

NASA TECH BRIEF

John F. Kennedy Space Center

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the National Technical Information Service, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Office, NASA, Code KT, Washington, D.C. 20546.

Transfer of Gaseous Oxygen From High-Pressure Containers and the Joule-Thomson Inversion

The Joule-Thomson inversion associated with the transfer of gaseous oxygen from high-pressure containers has not been explored beyond pressure of 5000 psig ($34.4 \times 10^6 \text{ N/m}^2$). As a result, a study was performed to determine this point in the 3000- to 10,000-psig (20.6×10^6 - to $68.9 \times 10^6 \text{ N/m}^2$) pressure range at flow rates ranging from 24.5 to 1300 standard cubic feet per minute (0.7 to $36.8 \text{ m}^3/\text{min}$). The transfer process in this study was assumed to be a constant enthalpy throttling process.

Normally, when gases are throttled at high pressures, there is a drop in temperature in the downstream gas. This occurs when Joule-Thomson coefficient μ is positive. However, at sufficiently-high upstream pressures, the coefficient can become negative and the gas will heat up. The pressure and temperature at which μ changes signs is the Joule-Thomson inversion point.

From the experiments performed in the study, it was determined that oxygen transferred at ambient temperature and pressures up to 10,000 psig ($68.9 \times 10^6 \text{ N/m}^2$) consistently dropped in temperature. All results therefore

indicate that gaseous oxygen transferred at ambient temperature does not exhibit the Joule-Thomson inversion below 10,000 psig.
