Days Suitable for Fieldwork in Missouri

he number of days available to complete land-based agricultural activities influences decisions about inputs, such as variety/hybrid planted and pesticide used, and machinery. The limited fieldwork days available for completing crucial tasks — such as tillage, planting and harvest — require careful management.

A large machinery complement will complete fieldwork quickly but can increase ownership costs. A small machinery complement may have lower ownership costs but may also delay some key activities that affect productivity. The size of machinery needed to efficiently complete the necessary activities depends on how many days the machinery can actually be used in the field.

The Missouri Agricultural Statistics Service (MASS) reports the number of days each week that soil and moisture conditions are suitable for fieldwork. These data start around the first week of April. This start date leaves a gap in fieldwork days data when important field operations such as fertilizer application and early corn planting occur.

Average number of days suitable for fieldwork

Figure 1 shows the distribution of fieldwork days for the 61-calendar-day periods of April–May and September– October. Use the graph by selecting the number of days that you would like to have available for fieldwork. Draw a straight line up. When your line intersects either the April–May or September–October plots, draw a straight line left to the axis labeled "Probability." The result is the percentage of time that you could expect the desired number of fieldwork days to be available. For example, 35 fieldwork days or more occur about 30 percent of the time during the April–May period. That means that 70 percent of the time you will *not* have the 35 fieldwork days you want.

Table 1 summarizes the average number of weekly fieldwork days from 1977 to 2015 in each of the nine MASS reporting districts. The actual number of suitable fieldwork days varies considerably from year to year. Estimates are for seven-day workweeks. If fieldwork will not be done every day of the week, adjust the data by multiplying by the fraction of the week that will be worked, such as % or 0.857

Figure 1. Probability of weather favoring completion of fieldwork in Missouri within a specified number of days during an April–May period and a September–October period.

for a six-day workweek. Figure 2 shows the weekly averages for each district with a trend line to smooth out the weekly variability.

Calculating machinery needs

After you have found the average number of days that you can expect to be able to perform fieldwork, the minimum necessary daily machinery capacity can be computed. The formulas for this computation are

acres worked per day = acres ÷ days suitable for fieldwork

acres worked per hour = acres per day ÷ working hours per day

For example, in southeast Missouri between April 3 and April 17, you can expect 6.1 days (3.0 + 3.1 days, from Table 1) suitable for fieldwork during that two-week period. If you have 1,000 acres of corn to plant, you need to be able to plant 164 acres per day $(1,000 \div 6.1)$ to finish within two weeks under average circumstances. If the planter can be operated 14 hours per day, a planter large enough to plant 11.7 acres an hour (164 acres \div 14 hours) is needed.

Because these data are annual averages, the above example implicitly assumes a completion rate of about 50 percent. This means that in about half the years, less than 1,000 acres will be planted in the two-week period when planting at 11.7 acres an hour. This level of risk may not be acceptable to all operators.

Service reporting districts.

Online tools for farmers

Several online tools using the days-suitable-for-fieldwork data are available to help farmers make informed decisions.

A spreadsheet calculator called Probable Fieldwork Days Model can be downloaded from the Spreadsheet Tools section of the University of Missouri Food and Agricultural Policy Research Institute (FAPRI) website at *bttp://* fapri.missouri.edu/farmers-corner. This calculator — and its accompanying guide, MU Extension publication G363, Fieldwork Days and Machinery Capacity - helps farmers refine machinery size decisions and evaluate the chance of inadequate time to complete fieldwork. The calculator computes the probability that work can be completed for specific cropping activities during defined time periods in any region of the state. Users can quantify how a change in machinery size or crop acreage affects the risk of not completing the work.

An online interactive tool called Corn Split Nitrogen Application is accessible from the Decision Support Tools section of the Useful to Usable (U2U) project's website at *https://mygeohub.org/groups/ u2u/tools*. This tool combines the fieldwork days data with a corn growth model and weather information to estimate the probability of successfully implementing a post-planting nitrogen application for corn production.
