Brief 70-10712

NASA TECH BRIEF

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the National Technical Information Service, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Division, NASA, Code UT, Washington, D.C. 20546.

A New Method for Measuring Slipperiness of Airport Runways and Other Paved Surfaces

The problem:

With the advent of larger and faster jets in commercial and military aviation, a method of accurately predicting aircraft stopping distances on wet runways is necessary and desirable in preventing major disasters and improving safety.

The solution:

Aircraft stopping distances on wet runways can be accurately predicted by measurements taken with a conventional automobile equipped with a diagonal braking system and simple instrumentation for recording stopping distances.

How it's done:

The test automobile is driven down the runway at a speed of 60 miles per hour. The stopping distance of the automobile, using the diagonal braking system, is measured for locked wheel skids under both wet and

dry runway conditions. The ratio of measured wet-to-dry stopping distances shows good correlation to the wet-to-dry stopping distance ratios experienced by several representative aircraft during extensive comparative testing on a wide variety of runway surfaces and surface conditions.

Note:
