NASA TECH BRIEF

Langley Research Center

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the National Technical Information Service, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Office, NASA, Code KT, Washington, D.C. 20546.

Horn Antenna With V-Shaped Corrugated Surface

The corrugated horn antenna characteristics are low side and back lobes, a rotationally symmetric radiation pattern, and broadband performance. These properties are particularly useful in low noise applications such as feed horns for reflectors and radiometer antennas. The usual corrugation is rectangular in shape. A new corrugation shape (see illustration) is more easily machined for millimeter wave application and is better suited for folding antenna design. A parametric study, using an integral equation solution, is available for both the rectangular and new V-shaped corrugations.

The study involved looking into the influence of corrugation density and shape on the power loss, surface current, and scattering from a ground-plane corrugated surface junction. It shows that for operation as a cutoff corrugated surface the "V" corrugation depth should lie between 0.3125\(\lambda\) and 0.625λ (λ = wavelength). For the rectangular corrugations the corresponding depth range is 0.25\(\lambda\) to 0.5 λ . The radiation patterns for both corrugations are nearly independent of the corrugation density (corrugations per wavelength), and the direction of maximum intensity decreases with increasing corrugation depth.

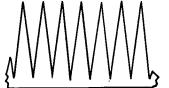

The "V" corrugations have a higher relative power loss. For example, at the minimum corrugation depth-to-wavelength ratio, $d/\lambda = 0.25$ (rectangular) and $d/\lambda = 0.3125$ ("V"), the "V" corrugation loss is approximately 6.5 dB larger. If low loss is important, the first few "V" corrugations should be polished or silver plated. For a foldable antenna the first part may be rigid and rectangular corrugations may be used to obtain lower loss, while the remainder would be the folding "V" corrugations. In any event, the loss in a corrugated horn would be equal to or less than the loss in a conducting wall made of the same material and having the same shape and surface finish.

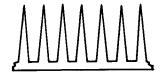

A "V" corrugation horn has been built, and its performance has been compared with a rectangular corrugation horn of the same shape. Both horns were designed for C-band operation (3.95 to 5.85 GHz). The E-plane contained the corrugations and was flared at 36.1°. The H-plane was flared at 33.12°, and it had a slant length of 42.19 cm (16.609 in.) with a 4.75-cm (1.872-in.) waveguide feed. Measured performance showed that the new "V" corrugations and rectangular corrugations have nearly the same pattern beamwidth, gain, and impedance.
