 VMH-TR β ⁻ mice ate more than control animals and pair-feeding studies indicated that
22 hyperphagia contributed directly to the obesity. Thus, VMH-TR β ⁻ mice remained lean when
23 food intake was restricted but rapidly became obese when *ad libitum* feeding was restored.

24

25 Selective TR β knock down specifically in the VMH was confirmed by *ISH* and fluorescence
26 microscopy. Although expression of *Thrb* was not reduced in the RNA-Seq analysis, these
27 samples are derived from whole hypothalami and therefore the decrease in the level in the
28 VMH is likely masked by the expression of *Thrb* throughout the rest of the sample. Indeed

1 the loss of TR β function in the VMH was demonstrated by the failure of the expected
2 orexigenic response to administered T3 in VMH-TR β ⁻ mice and further supported by the
3 appropriate changes in genes directly regulated by T3. The possibility of the phenotype
4 arising through virus spread to other CNS areas was excluded by rAAV-Cre injection into the
5 lateral ventricles, which did not result in hyperphagia or obesity.

6

7 Previous work in rats has reported the acute orexigenic effect of exogenously administered
8 T3 (Kong et al., 2004). Here we show the endogenous effect of thyroid hormone action
9 following selective TR β knock down. We suggest that our current work describes a local
10 circuit within the VMH that physiologically regulates food intake as distinct from the feeding
11 response to administered pharmacological doses of T3 analogous to the contrasting effects
12 of NPY and PYY.

13

14 To investigate the underlying cause of hyperphagia in VMH-TR β ⁻ mice, hypothalamic gene
15 expression patterns were determined by RNA-Seq. The expression of *Pomc* and *Fto* were
16 down-regulated in the hypothalamus, whilst *Npy* was upregulated. POMC and FTO are
17 thought to inhibit food intake whilst NPY stimulates food intake; therefore these changes in
18 expression may explain in part the phenotype observed.

19

20 Energy expenditure in VMH-TR β ⁻ mice was reduced both before and after the onset of
21 obesity. There was no difference in BAT *uncoupling protein-1* (*Ucp-1*) expression between
22 VMH-TR β ⁻ and control mice suggesting that adaptive thermogenesis was unaffected. It is
23 likely that changes in energy expenditure in VMH-TR β ⁻ mice resulted from decreased
24 locomotor activity. The reduced locomotor activity is not a consequence of the obesity since
25 it occurred before differences in body weight. In addition, during pair-feeding studies the
26 reduction in locomotor activity was lost, possibly due to food seeking behaviour. This is likely
27 to explain why body weight gain did not differ between the two groups before the restoration
28 of *ad libitum* feeding. The energy expenditure and pair-feeding data indicate that both

1 increased food intake and reduced locomotor activity contribute to obesity in VMH-TR β ⁻
2 mice.

3

4 In contrast to VMH-TR β ⁻ mice, global heterozygous TR β knockout mice do not have an
5 obese phenotype (Ortiga-Carvalho et al.,2014). This may be explained by the peripheral
6 hyperthyroidism of these mice. In addition, the appetite circuits within the hypothalamus are
7 subject to developmental plasticity and compensatory redundancy (Bouret et al.,2004;
8 Horvath, 2005). For example, neither global deletion of *Agrp* and/or *Npy* nor ablation of
9 arcuate AgRP/NPY neurons in neonatal mice results in a metabolic phenotype (Erickson et
10 al.,1996; Qian et al.,2002; Luquet et al.,2005), whereas ablation of these neurons in adult
11 mice produces profound hypophagia and starvation (Luquet et al.,2005; Gardiner et
12 al.,2005; Bewick et al.,2005). Similar developmental compensation may occur in global TR β
13 knockout mice.

14

15 Studies using adenovirus mediated expression of a dominant negative TR (DN-TR) in the rat
16 VMH have been reported (Lopez et al.,2010). Although, VMH DN-TR expression did not
17 affect food intake or body weight in euthyroid animals, it prevented weight loss in thyrotoxic
18 rats and resulted in reduced hypothalamic *AMP-activated protein kinase (Ampk)* expression
19 (Lopez et al.,2010). *Ampk* expression was unchanged in our model. DN-TR interferes with
20 the actions of both TR α and TR β and exerts a marked repressive effect on gene
21 transcription (Ortiga-Carvalho et al.,2014; Ferrara et al.,2012). By contrast, VMH-TR β ⁻ mice
22 have only reduced TR β activity rather than the pathological repression of TR target genes
23 that is present in animals expressing a dominant negative receptor. This fundamental
24 difference is likely to explain the contrasting phenotypes observed in these two models.

25

26 In summary, we have shown that hypothalamic TR β is an important physiological regulator
27 of energy homeostasis because TR β knock down in the VMH results in a phenotype of
28 hyperphagia and severe obesity that is comparable to some of the most extreme forms of

1 monogenic obesity (Tecott et al.,1995; Yaswen et al.,1999). Our findings provide insights
2 into the central regulation of energy homeostasis by TR β that could be a target for anti-
3 obesity therapies.

1 **Experimental Procedures**

2 **Animals**

3 *Thrb^{flox/flox}* mice (Winter et al.,2009) were genotyped by PCR using specific oligonucleotide
4 primers (Figure S1). Mice were housed in single cages and maintained under a
5 controlled environment (temperature 21–23 °C, 12-h light–dark cycle, lights on at
6 07:00) with *ad libitum* access to chow and water (RM1; SDS Diets), except where
7 stated. Male mice which were eight weeks old at the start of procedures were used
8 in all experiments. All animal studies were approved under the Animals (Scientific
9 Procedures) Act (1986) (Project License number 70_7229) and approved by the
10 Animal Welfare and Ethical Review Body, Imperial College London, which is signed
11 up to the ARRIVE guidelines.

12

13 **Recombinant AAV preparation**

14 Recombinant AAV was produced (Grimm et al.,1998) and isolated (Zolotukhin et al.,1999)
15 as previously described.

16

17 **Confirmation of rAAV transgene expression, *Thrb* excision and reduced TR β 18 expression in the VMH**

19 Excision of the *Thrb^{flox}* allele within the hypothalamus was confirmed by PCR (Figure S1).
20 *ISH* using a probe specific to the excised portion of TR β was performed to confirm reduced
21 TR β expression within the VMH (Smith et al., 2008).

22

23 **Measurement of energy expenditure**

24 Metabolic parameters were measured by indirect calorimetry using an open-circuit Oxymax
25 system of the Comprehensive Lab Animal Monitoring System (Columbus, OH, USA)
26 (Gardiner et al., 2010).

27

1 **RNA-Seq analysis**

2 RNA-Seq analysis was performed using hypothalamic RNA from VMH-GFP (n=3) and VMH-
3 TRβ⁻ (n=4) mice using Next Generation Sequencing (NGS) technologies (Imperial BRC
4 Genomics Laboratory, Imperial College London). For further details see Supplemental
5 Experimental Procedures.

6

7 **Statistical Analyses**

8 Cumulative food intake and body weight data were analyzed using generalized estimating
9 equations with exchangeable correlation matrix and robust standard errors. Differences
10 between two groups at individual time points were analyzed by unpaired t-tests, for multiple
11 comparisons a Bonferroni correction was applied. Values from the behavioural study were
12 analyzed using a one way ANOVA followed by Kruskal-Wallis test. Data from the energy
13 expenditure test were analyzed using a one way ANOVA followed by a Newman-Kuels test.
14 Plasma thyroid hormones were compared using Mann-Whitney U test. Differences between
15 groups were considered statistically significant at the 95% confidence level (P<0.05).

16

1 **Author Contributions**

2 SH, MP, WSD, SAR, YM, CH, WF and JVG conducted the majority of the experiments. SH,
3 WSD, SRB, JHDB, GRW and JVG wrote the manuscript. SAR and AG maintained the mice.
4 AG and JHDB prepared the TR β probe. JB and JA performed the MRI study. GSHY, BYHL
5 and JPW performed the RNA-Seq experiments and analysis, JS generated the *Thrb*^{flox/flox}
6 mice. WSD, SRB, JHDB, GRW and JVG conceived of and supervised the project. All
7 authors discussed the results and commented on the manuscript.

8

9 **Accession numbers**

10 The accession number for the RNA-Seq data reported in this paper is GEO: GSE98690

11

12 **Acknowledgements**

13 We thank Dr Roy Weiss, Dr Samuel Refetoff and Dr XiaoHui Liao (University of Chicago) for
14 measurement of tT3, tT4 and TSH concentrations. This work is funded by the BBSRC
15 BBIF021704. Investigative Medicine is funded by grants from MRC, BBSRC, NIHR, an FP7-
16 HEALTH- 2009- 241592 EuroCHIP grant and the NIHR Imperial Biomedical Research
17 Centre. SH receives a MRC CRTF, an NIHR CL and a Society for Endocrinology ECG. WSD
18 is funded by an NIHR Research Professorship. GRW and JHDB are supported by a
19 Wellcome Trust Strategic Award (101123/Z/13/A), Wellcome Trust Investigator Award
20 (110141/Z/15/Z & 110140/Z/15/Z), EU HORIZON 2020 Grant (THYRAGE-666869) and MRC
21 funding (MR/N01121X/1). This work used the computing resources of the UK MEDical
22 BIOinformatics partnership - aggregation, integration, visualisation and analysis of large,
23 complex data (UK MED-BIO) which is supported by the MRC [grant number MR/L01632X/1].
24 University of Cambridge Metabolic Research Laboratories are supported by the UK Medical
25 Research Council (MRC) Metabolic Disease Unit (MRC_MC_UU_12012/1 and

- 1 MRC_MC_UU_12012/5), a Wellcome Trust Strategic Award (100574/Z/12/Z) and the
- 2 Helmholtz Alliance ICEMED.

Supplemental Data Items

Figure S1 Schematic representation of the *Thrβ^{flox}* allele and verification of excision of the *Thrβ^{flox}* allele related to figure 1

A) Genomic structure of *Thrβ* (NC_000080.6 (17660960-18038088)) showing the locations of the thyroid hormone receptor beta 1 (*TRβ1*: NM_001113417.1) and beta 2 (*TRβ2*: NM_009380.3) isoforms. White boxes represent untranslated exons, shaded boxes indicate unique 5' *Thrβ1* exons, the black box shows the unique 5' *Thrβ2* exon, and the light grey boxes show the 6 exons common to both isoforms. The positions of the two LoxP sites flanking exon 5 are indicated by the white triangles. The wild type and *Thrβ^{flox}* alleles were amplified using the forward (F1: 5'-CAGCCACTGGAAGCAGAAG-3') and reverse primers (Rc: 5'-AACGTCACTGTTGTGGTGTACAGG-3'). PCR amplification of the wild type allele resulted in a 931bp product whereas the product of the *Thrβ^{flox}* allele was 1111bp in size. The excised *Thrβ^{flox}* allele was amplified using the forward primer (F2: 5'-CATCTATGTTGGCATGGCAACAGACT-3') and reverse primer (Rc) the resulting product being 601bp in size.

B) Agarose gel visualized under UV illumination of PCR on DNA to demonstrate excision of the *Thrβ^{flox}* allele in *Thrβ^{flox/flox}* mice, restricted to the hypothalamus, following intra-VMH injection of rAAV-Cre. Arrows donate position of *Thrβ^{flox}* allele (1111bp), wildtype allele (931bp) and the excised *Thrβ^{flox}* allele (601bp). Lane 1: HyperLadder I™ (DNA molecular weight marker). Lanes 2 and 5: hypothalamic DNA from two *Thrβ^{flox/flox}* mice injected with rAAV-Cre into the VMH, denoted as VMH-TRβ⁻ mouse 1 and VMH-TRβ⁻ mouse 2 respectively, each showing a band at 1111bp representing the *Thrβ^{flox}* allele and a band at 601bp representing the excised *Thrβ^{flox}* allele. Lanes 3 and 6: PCR performed on DNA extracted from the cerebellum (lane 3, VMH-TRβ⁻ mouse 1; lane 6, VMH-TRβ⁻ mouse 2). Lanes 4 and 7: PCR performed on DNA extracted from and brainstem (lane 4, VMH-TRβ⁻ mouse 1; lane 7, VMH-TRβ⁻ mouse 2). In these lanes only the band at 1111bp representing the *Thrβ^{flox}* allele is present. The absence of a band at 601bp in these lanes demonstrates that the *Thrβ^{flox}* allele has not been excised in these extra-hypothalamic brain tissues. Lanes 8 and 11: hypothalamic DNA from two *Thrβ^{flox/flox}* mice injected with rAAV-GFP into the VMH, denoted as VMH-GFP-mouse 1 and VMH-GFP-mouse 2 respectively, each showing a band at 1111bp representing the *Thrβ^{flox}* allele. The absence of a band at 601bp in these lanes demonstrates that the *Thrβ^{flox}* allele has not been excised in the hypothalami of the rAAV-GFP injected mice. Lanes 9 and 12: PCR performed on DNA extracted from the cerebellum (lane 9, VMH-GFP-1-mouse 1; lane 12, VMH-GFP-mouse 2). Lanes 10 and 13: PCR performed on DNA extracted from the brainstem (lane 10, VMH-GFP-mouse 1; lane 13, VMH-GFP-mouse 2). Lane 14: PCR of DNA extracted from the hypothalamus of a *Thrβ^{flox/flox}* mouse injected with rAAV-Cre. Lane 15: PCR of DNA extracted from the hypothalamus of an un-injected *Thrβ^{flox/flox}* mouse. Lane 16: PCR of DNA extracted from the hypothalamus of a wildtype mouse. Lane 17: negative control (autoclaved glass distilled water). Lane 18: HyperLadder I™ (DNA molecular weight marker).

Figure S2 Localization studies, verification of rAAV-Cre transgene expression and excision of the $TR\beta^{fllox}$ allele within the ventromedial hypothalamus related to figure 1

(A) GFP fluorescence within the VMH which sits adjacent to the third ventricle (3V) (scale bar represents $6\mu\text{m}$). (B) Representative *in situ* hybridization image of a VMH- $TR\beta^{-/-}$ mouse brain radio-labelled with woodchuck hepatitis post-regulatory element (WPRE) antisense riboprobe which localizes transgene expression to the VMH. The WPRE sequence is part of the expression cassette of rAAV vectors but is not endogenously expressed by mammalian cells. Its detection therefore confirms successful rAAV neuronal infection and transgene expression. Scale bar is 0.2mm (C) Representative *in situ* hybridization image of a VMH-GFP mouse brain radio-labelled with $TR\beta$ antisense riboprobe showing expression of $TR\beta$ within the VMH (hashed area). This is in comparison to the *in situ* hybridization image (D) showing a VMH- $TR\beta^{-/-}$ mouse brain radio-labelled with *Thrb* antisense riboprobe. The lack of riboprobe binding in the VMH- $TR\beta^{-/-}$ mouse brain (D) (area marked by hashed lines) in comparison to the control brain (C) suggests reduced expression of $TR\beta$ in the VMH of VMH- $TR\beta^{-/-}$ mice. Scale bar $25\mu\text{m}$.

Figure S3: Venn diagram of comparison of differentially regulated genes in VMH-TR β ⁻ mice and those reported to be T3 sensitive in cerebrocortical cells and heat map of significantly altered genes directly regulated by T3 related to figure 2

RNA was extracted from hypothalami from VMH-GFP (n=3) and VMH-TR β ⁻ (n=4) mice and subject to RNA seq analysis.

A. Significant differential expression genes were compared to those reported by Gil-Ibañez al 2017.

B. Significant differential expression genes were compared to those reported by Gil-Ibañez al 2017 and shown are the 93 genes reported to be directly regulated by T3 that were significantly altered in our samples.

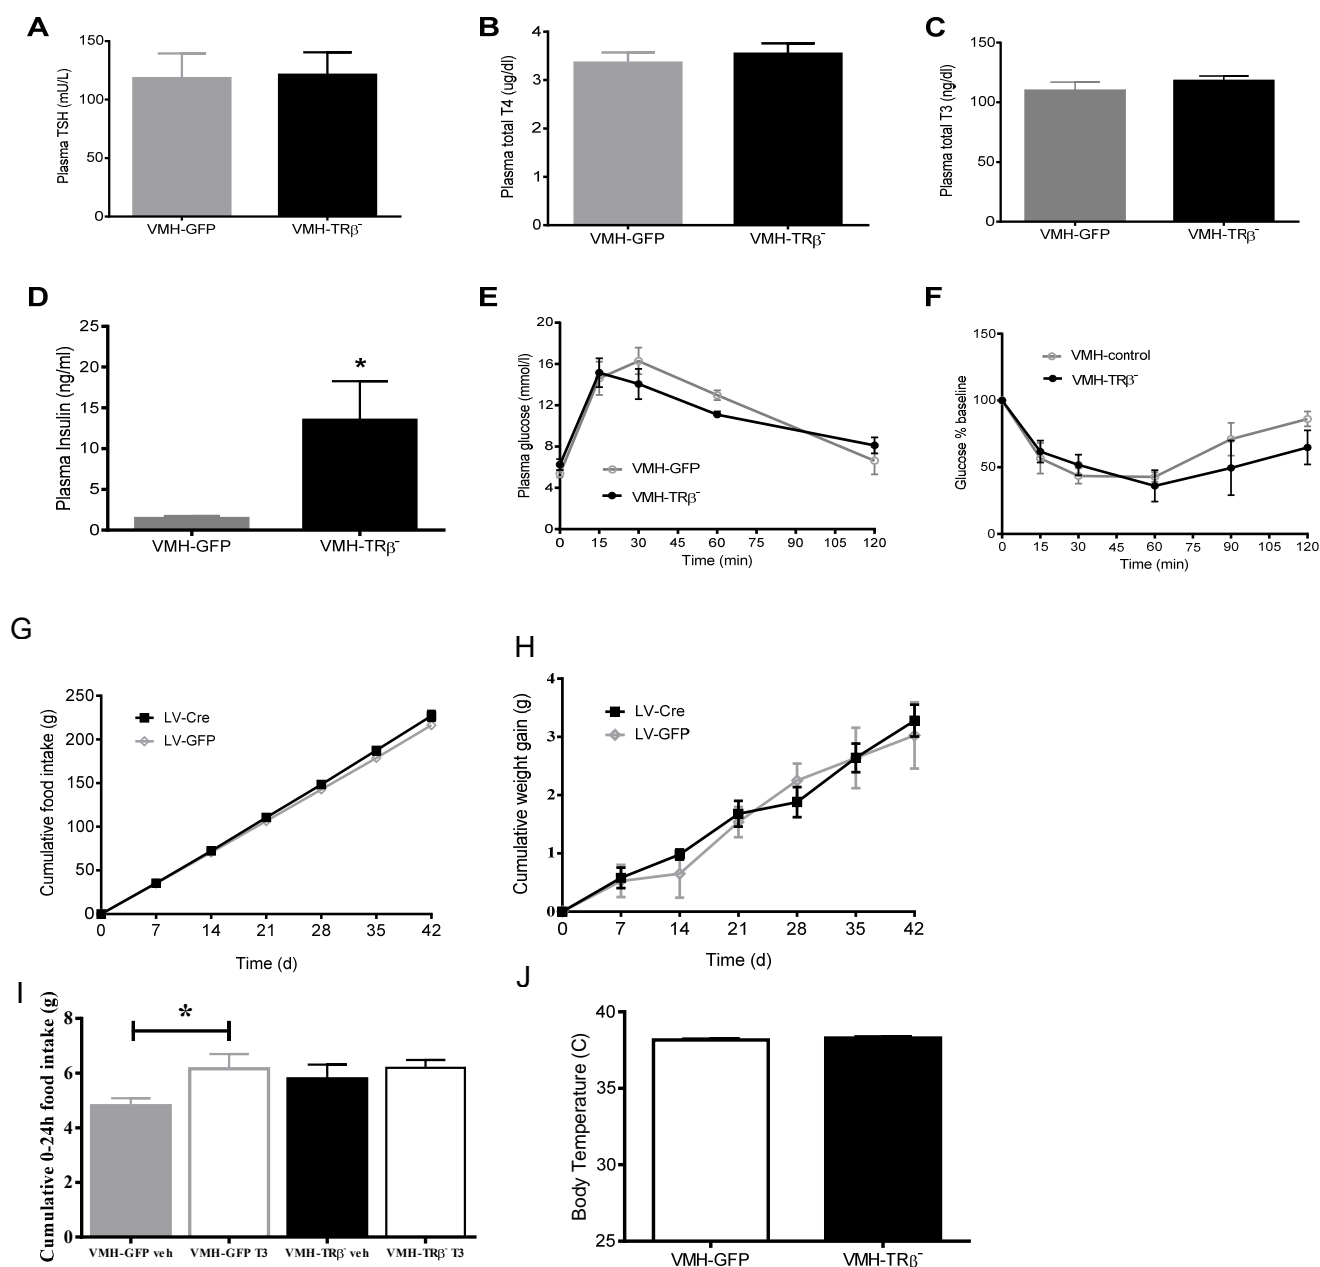

Figure S4: Systemic thyroid function and glucose homeostasis body temperature and response to exogenous T3 injection of VMH-TR β^{-} and VMH-GFP and effect of lateral ventricle injection of rAAV-Cre (LV-Cre) or rAAV-GFP (LV-GFP) into the lateral ventricles (LV) of *Thr β ^{flox/flox}* mice related to figure 2

(A) Plasma mTSH.

(B) Plasma total T4.

(C) Plasma total T3.

(D) Fasting plasma insulin.

(E) Glucose tolerance test performed before development of obesity in mice.

(F) Insulin tolerance test performed before development of obesity in mice.

(G) Weight change in LV-Cre and LV-GFP mice

(H) Cumulative food intake in LV-Cre and LV-GFP mice

(I) Twenty-four hour food intake in VMH-GFP or VMH-TR β^{-} mice in response to exogenous T3 or vehicle.

(J) Body temperature in VMH-TR β^{-} and VMH-GFP mice.

Results (A-C) are mean \pm s.e.m. (n=7 per group). Data were analyzed by Mann-Whitney U test.

Results D are mean \pm s.e.m. (n=10 per group). Results E-F are mean \pm s.e.m. (n=9 per group).

Results G and H are mean \pm s.e.m. (n=8-10 per group). Data were analyzed using generalized estimating equations with exchangeable correlation matrix and robust standard errors

Results I are mean \pm s.e.m (n=5-7 per group) Results J are mean \pm s.e.m (n=4 per group) Data were analyzed by t-test.

	Dark phase		Light phase	
	VMH-GFP	VMH-TR β ⁻	VMH-GFP	VMH-TR β ⁻
Feeding	19 (16-23)	21 (9-25)	14 (13-17)	9 (9-14)
Drinking	2 (0-3)	0 (0-0)	0 (0-1)	0 (0-0)
Grooming	24 (22-26)	17 (11-24)	15(10-19)	13 (4-16)
Burrowing	1 (0-2)	1 (0-3)	3 (0-4)	6 (1-8)
Rearing	2 (0-3)	0 (0-1)	0 (0-0)	0 (0-0)
Locomotion	21 (17-22)	11 (7-13)**	9 (7-10)	6 (3-8)
Sleep	24 (19-24)	36 (32-41)	60 (42-65)	60 (48-68)
Head down/still	17 (11-21)	21 (13-32)	10 (3-15)	15 (13-18)

Table S3 Effect of TR β inactivation in the VMH on mouse behavior related to figure 4. At least twenty eight days after rAAV injection, behavioral patterns were monitored continuously for sixty minutes at 08.30h, 12.30h, 16.30h, 19.30h, 00.00h and 04.00h by observers blinded to the experimental treatment. At every time point, each animal was observed for three five second periods every five minutes and the behavior noted. There was a significant reduction in nocturnal locomotor activity in VMH-TR β ⁻ compared with the control group. There was no difference in abnormal behaviors (defined by a significant increase in head down, burrowing or rearing) between VMH-TR β ⁻ and control mice. Results are median (interquartile range) (n=7-10 per group); ** $P < 0.01$ versus control data were analyzed by Kruskal-Wallis one way analysis of variance.

Supplemental Experimental Procedures

Stereotaxic surgery

Stereotaxic surgery was performed on eight week old male *Thrb^{flox/flox}* mice (Gardiner et al., 2005). The VMH injection coordinates were 1.3mm posterior, 0.4mm lateral and 6mm ventral. The LV coordinates were 0.5mm posterior, 1.1mm lateral and 2.4mm ventral. Each mouse received a 0.5 μ l bilateral injection of either rAAV-Cre 7.63×10^{13} gp/ml or rAAV-GFP, 8.57×10^{13} gp/ml. Mice were individually housed at 21-23°C with a 12-h light/dark cycle with *ad libitum* access to food (RM1 diet; DS, Witham, UK) and water unless otherwise specified.

RNA seq analysis

RNA-Seq analysis was performed using hypothalamic RNA from VMH-GFP (n=3) and VMH-TR β - (n=4) mice using Next Generation Sequencing (NGS) technologies (Imperial BRC Genomics Laboratory, Imperial College London). TruSeq Stranded mRNA libraries were multiplexed and sequenced with the average of 40 million DNA fragments per sample (100 bp paired-end reads). Quality control was performed using FastQC software (version 0.11.2). Sequencing reads were aligned to GRCm38 reference mouse genome by Tophat (version 2.0.10) using the set of known genes provided by Ensembl database (release 75) with the average alignment rate of 85%. The raw number of read pairs mapped to each Ensembl gene was calculated with HTSeq (version 0.6.0) in 'union' mode. Reads (or read pairs) that overlap more than one gene or mapped to multiple locations were discarded. Differential expression analysis was performed using EdgeR and an FDR cutoff of 0.05 was used to generate the lists of DE genes. The lists of T3 responsive genes and direct T3 responsive genes were obtained from Gil-Ibañez et al. 2017 and overlapped with DE expressed genes from the present study. Ingenuity Pathway Analysis was performed using the resultant sets of DE genes. A heatmap comparing gene expression in 89 direct T3 responsive genes in the present study was generated using GeneSpring.

Quantitation and distribution of white adipose tissue by MRI

VMH-TR β ⁻ and VMH-GFP mice (n=3 per group) were scanned using a 4.7 Tesla Varian INOVA imaging system. SliceOmatic software (version 4.2) was used to separate and quantify tissue volumes (Mystkowski et al., 2000). Quantitation of fat depots was normalized to total body fat and total body fat was normalized to body weight.

Glucose and insulin tolerance tests

Glucose and insulin tolerance tests were carried out as previously described (Bewick et al., 2009). Plasma glucose was measured using the Acensia Contour blood glucose monitoring system (Bayer HealthCare, Newbury, U.K.).

Peripheral (subcutaneous) administration of T3 (75nmol/kg) and food intake

In a randomized crossover, VMH-TR β ⁻ mice and VMH-GFP mice control mice (n=5-7 per group) received either subcutaneous T3 (75nmol/kg) or vehicle as previously described (Kong et al., 2004) and food intake measured.

GFP visualization

Animals were terminally anaesthetized and the brains dissected, incubated and sliced as previously described (Gardiner et al., 2005). Fluorescence was detected by a Zeiss deconvoluting microscope (Axiovert S100 TV, Carl Zeiss, Jena, Germany) using a FITC filter. Images were acquired using a MetaMorph imaging system (Universal Imaging, West Chester, USA) as previously described (Gardiner et al., 2005).

Pair-feeding of VMH-TR β ⁻ mice to the food intake of VMH-GFP mice

Twenty eight days after rAAV injection, VMH-TR β ⁻ mice were pair-fed to the mean daily food intake of a weight matched VMH-GFP litter mate (n=9 per group). After 5 weeks of pair-feeding, *ad libitum* feeding was re-instated for a further 4 weeks.

Plasma assays

Total T4, T3 and TSH were measured by radioimmunoassay (RIA) (Pohlenz et al., 1999). Fasting leptin and fasting insulin were measured by enzyme linked immunosorbent assay (Crystal Chem, IL).

Quantitation of *Ucp1* mRNA expression in BAT by northern blot analysis

RNA was extracted from inter-scapular BAT of VMH-TR β ⁻ and VMH-GFP mice (n=7-11 per group) and *Ucp1* mRNA expression determined by northern blot analysis as previously described (Smith et al., 2008).

Measurement of energy expenditure

The study commenced 21 days after rAAV injection. One week and 6 weeks into the study, metabolic parameters were measured for 24h (12h light phase, 12h dark phase) by indirect calorimetry using an open-circuit Oxymax system of the Comprehensive Lab Animal Monitoring System from Columbus Instruments (Columbus, OH, USA). Animals (n=5-6 per group) were maintained at 21-23°C with a 12-h light/dark cycle with *ad libitum* access to food (RM1 diet; DS, Witham, UK) and water. To measure oxygen consumption and carbon dioxide production exhaust air from each tight chamber was sampled for 1min at 30min intervals. Oxygen consumption and carbon dioxide production were normalized to surface area (Tschop et al., 2011) (body weight to the power of 0.75). The ambulatory activity of each animal was assessed simultaneously using the optical beam technique as previously described (Gardiner et al., 2010).

Behavioral Analysis

At least 28 days after rAAV injection, behavioral patterns of VMH-TR β and VMH-GFP mice (n=7-10 per group) were monitored continuously for sixty minutes at 08.30h, 12.30h, 16.30h, 19.30h, 00.00h and 04.00h, by observers blinded to the experimental treatment. At every time point, each animal was observed for three, five second periods every five minutes and the behavior noted. Behavior was classified into eight categories: feeding, drinking, grooming, burrowing, rearing, locomotion, sleep, head down/still as previously described (Fray et al., 1980; Abbott et al., 2001). Abnormal behavior was defined by a significant increase in head down, burrowing or rearing as previously described (Abbott et al., 2001).
