Abstract

Large potential differences between parts of the spacecrafts or between the spacecraft and the plasma will cause instruments to give misleading or meaningless data. Potentials and currents at various locations on the Pioneer Venus Orbiter are predicted by constructing an electrical model of the spacecraft and the environment, and calculating the response of the electrical model to the environment model.

Five environment models were constructed to represent the solar wind and the upper, middle, and lower ionosphere of Venus. The spacecraft structure was modeled with over 140 passive electrical elements representing structural elements of the spacecraft. Electron, ion, secondary electron, and photocurrents to the spacecraft from the plasma were calculated, ignoring sheath effects.

In all but one case, potentials of interest were less than 1 volt. Potential differences between widely separated points on the equipment shelf were less than 1 mV. The one area of concern is the solar panel potential when the orbiter is passing through the bowshock region. Here we assumed a high photocurrent and a low density, low temperature plasma, with solar panel potentials approaching 5 volts positive. Some experimenters indicated this would present a problem in interpreting results. Further study is needed to clarify this issue; otherwise, spacecraft potentials are well within design levels.

Work performed by Hughes for Ames Research Center under Contract NAS 28300.

1. INTRODUCTION

Spacecraft for two Pioneer Venus missions are being built by Hughes Aircraft Company for NASA Ames Research Center. In the multiprobe mission, a large entry probe will make detailed measurements of the Venusian atmosphere and clouds. Three small probes will simultaneously sample conditions at widely separated points. The probe bus will make upper atmospheric measurements prior to its entry and burnup. In the orbiter mission, a spacecraft will circle the planet for a Venusian year (225 days), examining long term and global effects. The orbiter will be placed in a highly inclined elliptical orbit with a low altitude, midlatitude periapsis location. Most of the measurements will be taken during the periapsis pass.

Figure 1 shows the Pioneer Venus Orbiter. There is a conducting mesh over the forward end of the spacecraft to ensure a uniform charge distribution. Table 1 lists the instruments on the orbiter that are concerned with the charge state of the spacecraft. None of the experimenters felt their instrument would influence the charge state of the spacecraft.

Figure 1. Pioneer Venus Orbiter

Table 1. Experiments Concerned with Charge State of Spacecraft

Instrument	Operating Altitude	Important Features
Ion. mass spectrometer Dr. Harry Taylor	<5000 km	No external potentials; current $\geq 5 \times 10^{-14}$ A. 2 in. dia aperture; would prefer negatively charged spacecraft
Electron temperature probe Dr. Larry Brace	≥ 6000 km	Exposed potentials vary from -5 to +7 V; total area ~ 13 cm ² ; single probe area = 4 cm ²
Retarding potential analyzer Dr. William Knudsen	All	Exposed potential +6 V current to instrument could be as high as 10^{-4} A; aperture diameter = 8 cm; would prefer spacecraft potential from -1 to -5 V.
Plasma analyzer Dr. John Wolfe	All	Potential ± 700 V; maximum current 10^{-12} A; aperture area = 1 cm ²
Electric field detector Dr. Fred Scarf	All	No exposed potentials; measures potential difference across instrument at frequencies above 100 Hz

2. CHARGED-PARTICLE ENVIRONMENT

The charged particle environment for the Pioneer Venus Orbiter mission is an upper bound on empirical information obtained from various sources.¹⁻⁴ The model covers the full range of altitudes where scientific packages on the orbiter vehicle are operational. The model is summarized in Table 2.

Table 2. Pioneer Venus Orbiter - Charged Particle Environment

Region Label	Environment Component	Altitude Range, km	Charged Particles	Maximum Density, per cm ³	Energy Levels, eV
I	Solar wind	∞ to 1000	Protons electrons	10 10	10 to 100 10 to 100
II	Upper ionosphere	1000 to 700	Ions (CO ₂ ⁺) electrons	10 ² 10 ²	<0.1 <0.1
III	Middle ionosphere	700 to 350	Ions (CO ₂ ⁺) electrons	10 ³ 10 ³	<0.1 <0.1
IV	Lower ionosphere 1	350 to 200	Ions (CO ₂ ⁺) electrons	5×10^4 5×10^4	<0.1 <0.1
V	Lower ionosphere 2	200 to 150	Ions (CO ₂ ⁺) electrons	5×10^5 5×10^5	~ 0.06 ~ 0.06

A cosmic ray background⁵ will be present at all altitudes. Since the current densities are low and the particle energies high, there will be negligible contribution to a surface charge or potential buildup on the orbiter exterior surfaces from this source. The solar wind component of the environment dominates down to an altitude of approximately 1000 km, the bowshock region (actual altitude strongly dependent on vehicle trajectory). The ionosphere begins to develop at lower altitudes and particle and current densities peak at an altitude in the range of 150 to 200 km (~ 500°K thermosphere).

The ionosphere is extremely dynamic and the altitudes bounding the regions of interest should not be taken as rigid divisions. In addition, the solar radiation (~ 5750°K blackbody, 2.7×10^{-4} ergs/cm² sec) at Venus contributes strongly to the spacecraft charge for the orbiter because of the effect of photoemission from the spacecraft external surfaces.

Electron and ion currents, photoemission currents, and secondary electron currents are included as appropriate. Tables 3 and 4 list current density (amperes per square centimeter) used in calculations for each region. These current densities are one-half the expected maximum thermal currents. The secondary electron current is dependent on a parameter E_{max} , the energy at maximum secondary electron emission. Table 4 lists the secondary electron emission for two typical E_{max} and $S_{max} = 1$. S_{max} is the number of secondary electrons emitted at E_{max} . The resistivity of the plasma is calculated from kinetic theory.⁶ In calculating the resistance to the plasma from each element, the Debye length⁶ was used as the length through the plasma. Table 5 lists the terms included in a power series expansion of current versus potential.

KEY FOR TABLES 3 THROUGH 5

ALT	= altitude range	ν	= collision frequency
N_e	= electron density, electron/cm ³	J_e	= electron current density
kT_e	= electron temperature, eV	J_i	= ion current density
λ_D	= $\left(\frac{kT}{4\pi N_e e^2}\right)^{1/2}$ = Debye length, cm	J_e/e	= secondary electron current density
η	= $\frac{m_e c^2 \nu}{N_e e^2}$ = kinetic theory resistivity;	J_{hu}	= photoemission current density
		J	= total current density

Table 3. Plasma Parameters

Region	Altitude, km	N_{e0} , cm^{-3}	kT_e , eV	λ_D , cm	η , ohm-cm
I Solar wind	∞ to 1000	10	100	2.35×10^3	3.194×10^3
II	1000 to 700	100	0.1	23.5	2.8×10^8
III	700 to 350	10^3	0.1	7.43	2.5×10^7
IV	350 to 200	5×10^4	0.1	1.05	6.0×10^5

Table 5. Power Series Expansion of Total Current Density in One Dimension

$$\begin{aligned}
 J_e &= \frac{n_0 e^2}{2} \left(\frac{-2kT}{\pi m c^2} \right)^{1/2} e^{-e\phi/kT} = J_{e0} e^{-e\phi/kT} \\
 J_i &= \frac{1}{40} J_e e^{e\phi/kT} = J_{i0} e^{e\phi/kT} \\
 J_{e/e0} &= J_{e0} (7.4) \frac{S_{\max}}{E_{\max}} \left\{ 1 - e^{kT/E_{\max}} \left(\frac{\pi kT}{E_{\max}} \right)^{1/2} \left[1 - \text{erf} \left(\left(\frac{kT}{E_{\max}} \right)^{1/2} \right) \right] \right\} \\
 J_{e/e} &= J_{e/e0} e^{+2e\phi/kT} \\
 J &= J_{hu} + J_i + J_{e/e} \cdot J_e \\
 J &= (J_{hu} + J_{i0} + J_{e/e0} \cdot J_{e0}) + (J_{i0} + 2 J_{e/e0} + J_{e0}) \left(\frac{e\phi}{kT} \right) \\
 &\quad + (J_{i0} + 4 J_{e/e0} \cdot J_{e0}) \frac{1}{2} \left(\frac{e\phi}{kT} \right)^2 + (J_{i0} + 8 J_{e/e0} \cdot J_{e0}) \frac{1}{6} \left(\frac{e\phi}{kT} \right)^3 \\
 &\quad + (J_{i0} + 16 J_{e/e0} \cdot J_{e0}) \frac{1}{24} \left(\frac{e\phi}{kT} \right)^4 + \dots
 \end{aligned}$$

*One-half maximum values.

In addition to the thermal current, the spacecraft will see a current due to the relative velocity of the spacecraft and the plasma. This is called a ram current. Typical ram currents are shown in Table 6. Both the electron and ion currents will be increased by the ram current on surfaces facing into the velocity vector. Both currents will be reduced on surfaces hidden from the velocity vector. Table 7 compares ram and thermal currents for the Pioneer Venus Orbiter. In Region I, the relative velocity is that of the solar wind. In Regions II through V, the relative velocity is the velocity of the spacecraft in its orbit. In Regions I and II, the photocurrent dominates and ram currents will have little effect on the net spacecraft charge. In Regions III, IV and V, the ram current will tend to make the spacecraft potentials more positive.

Table 6. Ram Currents

Region, km	$\langle V \rangle$, km/sec	N , per cm^3	J , A/cm^2
>1000	500.00	10	8×10^{-11}
1000	9.16	100	1.5×10^{-11}
700	9.38	1000	1.5×10^{-10}
350	9.66	5×10^4	7.7×10^{-9}
200	9.78	5×10^5	7.8×10^{-8}

Table 7. Likely Effect of Ram Currents

Region, km	Thermal			Comment
	J_{rain}	$J_{e\text{max}}$	$J_{i\text{max}}$	
>1000	8×10^{-11}	3×10^{-10}	6×10^{-12}	Photocurrent dominates; ram current will make no difference to charge state of spacecraft; may influence experiments. Greatly increases $J_{i\text{g}}$; no effect when phase near zero; will tend to make spacecraft voltage more positive.
1000	1.5×10^{-11}	8×10^{-11}	2×10^{-12}	
700	1.5×10^{-10}	8×10^{-10}	2×10^{-11}	
350	7.7×10^{-9}	4×10^{-8}	1×10^{-9}	
200	7.8×10^{-8}	3×10^{-7}	8×10^{-9}	

3. SPACECRAFT ELECTRICAL MODEL

The electrical model for the orbiter includes more than 140 electrical elements and over 70 nodes, each representing an important spacecraft location (see Figure 2). This electrical model was constructed as described in⁷ and the following discussion outlines the formulation of the models.

3.1 Thrust Cone (Series 10)

The magnesium thrust cone was modeled as a series of linear inductors and resistors. A central node was used to provide a location for a capacitance to the surrounding solar panel substrate. The lower end of the cone was tied directly to the equipment shelf support struts and the upper end represented the interface with the BAPTA and equipment shelf.

3.2 Equipment Shelf Support Struts (Series 20)

The 12 support struts were reduced to an equivalent configuration of four to fit the simplified quadrant model of the equipment shelves and surrounding solar panels and substrate. The four strut elements were then modeled as linear inductors and resistors. Estimated resistances of bonded joints were included where it was felt important.

3.3 Equipment Shelf (Series 30)

The equipment shelf was modeled in quadrants with circumferential and radial inductances and resistances calculated for each. A capacitance to the forward aluminum mesh and thermal blanket was also included. (Where two capacitances appear in series with an unimportant intervening node and one is much larger in magnitude than the other, the larger capacitance is omitted from the model for simplification, or an equivalent calculated.)

3.4 BAPTA and BAPTA Support Cone (Series 40)

The BAPTA and its support structure were modeled as an inductor and resistor tied at the ends to the equipment shelf and the main antenna supports.

3.5 Main Antenna Support, Dish, and Forward Omni (Series 50)

The aluminum antenna support structures were modeled as linear inductors and resistors with a node at the main dish and at the omni. Capacitances were calculated for the dish and the omni to infinity. An estimate of mutual inductance coupling with the antenna feed structure was also included.

		73	ANTENNA FEED TOP
		74	AFT FACING SIDE

3.6 Antenna Feed Strut and Cap (Series 60)

The antenna feed structures were modeled as an inductor and resistor with a node at the feed. The capacitances to the feed cap and to infinity were included.

3.7 Solar Array and Substrate (Series 70)

The solar panel enclosure was modeled as an oblate spheroid in order to calculate a representative capacitance to infinity. It was then divided into quadrants and longitudinal and circumferential inductances calculated from the formulas for a lossless transmission line. Associated resistances were also apportioned. Capacitances were calculated between important elements within the solar array and to the thrust cone.

3.8 Substrate Extension and Mesh Wrap (Series 80)

Capacitances and inductances were calculated in the same manner as those for the solar array. Resistances were apportioned among the quadrant members.

3.9 Forward Mesh and Thermal Blanket (Series 90)

Radial inductances and resistances were calculated for the quadrants of the forward barrier in the same manner as for the equipment shelf. The capacitance of the antenna dish to the equipment shelf is also included.

3.10 Aft Structure and Aft Omni (Series 100)

The aft omni support and omni antenna were modeled similar to the forward omni.

4. ISPICE CALCULATION RESULTS

The results of the Table 3 currents used on the electrical model are presented in Table 8. In Regions I and II, the photocurrent was modeled as an offset sine function with the phase angle depending on the quadrant. For example, Source I has a phase of 0° , J has a phase of 90° , etc. The offset is chosen to make the photocurrent maximum at 90° and zero at 270° . This overestimates the photocurrent per spin cycle. A rectified sine curve would better approximate the photocurrent. In these regions, the effect of this pulsating current is seen as an ac voltage on the perimeter of the shelf. The magnitude of this voltage is shown in Regions I and II at the four shelf locations and for the exterior of the solar panel. The frequency for this oscillation is the reciprocal of the spacecraft spin period.

The only voltage to exceed 1 volt in Table 8 is that of the solar panel in Region II. Here we assume a fairly high photocurrent and a very low plasma temperature and density. The electron current is predominately a thermal current, the only current available to neutralize the photocurrent. Therefore, positive potentials are possible.

Table 8. ISPICE Calculations - 85 Percent Porosity

Node	ISPICE Run	Altitude (max)				
		200	350	700	1000	>1000 km
		V	IV	III	II	I
1	Omni antenna	-3.4	-11	-37	<1	24
3	Dish antenna	-1.9	-9.8	-37	<1	24
7	Antenna feed	-1.9	-9.5	-42	<1	21
8	Mesh	-1.9	-9.2	-37	<1	24
16	Solar panel extension	-1.9	-9.2	-37	<1	24 ± 0.04
22	Center of shelf	-1.9	-9.2	-37	<1	24

R40N1	Current through BAPTA, μA	-2.3	-17	-1.1	13.6	-7.8

* ±2333 mV.

NOTE: All voltages in millivolts unless otherwise noted.

Doubling the current densities in Table 2 will at most double the negative voltages for each region. In Regions I and II, the photocurrent still dominates and the voltages remain about the same.

Increasing the conductive mesh area does not significantly change the potentials on the spacecraft. Table 9 shows a series of calculations in which the area of the conductive mesh is calculated, assuming 0 percent porosity instead of 85 percent porosity. Modeling of the plasma and the spacecraft in this way is a new art and there are many areas of uncertainty. In extending these calculations, the ISPICE⁸ representation of nonlinear voltage controlled current sources for low temperature plasmas needs improvement, as does the representation of photocurrents on a spinning body. The effect of ram currents as a function of orbit position and orientation, and the investigation of sheath formation, plasma resistivity, and geometrical effects are also of interest.

Table 9. ISPICE Calculations - 0 Percent Porosity

Node	Altitude (max)	200	350	700	1000	>1000 km
