DESIGN AND EVALUATION OF LOW COST BLADES FOR LARGE WIND DRIVEN GENERATING SYSTEMS

W. S. Eggert, Chief Designer
The Budd Company Technical Center
NASA-Lewis Contract DEN 3-129

ABSTRACT

The program task was to develop a low cost blade concept, based on the NASA-Lewis specifications, and to evaluate its principle characteristics, its low cost features, advantages and disadvantages. A blade structure was designed and construction methods and materials were selected. Complete blade tooling concepts, various technical and economic analysis, and evaluations of the blade design were performed. A comprehensive fatigue test program was conducted to provide data and to verify the design. A test specimen of the spar assembly, including the root end attachment, has been fabricated. This is a full-scale specimen of the root end configuration, 20 ft long, and will be fatigue tested by NASA. A blade design for the Mod. "O" system has been completed.

OVERVIEW OF CONTRACT OBJECTIVES

The design of large wind turbine blades have conflicting requirements and criteria. Cost is the most sensitive requirement and structural reliability is the foremost criterion. The basic design is predicated on the premise that large blades should be an industrial product of predictable performance and uncomplicated structure. In order to be successful, rotors must be capable of being produced in volume at reasonable cost. The Budd Company draws upon its background and knowledge in fabrication of long-life carbon steel and stainless steel structures and mass fabrication of glass-reinforced structural parts. Fabricating techniques combined with a long history of successful product designs assures that the program objectives can be met.

BUDD DESIGN CONCEPT

In conventional design, the leading edge section, or the D
spar area of the blade, is used to carry the operating loads,
and the trailing edge is essentially non-structural, carrying
air loads for the trailing edge only. The Budd design does
not have a conventional forward D spar. The design uses a
central spine spar that is essentially non-dimensional rela-
tive to the aerodynamic surface; that is, it is a simple,
rectangular spar located within the envelope of the aerody-
namic contours. This spar carries all the basic edgewise
loading and all the basic flatwise loading and provides pri-
narily all the torsional stiffness for the blade system.

The leading edge and trailing edge fiberglass components are
designed to distribute the air loads to spar and are segmented
spanwise to prevent them from having to carry high loads in
the spanwise direction due to spar bending deflections. These
sections are bonded to the spar using an elastomeric adhesive.
The illustration is an idealized section cut at station 187 of
the blade. There is a center spar composed of spot welded
stainless steel. This structure is composed of top and bottom
cap strips, two shear webs, one on the front and one on the
aft side of the spar. This spar is built with a 10° twist
from the root end to the outer end. The leading edge and the
trailing edge of the assemblies are fabricated of fiberglass
reinforced plastic composed of multiple pieces that are then
filled with urethane foam. These fiberglass subassemblies
are bonded to the spar at the four flange corners of the spar.
The leading and trailing edge assemblies are also bonded and
mechanically fastened at the high camber point of the blade.
The leading edge of the blade is protected by an elastomeric
sheet to provide energy absorption due to impact of hail and
other abrasive elements. The leading and trailing elements
are designed so as not to contribute significantly to the
structural stiffness of the blade.
TYPICAL SECTION

WIND TURBINE BLADE

Shown is an exploded view of the spar assembly. The spar is composed of four sub-assemblies, an upper and lower cap strip plate assembly and a front and rear spar web assembly. The selection of stainless steel and the spot weld process provides a unique method by which the spar stiffness can be effectively tapered to provide a near uniform stress from the root end to the tip of the spar. This tapering is accomplished by the use of tapered angles that are spot welded together and are joined to the upper and lower cap strip plate. The thickness of the top plates are tapered in three steps using a butt arc weld to join each thickness. This is a specialized process that was developed during the Budd 301 testing program. This provides a weld of high reliability in fatigue strength. By controlling this taper, we are able to provide uniform tapering of the basic properties of the spar section. The angles are first tapered in the blank and, as a result, there is essentially no material lost. The angles are then formed and then spot welded to the spar cap assembly. This is all done in the flat and then they are elastically twisted to match the 10° twist of the spar. The spar webs are composed of two angles and spar web. The two angles and web are spot welded in place to form the web for the spar. There are two of these. These are also built flat and elastically twisted to form the 10° twist to the spar. The four assemblies are then assembled into an assembly fixture with the 10° twist provided and are spot welded together. This provides a very efficient tapering of the spar without machining and at a very low cost, using rolled sheet material. The use of stainless steel also provides excellent corrosion protection for long life of the spar. Spot welding provides a low cost, reliable, efficient assembly process to assemble the spar at a low cost.
The illustration shows a breakout of all the major sub-
assemblies of the blade.
The illustration on the following page shows an exploded view
of the leading edge and trailing edge assemblies. These as-
semblies are composed of low cost layup of fiberglass-reinforced
polyester. A commercial grade of this material is used. Fiber-
glass elements are parasitic to the primary spar structure and
are used only to distribute the air loads to the spar. Their
design requirements are minimal. To stabilize these elements
for fatigue, the fiberglass elements are filled with a semi-
rigid, urethane foam of approximately 2 1/2 pounds per cubic
foot density. This provides a light-weight, well-damped struc-
ture for the leading and trailing edge assemblies and prevents
aerodynamic flutter of lightweight surfaces. This design permits
accurate dimensional control of the aerodynamic surfaces at low
relative cost.

To reduce weight and to improve mass distribution in the blade, the metal spar is cut short and a structural fiberglass tip extension is used. The illustration shows a breakout view of the tip parts.
271

The final assembly of the blade is accomplished in two major
steps. The trailing edge assemblies are bonded to the spar.
Working from the inboard end of the blade outboard, the lead-
ing edges are then assembled to the spar trailing edge major
assembly by bonding and mechanical fastening, working from
the inboard end outboard. The tip assembly is then bonded and
mechanically joined to the blade assembly. The final step is
the installation of elastomeric sealing strips between the
edges of the fiberglass assemblies to provide aerodynamic seal-
ing of the surfaces.

TRAILING EDGES TO SPAR ASSEMBLY
## LEADING EDGES AND TIP TO SPAR ASSEMBLY

A study to determine whether the basic concept of the design could be utilized through the entire range of blade sizes was made. The basic concept of a rectangular spar inside the aerodynamic surface carrying the principal loads with parasitic aerodynamic elements directing the air loads into the spar can be applied to the entire range of blades. The illustration below shows the blades that were reviewed in this study. Using the present configuration, with a high aspect ratio blade, we would use a stainless steel spar from the 60-foot size blade down to the smaller sizes. The advantage of the stainless steel spar is the ability to taper and spot weld the assemblies together at low cost and with good corrosion resistance for the thinner gage materials needed on the smaller blades. From the 60-foot blade on up, we would use a high strength, low alloy carbon steel for the spar. The reason for this is that the gage of the materials will be out of the range of those producible in stainless steels. Thicker gage cryogenic stainless steel material might be used, but we do not think this would be economically feasible in the larger size.

The illustration below shows the basic spar configuration for the 60-foot blade. This is constructed of 301 1/4 hard .125 thick stainless steel. Also shown is the general configuration of a spar of 200 ft length. It was basically the same design concept used for a 150-foot blade.

Our first cursory judgements are that it may be more practical to produce, at a lower cost, a multiplicity of smaller blades rather than a low quantity of larger blades for the same power output. Since the blade is only a small percentage of the total system, this conclusion may not hold when the whole system is considered.

Larger blades enter into an area of manufacturing which is beyond the present state of the art in many areas. To provide a good, low cost design will require considerable investigation. In the area of transportation, a blade up to 85 feet in length can be shipped in one piece without major difficulty. Above that size, the blades would have to be shipped in multiple pieces. This, of course, increases the problems of design of the blade, inasmuch as this would require spar joints outboard in the blade that would have to have the same degree of reliability as the root fitting. This can add considerable weight and cost but can be done. We are doing further investigation into the effects of varying lengths on design and their relative cost and weight.

FATIGUE STRENGTH QUALIFICATION PROGRAM

In this section, we present a summary of the fatigue test
program and the structural analysis. It covers the test-
ing and the development of the allowable stresses used in
the design. Summarized are the structural properties of
the blade design. Testing of the fiberglass structures are
discussed. The fatigue test program conclusions and the
final blade design configuration were presented to NASA-Lewis
on October 20, 1980. The illustration shows the configura-
tion developed for the fatigue testing program. Considerable
development was required to be able to perform satisfactory
fatigue tests on the large full scale test specimens.
Parallel with the NASA full scale test element program, The
Budd Company has conducted an in-house fatigue test program
to obtain long term fatigue data on 301 stainless steel and
the effects of joining techniques as related to long term
fatigue. See the following series of illustrations and tables
for the test results. We have used data from this program to
supplement the full scale testing conducted under the NASA
contract.

The 301 test series has been used to obtain base metal prop-
erties. All tests were run to 10 million cycles or more in
tension -tension fatigue at +0.1 R value. Data presented
are the minimum values without failures and have been adjusted
to the blade design level of -0.5 R value using Goodman dia-
grams.

FLATWISE BENDING LOADS

BLADE WEIGHT DISTRIBUTION

SPAR MOMENT OF INERTIA
Computed blade assembly natural frequencies are 1.86 Hz in the
flatwise direction and 2.15 Hz in the edgewise direction.

A test specimen was designed and manufactured to be used to
determine manufacturing feasibility for the aerodynamic sur-
faces and to provide the fatigue test data for the system.

The illustration lists the basic materials used for the aero-
dynamic surfaces and shows the test specimen used to evaluate
the fatigue strength of the system. Weights were bonded over
the aerodynamic surfaces equivalent to 1/2 the maximum aerody-
namic load distribution. The specimen was then cycled $\pm$ 1 G
to produce a 0 to 1 G load factor for the aerodynamic load and,
as a function of the mass of the test specimen, a cyclic load
of $\pm$ 1 G for the mass of the section. Additional tests were
run as shown in the summary data on the next page. The results
of the tests are excellent and indicate the design is conserva-
tive.

ROOT END TEST BEAM

To provide confirmation of the spar design, a full scale root
end test section has been manufactured. This specimen was
designed to apply the design load to the root end attachment
fitting and at a zone approximately 6 ft from the root end
to provide the maximum bending stresses in the spar deter-
mined by the analysis.

Shown in the illustration is the design of the root end beam.
Analysis has shown that one way to accomplish a representative
test is to apply opposing loads. This permits us to obtain a
balance of the maximum cyclic stress on the spar and the maxi-
mum shear load on the assembly (top and bottom assemblies to
side assemblies) spot welds. At the same time, the maximum
moment and stresses are produced at the root end attachment.
The loads described induce the maximum stresses used in the
analysis. These are not the actual test loads. Testing levels
will be adjusted to match NASA operating experience.

COST STUDY 125 FT ROTOR

A comprehensive cost and weight analysis of the blade design has been made. The design was processed in detail and we have costed the blade as a function of the individual processes for each part and assembly.

The table shows the cost and weights of the blade and major sub-systems based on 100 units per year. The final blade design weighs less than 2,500 lbs.

CONCLUSION

The Budd Company completed Phase I of the contract. The Phase II program (Building of a Flight Set of Blades) is on hold pending future decisions on the need for blades for 125 ft diameter rotor systems and the funding for such systems. The trend of the wind energy program to build larger systems in the 300 ft rotor size requires further design study. We are very encouraged with the overall design concept and its many advantages when applied to larger systems. The concept permits the use of more complex air-foil systems with minimum effects on costs. It permits modular construction of all elements of the blade system which significantly improves producibility when applied to high volume production. The Budd Company is presently working on designs for application to large rotor systems and is available as a supplier to build such systems.
