Cover illustration

Coverage of stream sediment and stream organic surveys in FOREGS countries.

This report was prepared by the FOREGS Geochemistry Task Group for the annual general meeting of FOREGS Directors September 1996. The report, which details the current status of geochemical mapping in FOREGS countries was also prepared as a contribution to the International Union of Geological Sciences Working Group on Continental Geochemical Baselines.

BRITISH GEOLOGICAL SURVEY

The full range of Survey publications is available from the BGS Sales Desk at the Survey headquarters, Keyworth, Nottingham. The more popular maps and books may be purchased from BGS-approved stockists and agents and over the counter at the Bookshop, Gallery 37, Natural History Museum (Earth Galleries), Cromwell Road, London. Sales desks are also located at the BGS London Information Office, and at Murchison House, Edinburgh. The London Information Office maintains a reference collection of BGS publications including maps for consultation. Some BGS books and reports may also be obtained from HMSO Publications Centre or from HMSO bookshops and agents.

The Survey publishes an annual catalogue of maps, which lists published material and contains index maps for several of the BGS series.

The British Geological Survey carries out the geological survey of Great Britain and Northern Ireland (the latter as an agency service for the government of Northern Ireland), and of the surrounding continental shelf, as well as its basic research projects. It also undertakes programmes of British technical aid in geology in developing countries as arranged by the Overseas Development Administration.

The British Geological Survey is a component body of the Natural Environment Research Council.

FOREGS Geochemistry Task Group Members

1994–1996

Task Group:

Prof Jane A Plant, British Geological Survey, UK (CHAIR)
Dr Gerard Klaver, Rijks Geologische Dienst, The Netherlands
Mr Juan Locutura, Instituto Technologico Geominero, Spain
Prof Reijo Salminen, Geological Survey of Finland
RNDr Kamil Vrana, Geological Survey of the Slovak Republic

Scientific secretariat:

Ms Fiona M Fordyce, British Geological Survey, UK

Acknowledgements

The FOREGS Geochemistry Task Group thank the FOREGS Directors, under the Chairmanship of Dr P McArdle (Republic of Ireland), for the opportunity to prepare this inventory. The Directors of surveys in Finland (Dr V Lappalainen), The Netherlands (Dr C Staudt), Slovakia (RNDr P Grecula), Spain (Dr C Caride) and the UK (Dr P J Cook) are especially thanked for making resources available. We also thank the Survey geochemists throughout the FOREGS countries for supplying the comprehensive data contained in the report. The institutes which have provided information are listed in Appendix 2 of this report. The Geological Surveys of The Netherlands, Finland and the UK kindly hosted task group meetings. Dr H W Haslam, Dr N Breward, Ms D M A Flight and Mr D L Miles are thanked for their constructive comments on the inventory form and the text of the report.

1 Introduction

1.1 The Problem

1. Europe has a long history of mining, industrialisation, intensive agriculture/forestry and urbanisation. It remains one of the most densely populated and utilised land areas on earth.
2. These factors have led to interrelated problems of land degradation and contamination which affect both the land and the coastal zone.
3. Deficiency conditions in crops, agricultural animals and possibly man are increasing, partly as a result of land degradation.
4. Redevelopment of contaminated land is becoming increasingly difficult because of legislative and fiscal controls. This is despite the need to reutilise 'brown field' sites rather than extend development into 'green field' areas.
5. Throughout Europe public concern about the environment is growing. In response, national governments and the European Union (EU) are attempting to develop policies, legislation and infrastructure, such as the European Environment Agency (EEA). Attempts are also being made to establish 'Safe Levels' of Potentially Harmful Elements and Species (PHES), but these are often based on limited and/or inadequate information.
6. The available data on environmental geochemical baselines and radioactivity are not systematic in coverage or quality and, therefore, are not of the standard required to quantify the distribution of PHES at the European scale as a basis for policy-making and monitoring future change to the environment.

1.2 Current Status

1. At the present time, knowledge of the geochemistry of the surface environment of Europe is based on different surveys of variable standards carried out by different organisations in the public and private sectors. Whilst there are exceptions, Geological Surveys have, in the past, provided data on rocks and stream sediments; Soil Surveys on soils; Hydrological Surveys on ground and surface water and biologists/agriculturists on plant and animal tissue samples.
2. In general, there is a failure to recognise that the natural geochemical background is highly variable and that natural levels of PHES (such as As, Cd, Pb, NO₃, the radioelements and organic pollutants) can be as high or higher than those caused by man-made sources of pollution. Even where synthetic pollutants are concerned, it is the natural geology and geochemistry which frequently exert the fundamental controls on the distribution of the PHES and consequently determine their potential to create hazards.

1.3 Requirements

Systematic baseline environmental geochemical data are necessary to inform policy-makers and provide a sound basis for legislation. For this purpose such data are required to be:

1. Standardised across national boundaries.
2. Available in digital form for use on GIS so that they can be viewed interactively with other datasets, such as those for land-use and for animal and human morbidity and mortality data.
3. Comprehensive, to include the majority of PHES and ideally as many harmful chemical species as possible, including synthetic compounds.
4. Based on a full suite of sample types including soil, stream sediment, surface water, groundwater and offshore marine and estuarine sediment in the coastal zone.

1.4 Why Geological Surveys?

1. The lithosphere is the fundamental base on which soils and crops develop and through which water and fluid pollutants migrate.
2. Geological Surveys are uniquely well equipped to prepare the systematic environmental geochemical baseline databases required for Europe, since:
 - a. They have the knowledge and experience of optimum methods of sampling and analysing surface environmental materials and are familiar with the preparation, analysis and interpretation of geochemical maps.
 - b. Many are already concerned with the preparation of multi-element geochemical maps of rocks, soils, surface waters, groundwaters and stream sediments.
 - c. Many are centres of excellence for the study of water and silicate mineral chemistry. The aim is to standardise all surveys at a high level of analytical capability.
 - d. Geochemical baseline data in digital form produced by FOREGS countries at the national scale already enable contaminated land to be viewed in the context of naturally occurring high levels of PHES and the natural environment generally.
 - e. The FOREGS countries generally have programmes concerned with site-specific pollution such as landfill and nuclear waste repositories, hence have considerable knowledge of the interaction of natural and synthetic pollutants with the natural environment.

- f. Geological Surveys have experts on ore deposits, which provide natural analogues for understanding the distribution and migration of heavy metals, radioelements and other pollutants in different geological environments.
- g. The European Geological Surveys have the quality control procedures in place and the expertise in databases and GIS to develop and apply environmental baseline geochemistry effectively.

1.5 Geochemical Information in FOREGS Countries

The inventory described in this report has been prepared on behalf of the FOREGS Directors to identify the similarities and differences among different national datasets and to delineate areas where data are currently unavailable.

This information forms a fundamental basis for compiling a series of geochemical maps of Europe with the primary aim of informing environmental policy-makers. Such maps would also be of value for geological and metallogenetic studies, agriculture, forestry, veterinary studies, epidemiology, and, in the coastal zone, fisheries.

The inventory was also carried out as a contribution to the IUGS Working Group on Continental Geochemical Baselines.

2 The Survey

Information was collected using a standard form designed by the FOREGS Geochemistry Task Group. The form comprised 9 sections, each for a particular sample type (Table 1). An example of the drainage sediment survey section is shown in Appendix 1. Detailed information on collection, preparation, analysis and data availability were requested for all sample types with the exception of rock and biological surveys where information on availability only was required. The form was distributed to the organisations detailed in Appendix 2. Mining and exploration companies and universities were generally not included because the surveys which they carry out tend to cover relatively small areas of less than 5000 km², the lower limit considered relevant for the purpose of the inventory. Completed forms were received from 29 of 33 countries (Figure 1). Croatia, Iceland, Latvia and Switzerland have not conducted regional geochemical surveys over the minimum area required for the survey. Results for Sardinia and

for Scottish soils were received too late to be included in the calculations presented in this report. Bulgaria has recently joined the FOREGS group and information from Bulgaria will be included in the digital version of the inventory. Unfortunately it was not possible to represent Greenland on the map projections presented in this report. Maps indicating survey areas in Greenland are included separately in Appendix 3. In general, the form was completed successfully although the recording of UTM coordinates for the boundaries of survey areas presented some difficulties. The coordinates held in the inventory are, therefore, a mixture of UTM coordinates, latitude and longitude and local coordinates.

Summary information is presented here in tables, maps and statistical diagrams. Copies of the inventory are available to participating organisations in digital format in Microsoft Excel (IBM or Macintosh) from the BGS.

Table 1 Sample types included in the FOREGS geochemical inventory.

Form Section	Sample Type	Information Required

tions, although surveys carried out in France, Greenland and Spain were primarily for mineral exploration (Appendix 4).

Surface water surveys covering nearly one fifth of the FOREGS region have generally involved the collection of stream water, although spring and lake water have also been sampled, particularly in Central Europe (Table 2; Figures 2 and 7 and Appendix 4). Multi-element analysis is available for surveys covering most of the Czech Republic, former West Germany, Poland, Slovakia and Slovenia and for extensive areas of Finland, Norway, Romania and the UK. In addition, data for U, are available for Albania, Greenland and northern UK (Appendix 4).

Soils have been collected in 16 of the 33 countries, covering 11% of the FOREGS region (Table 2 and Figures 2 and 3). Belgian, German, Slovenian and Ukrainian surveys have sampled A, B and C horizon soils whereas, Slovakian surveys are based on the collection of A and C horizon soils only. Surveys in the Czech Republic, Estonia, Lithuania, The Netherlands, Norway, Portugal and the UK are based on the collection of A horizon soils although some surveys in the Czech Republic and the UK also sample B horizon soils. Surveys in Albania and France are based on the collection of B horizon soils only.

3.2 Sampling Density

A wide range of sampling densities have been employed across the FOREGS region, reflecting different survey objectives. Stream sediment survey densities range from 1 sample per $<0.5 \text{ km}^2$ in France, Greece, Italy, Portugal and Spain for mineral exploration to 1 sample per 200 km^2 in Fennoscandia for geological and metallogenic province mapping, to 1 sample per 2000 km^2 in Romania for rapid reconnaissance mapping (Table 3 and Appendix 4). Most surveys, however, have been carried out in the range of 1 sample per 1 km^2 to 1 sample per 5 km^2 (Table 3 and Appendix 4).

Surface water surveys range from relatively high densities (<1 sample per 2.5 km^2 in Albania, Germany and the

UK) to very low densities in Finland and Romania (1 sample per 290 km^2 and 1 sample per 2000 km^2 respectively).

In general, soil survey sampling densities follow similar trends to those of stream sediments ranging from 1 sample per $<1 \text{ km}^2$ in France and Portugal to 1 sample per 3500 km^2 in Estonia. Most soil surveys have been conducted in the range 1 sample per 5 km^2 to 1 sample per 25 km^2 .

3.3 Size Fractions

The size fractions analysed for the different stream sediment surveys range from $<63 \mu\text{m}$ (BSI 240 mesh) in the Czech Republic, Romania and Slovenia to $<1000 \mu\text{m}$ (BSI 16 mesh) in Lithuania (Table 4 and Appendix 4). Most stream sediment surveys have, however, been based on the collection and analysis of <177 to $<200 \mu\text{m}$ (BSI 80 to 76 mesh) fractions (Figure 8 and Appendix 4).

All the filtered surface water analyses carried out in the FOREGS region have been based on a filter size of $0.45 \mu\text{m}$ with the exception of Poland where a hard filter was used (Figure 9, Table 4 and Appendix 4).

The range of grain-size fractions collected for soil surveys is bimodal. Some countries collect <100 to $<180 \mu\text{m}$ (BSI 150 to 85 mesh) fractions to integrate with stream sediment surveys, while others follow traditional soil survey practice and use <1000 or $<2000 \mu\text{m}$ (BSI 16 or 8 mesh) fractions (Table 4, Figure 9 and Appendix 3).

3.4 Sieving Techniques

Several countries had difficulty completing the section of the inventory on sieving methods. In some cases it is not clear whether samples were sieved in the field, in the laboratory or both (Table 5). The majority of stream sediment surveys employ sieving techniques in the laboratory after the samples have been dried, but in a significant number of countries sediment is wet sieved in the field. Surveys in Norway and a small area in the north of the UK are based on wet sieving sediment to a relatively coarse size fraction

3 Results

3.1 Regional Coverage

The extent of coverage of FOREGS countries by each sample type is listed in Appendix 4 and is shown in Figures 2 to 7 and Appendix 3. Results for percentage of coverage are based on the total area of the 33 FOREGS countries which extend to 8 306 516 km². Table 2 lists the range of sample types collected by each country.

The coverage of regional geochemical till, organic drainage, rock, lake sediment and biological surveys is largely restricted to Scandinavian, Baltic and some central European countries (Table 2 and Figures 2–6). These surveys do not, therefore, provide a suitable basis for the preparation of European geochemical maps. The use of overbank sediment is also somewhat restricted (Table 2 and Figures 2 and 4). Although the coverage of heavy mineral surveys is more extensive (12%) (Table 2 and Figures 2 and 4), in several cases these samples have undergone qualitative rather than quantitative analysis and are consequently not suitable for the preparation of geochemical maps. Despite increased concern about radioactivity in the environment, only 18% (Table 2 and Figures 2 and 5) of

the FOREGS region is covered by radiometric surveys. This contrasts with the situation in North America and Australia where complete coverage of systematic radiometric data is available. There is clearly a need for survey organisations to increase radiometric survey activity if they are to make a significant contribution to environmental radiometric policy.

Many FOREGS countries have surveys based on either stream sediments, surface waters or soils and these materials are considered in more detail in this report as they appear to offer the most valuable basis for the preparation of European geochemical maps. Stream sediment surveys are by far the most extensive and have been carried out in 22 of the 33 countries covering 26% of the FOREGS region (Table 2 and Figures 2 and 6). Complete systematic coverage is available for Albania, Northern Fennoscandia, former West Germany, Lithuania, Poland, Slovakia and Slovenia. Large areas of Austria, the Czech Republic, France, Greece, Greenland, Portugal, Romania and the UK are also covered. Most of these surveys have been carried out for a range of environmental and economic applica-

in the field followed by dry sieving to a finer mesh size in the laboratory. With the exception of Belgium and the Ukraine, all soil surveys are based on dry sieving methods. Estonia and Cyprus are the only countries to dry sieve soils in the field.

3.5 Analytical Techniques

A range of techniques have been employed to analyse geochemical samples in FOREGS countries, largely reflecting the years during which the survey was conducted. The abbreviations used to describe each technique are listed in Table 6. The main analytical methods available in FOREGS countries include XRF, ICP-AES, ICP-MS, DC-Arc ES, Flame AAS and NAA (Table 7 and Appendix 4). Surveys in Ireland, Italy and Luxembourg do not have the facilities to analyse regional geochemical samples, and geochemical analyses were carried out in

commercial and survey laboratories in other countries in these cases.

The range of elements determined appears to reflect the type of analytical method available rather than the economic or environmental aims of the survey (Figures 10–12 and Appendix 4). Elements such as Sr and Zr which are readily determined by rapid, high-productivity, cost-effective methods have been included in more surveys than elements such as Au and U which are potentially of greater economic significance. There are few data for elements of environmental importance which are difficult to determine by automated analytical methods. Iodine has been determined in only one water survey, for example, and only Greenland, Norway, Slovakia and the UK have data for Se in stream sediments, surface waters or soils. Both total and extractable analytical methods have been employed. The definitions listed in the inventory are those described by each survey organisation.

Table 6 Abbreviations of analytical techniques employed by FOREGS countries.

Analytical Technique	Abbreviation
DC Arc Emission Spectrometry	DC-Arc ES
Flame Atomic Absorption Spectrometry	Flame AAS
Electro-thermal Vaporisation Atomic Absorption Spectrometry	ETV-AAS
Cold Vapour Atomic Absorption Spectrometry	Cold vapour AAS
Atomic Absorption Spectrometry (unspecified)	AAS

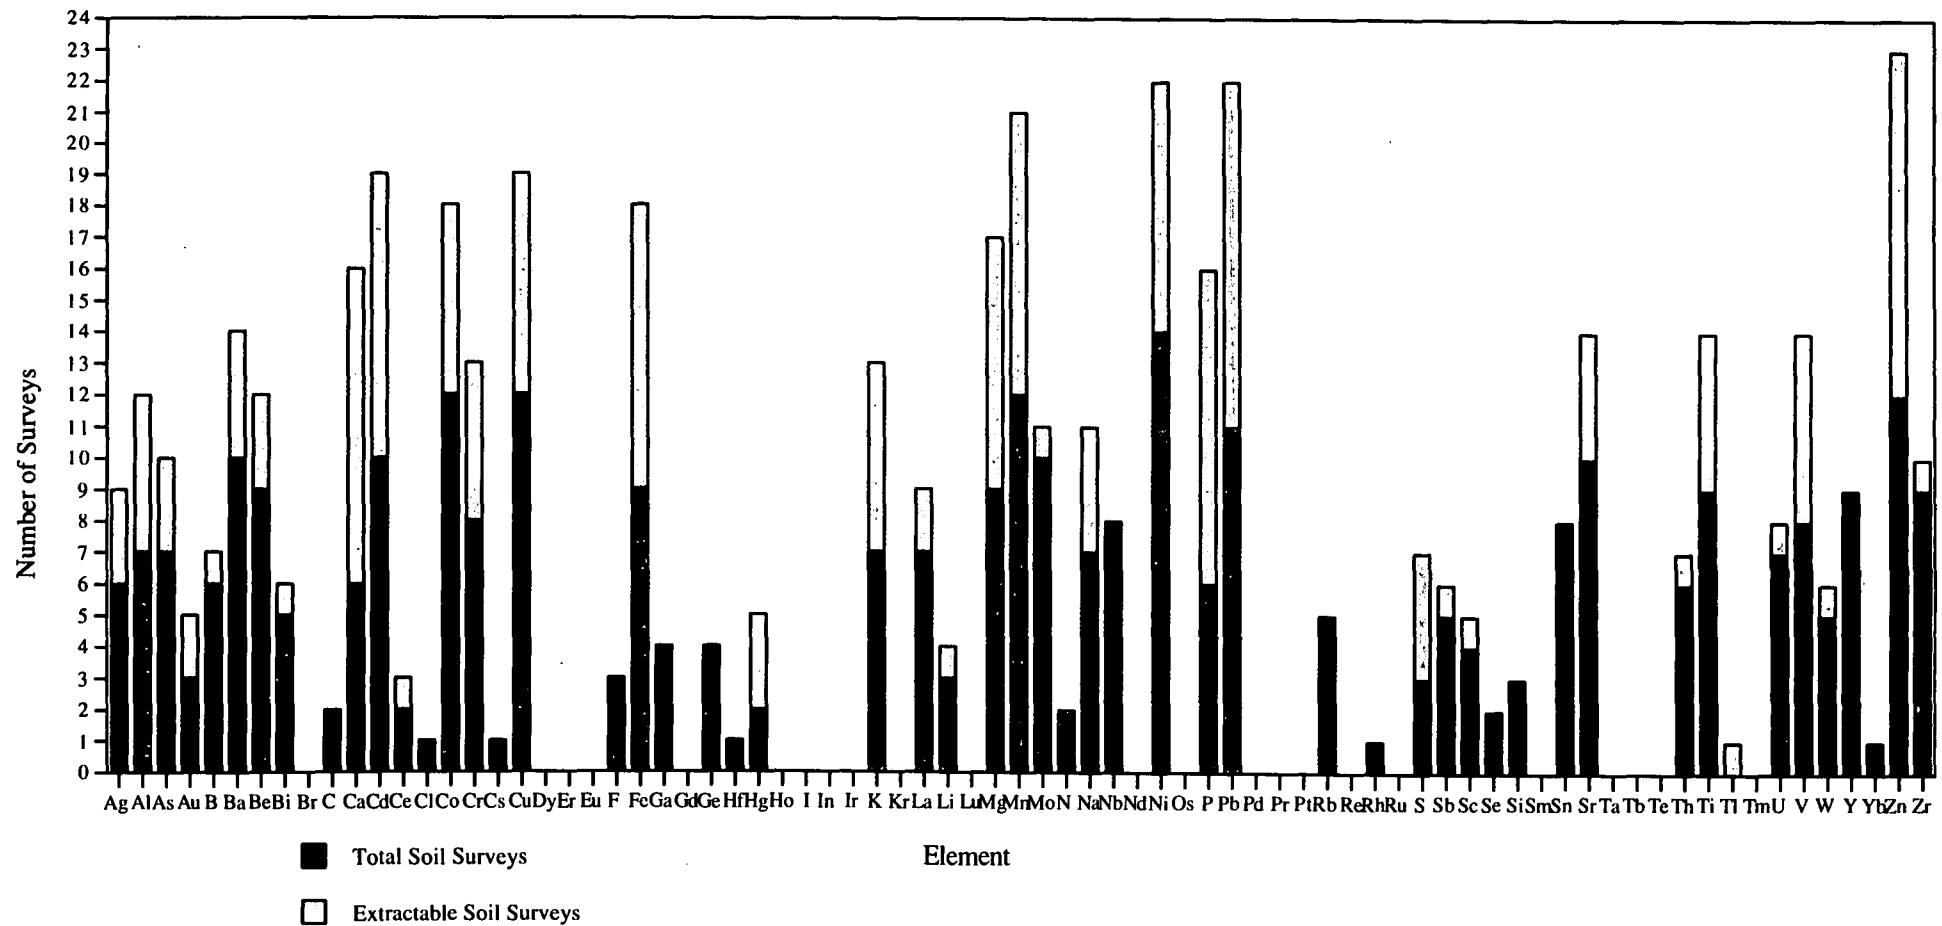

Figure 12 Availability of total and extractable analyses of elements in soils in FOREGS countries.

3.6 Quality Control Procedures

All FOREGS countries employ some form of quality control procedure involving inclusion of field and/ or analytical duplicates in analysis, repeat analysis and analysis of internal and/or international reference materials (Appendix 4 and Table 8). There are, however, no systematic quality control procedures among countries, highlighting the need for the EU-funded laboratory standardisation project proposed at the FOREGS Geochemistry Task Group meeting in January 1995. The UK is the only country where national water standards are included in analysis.

3.7 Archive Sample Material and Digital Data

Most FOREGS countries retain sample archives for stream sediment and soil samples, although Albania is the only country to report storage of surface water samples (Table 9 and Appendix 4). Stream sediment sample archives are available for 14% of the area of FOREGS countries and soil archive material extends to 6% (Figure 13).

Digital data are available for 21% of the FOREGS region for stream sediments, 6% for surface waters and 8% for soils (Figure 13).

4 Conclusions

1. Many FOREGS countries have high-quality multi-element, geochemical data available in digital form at the national level which can be interacted with other geoscience and environmental datasets using GIS.
2. The data have been collected for various purposes including exploration and environmental studies. In several countries multi-purpose surveys are now in progress.
3. This is reflected by the range of sample types collected. Stream sediment, stream water and soil data are available from most surveys. These sample types therefore provide the most appropriate basis for the preparation of environmental geochemical baseline maps of the FOREGS countries.
4. Across the FOREGS countries, stream sediments have been collected using a narrow range of mesh sizes (<150 to <200 µm), close to those recommended in the UNESCO report of IGCP 259.
5. In the case of soil surveys conducted for geochemical purposes, however, the range of mesh sizes is bimodal. Some surveys collect fine mesh sizes (close to those recommended in the UNESCO report of IGCP 259) to integrate with stream sediment data while others follow traditional soil survey methods and use <1000 or <2000 µm fractions.
6. Various analytical methods have been used, partly reflecting the years in which the survey was performed. Most data have been calibrated using international reference materials.
7. Different suites of chemical elements have been determined in different surveys but data for the PHES are generally available.
8. Sample densities range from 1 sample per 0.5 km² to 1 sample per 3500 km².
9. Sample archives are available for re-analysis for up to 14% of the land area of the FOREGS countries.
10. Systematic radiometric data are available for only a small proportion of the land area of the FOREGS countries, despite the Chernobyl accident and increasing concern about natural radioactivity, especially radon gas. This compares very unfavourably with North America, the FSU and many developing countries.

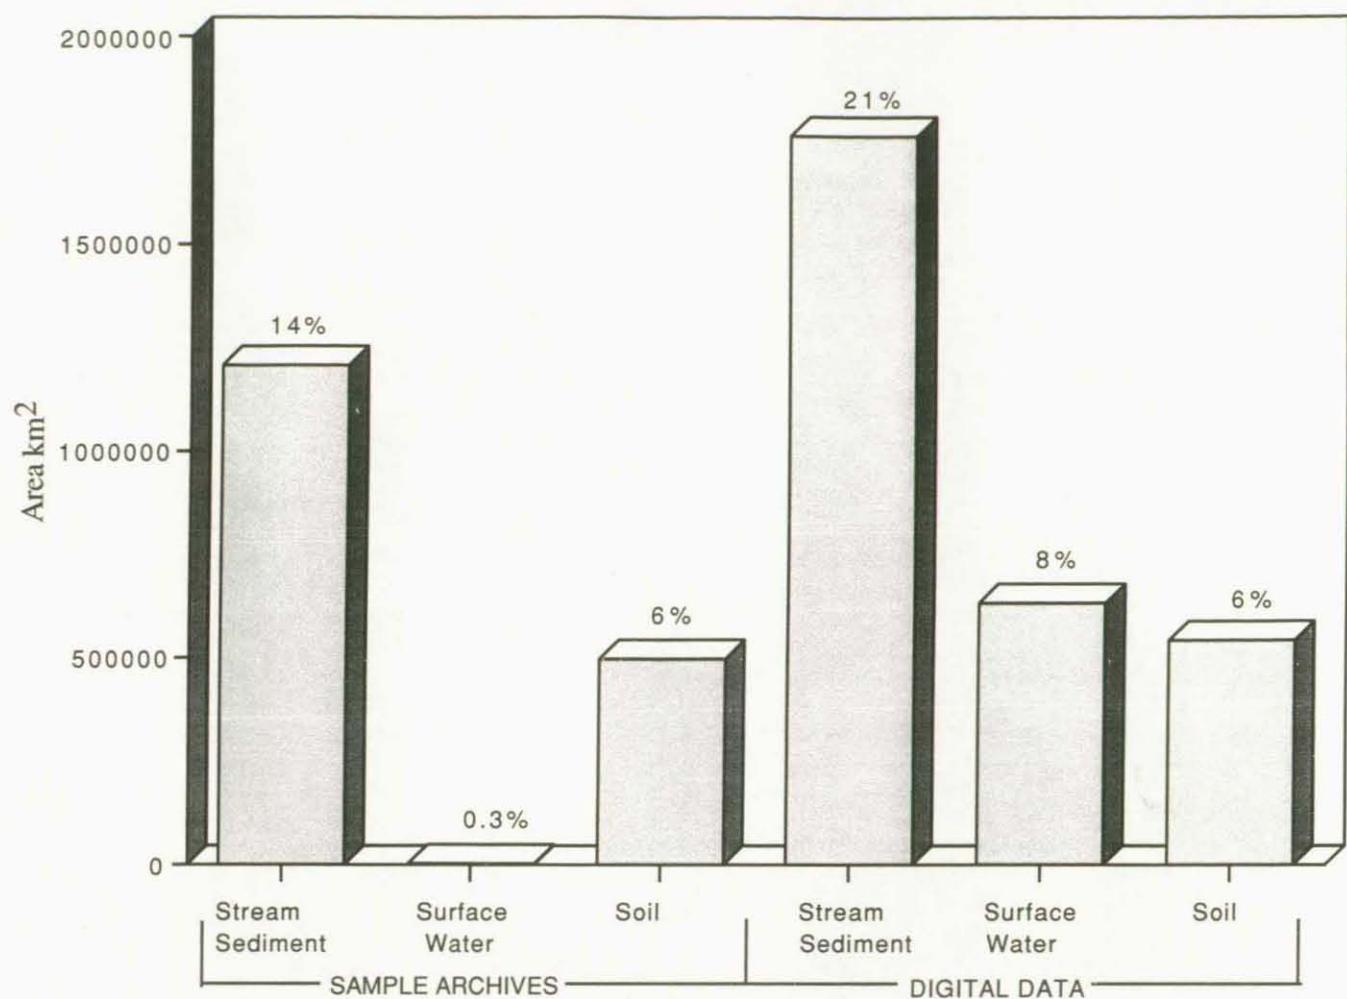

Figure 13 Area of FOREGS countries for which sample archives and digital data are available for stream sediments, surface waters and soils. (Percentage cover of the total areas of FOREGS countries is indicated at the top of each column)

5 Recommendations

1. Modern high-resolution, multi-element geochemical databases prepared to the standards agreed by IGCP 259/360 should be given high priority by FOREGS Directors. These databases have a range of applications comparable to those of other geoscience maps including environmental studies, mineral exploration and geological studies. Such databases are essential if Geological Surveys wish to play the central role in environmental issues concerned with the geochemistry of the surface environment, a subject which is of increasing interest and concern to the public and national governments.
2. The continuing support of FOREGS Directors is requested for:
 - a. The proposal led by GSF to examine the impact of climate change on the mobilisation of PHEs based on available environmental geochemical baseline data (Chemical Time-Bomb Concept)
 - b. Initiatives in organising international conferences such as that of GSSR Baseline Geochemical Mapping in Europe (May 1996) and the BGS-AEG Environmental and Legislative Uses of Geochemical Data for Sustainable Development (March 1996)
3. It is recommended that FOREGS organisations prepare or modify their existing geochemical programmes to ensure that their data conform to IGCP 259/360 standards and are suitable for environmental baseline studies as well as other purposes.
4. In terms of national mapping programmes, it is recommended that FOREGS organisations collect a stream sediment and/or soil and one surface water sample if possible at each sample site, in addition to samples such as till, rock or biological material which they may require for their national purposes. A minimum density of 1 site per 100 km² is recommended (where higher density surveys are available these can be sub-sampled using computer methods).*
- * Standard soil survey methods based on <1000 and <2000 µm size fractions are NOT RECOMMENDED since they involve the preparation and analysis of a large proportion of quartz and other coarse-grained dilutants and are particularly wasteful of effort for developing countries who may wish to follow the European lead.
5. The preparation of European Geochemical Maps should incorporate existing geochemical data. The integration of existing datasets will be greatly aided by collection and analysis of the Global Reference Network (GRN) of samples recommended by IGCP 259.
6. Integration of existing data may require some re-analysis and re-sampling. Additional analysis for environmentally important trace elements such as Se and I is recommended.
7. The collection of the GRN samples is the next priority for FOREGS countries. Samples should be collected according to IGCP 259 recommendations. Stream sediment, surface water, soil, floodplain soil and humus samples are required to maintain global compatibility.
8. Implementation of a GRN of samples in Europe also provides a basis for monitoring changes in environmental geochemical baselines through time. In the UK, for example, it is proposed to combine geochemical monitoring with the operation of the seismic network. The UK is served by 70 seismic monitoring stations and the range of remotely-gathered data from selected monitoring sites will be extended to include surface or atmospheric gamma radiation and radon in soil gas. In addition, it is proposed that routine geochemical sampling of stream sediment, surface water and soil should be carried out during maintenance visits to the seismic network sites. The proposed programme will provide information on both short/medium-term radiometric variation and long-term geochemical change.
9. Analytical methods used for geochemical baselines across Europe urgently require calibration and standardisation among laboratories, and two EU proposals, involving 16 EU countries and 9 non-EU countries led by RGD, have been submitted to the EU Standards Measurement and Testing programme (DG12) and the INCO-Copernicus Programme (DG12). The continuing support of the FOREGS Directors is sought for these proposals and for the collection by each national survey of the Global Reference Network samples that they will require.
10. It is recommended that FOREGS should produce a newsletter detailing the activities of all FOREGS groups and any proposals submitted to the EU. This would raise the profile of proposals ensuring that all FOREGS countries wishing to collaborate are aware of potential projects.
11. The FOREGS Directors' support is sought for the preparation of an exhibit for presentation at environmental and geochemistry meetings run by learned societies and trade and professional associations.
12. FOREGS Directors are requested to press the case, especially with the EU and the EEA, for additional funding for baseline geochemical and radiometric surveys across Europe.
13. Following this final report of the task group (1996) consideration should be given to establishing a standing group involving all FOREGS countries to oversee the preparation of a geochemical database for Europe to IGCP 360 standards with the chairmanship rotating once every two years. The standing group should also act as the European Regional Committee for the IUGS Working Group on Continental Geochemical Baselines.

Appendix 1 Example of the Inventory Questionnaire Form

Forum of European Geological Surveys (FOREGS) Geochemistry Task Group 1995
Inventory of Regional Geochemical Data in FOREGS Countries

Name of person to whom form has been sent: _____

Position: _____

Name of survey organisation: _____

Address: _____

Name of person completing form: (if different from above) _____

Position: _____

Name of survey organisation: _____

Address: _____

Other Survey Organisations:

Please list below the names and addresses of any other national organisations responsible for collection of regional geochemical data e.g. Soil Survey Institute.

A. DRAINAGE SEDIMENT SURVEYS

A1. General Information

Organisation responsible _____

Year(s) of collection _____

Contact person responsible (name) _____

Survey complete Ongoing survey

A2. Objective of Survey

Exploration *Environment* *Multipurpose*

Other _____
(please specify)

A3. Locational Information (please also show on accompanying map)

Country _____

Survey Area Name _____

*Minimum and maximum UTM co-ordinates
of survey area boundaries and UTM zone* _____

*Approximate
area in km²*

(minimum area 5000 km², except in Cyprus
Luxembourg, Liechtenstein, Monaco)

Number of samples _____

Approximate sample density _____
(samples per km²)

Comments:

A4. Sample Information

Sample type

'Active' Active Other
Bank channel (please specify) _____

Typical catchment area of stream (km²) _____

Typical stream order _____

Type of material Clastic Particulate Organic
Other (please specify) _____

Bulk sample weight before sieving (kg) _____

Sample weight after sieving (g) _____

Depth in sediment (cm) _____

Field treatment Wet sieving Mesh size _____
(in microns)
Other (please specify) _____

Composite sample Length of stream section (m) _____

Number of individual samples forming composite _____

Please specify method of homogenising samples in the field

Field duplicate samples collected Percentage of samples _____
(e.g. 1 duplicate per 100 samples = 1%)

A5. Sample Preparation

Drying Freeze drying Deep freezing Oven drying Air drying

Other

(please specify) _____

Maximum temperature during drying (°C) _____

Ashing Wet Dry

Sieving Wet Dry

Sieve type: Brass Stainless steel Nylon

Other

(please specify) _____

Maximum mesh size (in microns) _____

Minimum mesh size (in microns) _____

Sample weight after sieving (g) _____

Disaggregation procedures

Agate pestle
and mortar

Ceramic pestle
and mortar

Other _____
(please specify)

Separation procedures

Magnetic separation
Density separation

Heavy liquids
Jigging

Other _____
(please specify)

Grinding

Agate

Cr steel

Tungsten carbide

Ceramic

Mn steel

Other

(please specify) _____

Final mesh size (in microns) _____

Homogenisation

(please specify composites)

Subsampling procedures

Cone & quarter Random grab Other _____
(please specify)

Riffle

Rotary

A6. Chemical Analysis (use attached list of techniques only)***Analytical information***

Element	Total	Extractable	Solution and Molar Strength State whether hot or cold	Size (g) of Subsample	Pre-concentration Method	Analytical Method

Appendix 2 Organisations included in the FOREGS geochemical inventory

Geophysical and Geochemical Centre of Tirana (GGCT)	Albania
Geologische Bundesanstalt (GB)	Austria
Geological Survey of Belgium (GSB)	Belgium
University of Louvain-La-Neuve (UCL)	
University of Leuven (UL)	
Forest Soil Co-ordinating Centre (FSCC)	
Polytechnic Facility of Mors (PFM)	
Institut za Geoloska Istrazivanja (IGI)	Croatia
Geological Survey Department (GS Dept)	Cyprus
Czech Geological Survey (CGS)	Czech Republic
Ministry of Agriculture (Soil Survey)	
Geomineral Coop (Geomin)	
Geofyzika A S (Geofyzika)	
Danmarks Geologiske Undersøgelse (GDU)	Denmark
Ministry of Agriculture and Fisheries (MAF)	
Department of Plant and Soil Science (DPSS)	
Eesti Geoloogakeskus (EG)	Estonia
Geological Survey of Finland (GSF)	Finland
Bureau de Recherches Géologiques et Minières (BRGM)	France
Geologisches Landesamt North-Rhine-Westphalia (GLNRW)	Germany
Bundesanstalt für Geowissenschaften und Rohstoffe (BGR)	
Institute of Geology and Mineral Exploration (IGME)	Greece
Grønlands Geologiske Undersøgelse (GGU)	Greenland
Geological Institute of Hungary (GIH)	Hungary
Orkustofnun (Ork)	Iceland
Geological Survey of Ireland (GSI)	Irish Republic
Ministry of Industry (MCA)	Italy
University di Napoli (Uni di Napoli)	
Geological Survey of Latvia (GSL)	Latvia
Lietuvos Geologijos Taryba (LGT)	Lithuania
Institute of Geology (IG)	
Institute of Forestry (Forest Inst)	
Service Géologique du Luxembourg (See Belgium)	Luxembourg
Rijks Geologische Dienst (RGD)	The Netherlands
Norges Geologiske Undersøkelse (NGU)	Norway
Panstwowy Institut Geologiczny (PIG)	Poland
Aveiro University (Aveiro Uni)	Portugal
Instituto Geológico e Mineiro (IGM)	
Geological Institute of Romania (GIR)	Romania
Geological Survey of the Slovak Republic (GSSR)	Slovakia
Soil Survey of Slovakia (Soil Survey)	
Forestry Research Institute (Forest Res Inst)	
Uranpress (Uranpress)	
Institute for Geology, Geotechnics and Geophysics (GZL)	Slovenia
Instituto Tecnológico GeoMinero de España (ITGE)	Spain
Empresa Nacional del Urano SA (ENUSA)	
Sveriges Geologiska Undersökning (SGU)	Sweden
Department of Mineral Resources (NSG)	
Schweizer Landeshydrologie und Geologie (SLG)	Switzerland
Maden Tektik ve Arama (MTA)	Turkey
Inst. of Geochemistry, Mineralogy and Ore Formation (IGMOF)	Ukraine
British Geological Survey (BGS)	UK
Soil Survey of England and Wales (Soil Survey)	
Environmental Geochemistry Research Group, (EGRC,ICL)	
Imperial College London	
Macaulay Land Use Research Institute (MLURI)	

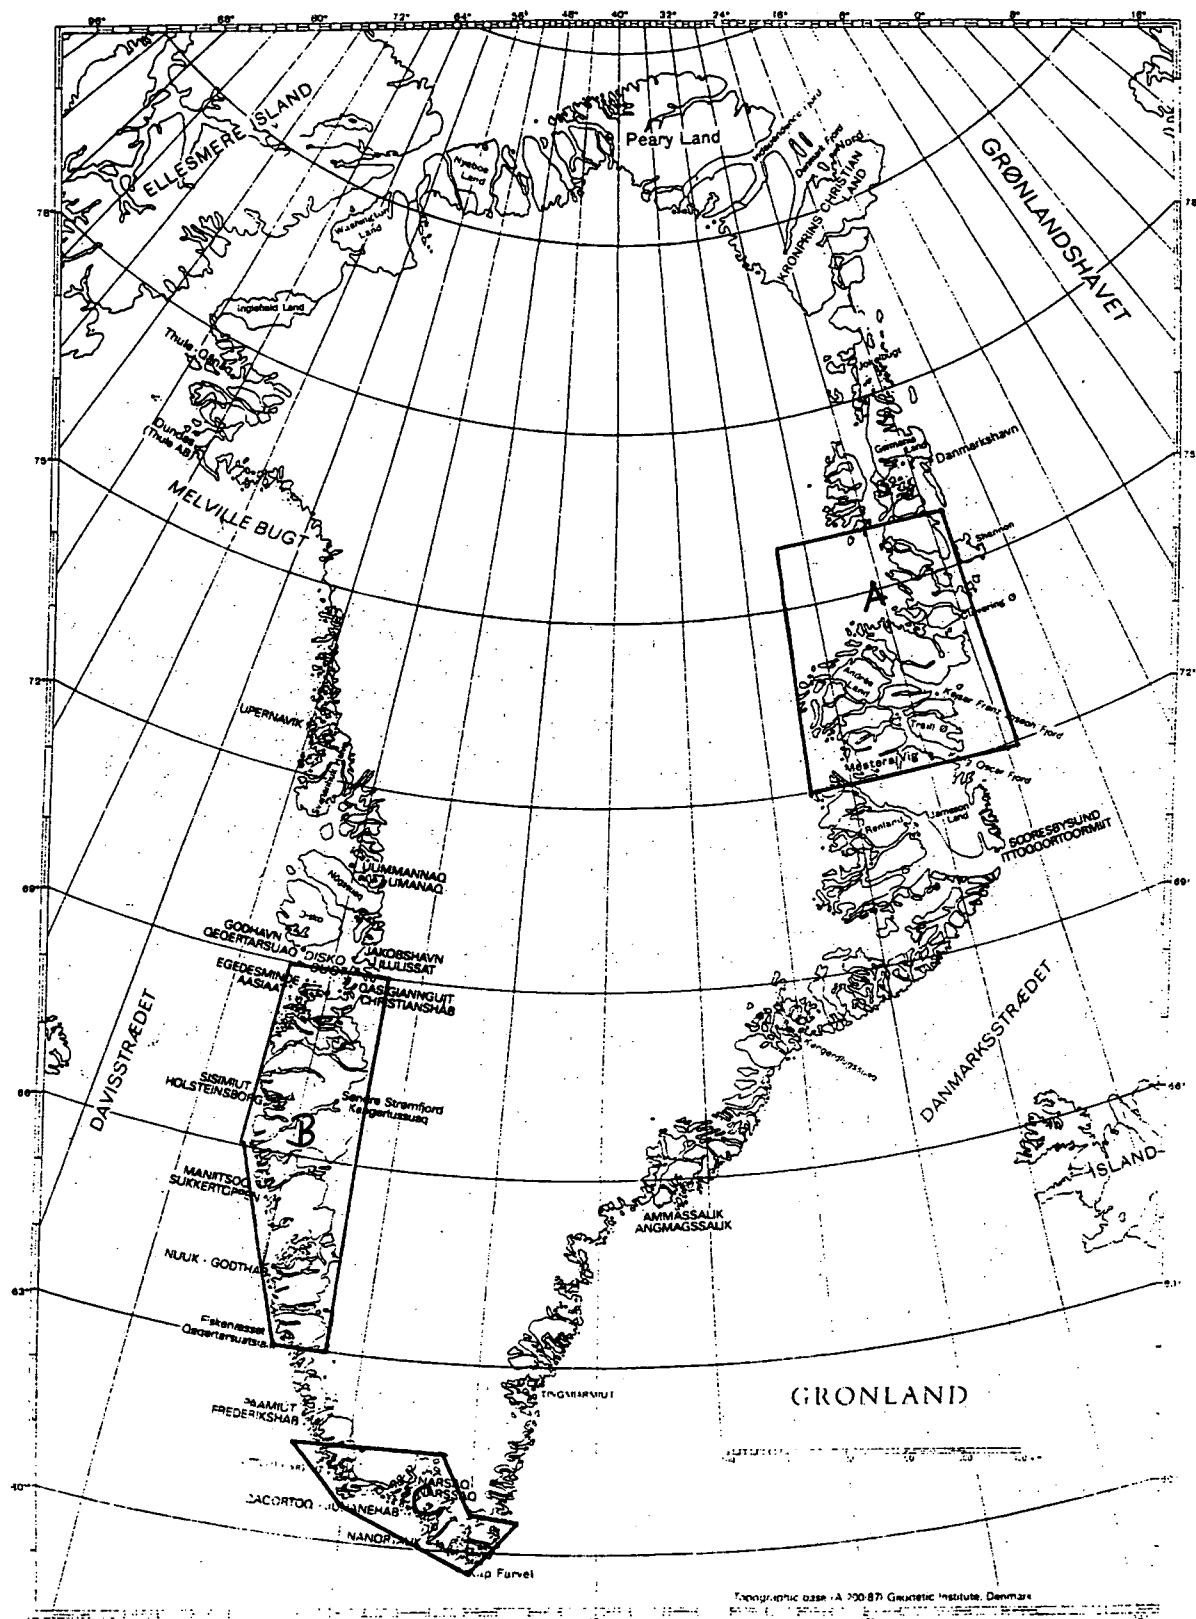

Appendix 3 Regional Geochemical Surveys in Greenland

Geochemical stream sediment and stream water surveys: A-G
 Radiometric ground-scintillometry surveys: B, C, E, F, G

Source: Geol. Surv. of Canada, 1987, Geological Institute Denmark

Air-borne gamma-spectrometry surveys

Appendix 4 Summary table of information in the inventory database

Organisation	Country	Survey Type	Country Size km ²	Years of Collection	Survey Status	Object of Survey
GGCT(1)	Albania	Stream sediment	28000	1993–1996	Ongoing	Multi-purpose
GGCT(2)	Albania	Soil	28000	1993–1996	Ongoing	Multi-purpose
GGCT(3)	Albania	Stream/spring water	28000	1993–1996	Ongoing	Multi-purpose
GGCT(4)	Albania	Radiometric	28000	1993–1996	Ongoing	Multi-purpose
