

NASA TECH BRIEF

NASA Pasadena Office

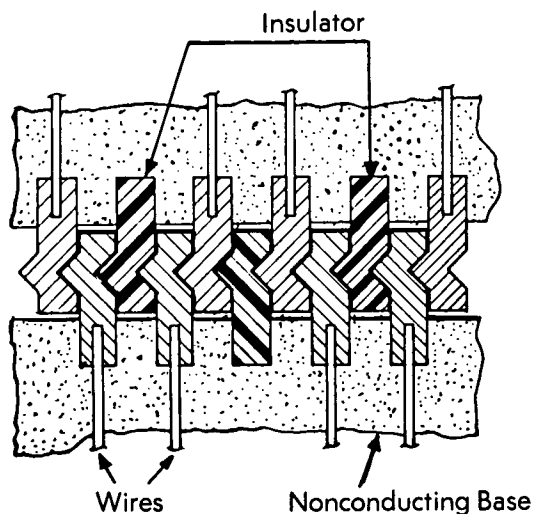

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the National Technical Information Service, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Office, NASA, Code KT, Washington, D.C. 20546.

Zipper-Type Electrical Connectors

The problem:

Multipin electrical connectors are quite bulky, and because they are made of small, precision parts, reliability of firm connection is not high. Moreover, since adequate pin-to-socket friction must be provided for

proper electrical contact and all pins must release simultaneously, a great deal of force must be applied to separate a connector plug from its socket. Accordingly, it was considered desirable to seek a design for a simple, reliable connector which can be separated by application of small forces.

The solution:

An electrical connector of a zipper-like configuration, in which sequentially interlocking tines serve as electrical contacts or insulators.

How it's done:

An ordinary zipper with metal tines can be converted readily to an electrical connector by replacing every third metal tine in each row with a nonconducting tine. As indicated in the diagram, wires are attached to both rows of metal tines; when the zipper is closed, the metal tines are meshed together and electrical circuits are completed. The force required to make or break a connection is relatively low because tines are sequentially locked or released as in a zipper; moreover, selected circuits can be energized or interrupted in a desired sequence.

Many types of zippers can be used to form connectors; it is of interest to note that existing zipper-forming machines can be modified readily to produce connectors of nearly any length.

Patent status:

NASA has decided not to apply for a patent.
