Abstract

**Background:** A number of epidemiological studies have examined the adverse effect of air pollution on mortality and morbidity. Also, several studies have investigated the associations between air pollution and specific-cause diseases including arrhythmia, myocardial infarction, and heart failure. However, little is known about the relationship between air pollution and the onset of hypertension. **Objective:** To explore the risk effect of particulate matter air pollution on the emergency hospital visits (EHVs) for hypertension in Beijing, China. **Methods:** We gathered data on daily EHV's for hypertension, fine particulate matter less than 2.5 μm in aerodynamic diameter (PM$_{2.5}$), particulate matter less than 10 μm in aerodynamic diameter (PM$_{10}$), sulfur dioxide, and nitrogen dioxide in Beijing, China during 2007. A time-stratified case–crossover design with distributed lag model was used to evaluate associations between ambient air pollutants and hypertension. Daily mean temperature and relative humidity were controlled in all models. **Results:** There were 1,491 EHV's for hypertension during the study period. In single pollutant models, an increase in 10 μg/m$^3$ in PM$_{2.5}$ and PM$_{10}$ was associated with EHV's for hypertension with odds ratios (overall effect of five days) of 1.084 (95% confidence interval (CI): 1.028, 1.139) and 1.060% (95% CI: 1.020, 1.101), respectively. **Conclusion:** Elevated levels of ambient particulate matters are associated with an increase in EHV's for hypertension in Beijing, China.

Key Words: Particulate air pollution; Emergency hospital visit; Hypertension; Time-stratified case–crossover;
Particulate air pollution and hypertension

Introduction

Air pollution is a very serious issue for human health, particularly in urban areas in developing countries. Outdoor particulate air pollution was estimated to be responsible for about 0.8 million premature deaths and 6.4 million years of lost life worldwide (Cohen et al., 2005). Recently, numerous epidemiological studies have examined the effect of air pollution on mortality, hospital admissions, and emergency hospital visits (EHVs) for cardiovascular diseases, respiratory diseases, and cardiopulmonary diseases (Guo et al., 2009; Halonen et al., 2009; Oudin et al., 2009; Simkhovich et al., 2009). Additionally, some studies have shown that the ambient air pollution increased the risks of cause-specific cardiac disease e.g. coronary disease (Kan et al., 2008; Simkhovich et al., 2009), arrhythmia (Chiu and Yang, 2009; Santos et al., 2008), myocardial infarction (D'Ippoliti et al., 2003), and heart failure (Lee et al., 2008; Wellenius et al., 2006). However, few data are available on the potential impact of particulate air pollution on acute events for hypertension.

Research conducted in Beijing, China shows that about 47% of people have hypertension, which is defined by systolic blood pressure greater than 140 mmHg and diastolic blood pressure greater than 90 mmHg (Xu et al., 2008). In the United States, the number of deaths caused by hypertension rose by 53% from 1991 to 2001 (Wexler, 2007). 91 percent of people with heart failure had preceding hypertension, and half of all patients who suffered a heart attack (and two thirds of those who had a first-time stroke) had blood pressure greater than systolic blood pressure 140 mmHg and diastolic blood pressure 90 mmHg (Wexler, 2007).

Human exposure, animal experiments and epidemiological studies have illustrated that particulate air pollution potentially raises blood pressure (Brook, 2005), even in healthy
Particulate air pollution and hypertension

individuals (Urch et al., 2005). At present, however, it is unknown whether particulate air pollution induces acute hypertension events in persons with preexisting hypertension. Therefore, we used a time-stratified case–crossover design to analyse the relationship between ambient air pollution and EHV for hypertension, and aimed to discover whether a short-term increase in ambient air pollution is associated with the onset of hypertension.

Materials and methods

1. Data on emergency hospital visits

Data on EHV for hypertension were gathered between Jan and Dec 2007 from the Peking University Third Hospital, located in the northwest part of Beijing (Guo et al., 2009). The information of each case includes: age, gender, occupation, diagnostic code, living address and primary diagnosis. The primary diagnoses of daily EHV were coded according to the International Classification of Disease, 10th revision for hypertension (ICD10: I10). The EHV for hypertension were diagnosed by the visiting patients’ symptoms, inquiries, and medical inspections. Therefore, we expect the misclassification rate to be relatively small. About 95% of visits for hypertension are diagnosed only with hypertension, while 5% have accompanying heart failure, myocardial infarction or other diseases. The cases enrolled in this study had lived in the resident areas around the hospital or in urban areas of Beijing.

2. Data on air pollution and weather condition

Data on particulate matter less than 2.5 μm in aerodynamic diameter (PM$_{2.5}$) was monitored on the campus of Peking University, which is about four kilometres away from the Peking University Third Hospital. Daily average concentration of PM$_{2.5}$ was transformed from hourly values. Daily records of particulate matter less than 10 μm in aerodynamic diameter (PM$_{10}$), sulfur dioxide (SO$_2$), and nitrogen dioxide (NO$_2$) were obtained from the Beijing Public Net for Environmental Protection of Beijing Municipal Environmental...
3. Data analysis

In this study, the time-stratified case–crossover design was used to analyse the relationship between particulate air pollution and EHV for hypertension. The case–crossover design compares the exposure in the case period when events occurred with exposures in nearby control periods, to examine the differences in exposure which can be used to explain the differences in the daily number of cases. The case–crossover design can control confounders related to individual characteristics, e.g. age, sex, and smoking. The secular trends and seasonal patterns in the disease and exposures can also be successfully controlled by case–crossover design. The cases and controls were matched by the day of the week to control any weekly patterns in hospital visits and pollution levels. The length of the time strata was 28 days, so each case had three matching control days. Simulations have shown that this approach gives unbiased estimates in the presence of strong seasonal confounding (Basu et al., 2005; Lee and Schwartz, 1999).

To examine the delayed effect of exposure to air pollution on the onset of hypertension, we used a polynomial distributed lag model (Armstrong, 2006; Schwartz, 2000). The reason for using the distributed lag model is that air pollution can affect not merely health events occurring on the same day, but on several subsequent days. Therefore, EHV for hypertension today would depend on the “same day” effect of the current day’s pollution levels and the lag effects of the previous days’ pollution concentrations. The polynomial distributed lag model (PDL (q, d) with q lags and degree d), the most common approach to constrain the shape of the variation of the \([\beta_q]\)’s with lag number, was used to gain more
efficiency and more insight into the shape of the distributed effect of air pollution on EHV
for hypertension over time (Schwartz, 2000). We examined the lag effect of exposure to air
pollution on EHV for hypertension up to four days prior to the hospital visit, because there
were no apparent effects of PM\textsubscript{2.5} and PM\textsubscript{10} on EHV for hypertension when the lags were
more than five days. The polynomial smoothing with four degrees of freedom for PM\textsubscript{2.5} and
PM\textsubscript{10} was used in the models (Santos et al., 2008). The overall effects (over all five days) on
EHVs for hypertension associated with a 10 \(\mu\text{g/m}^3\) increase, as well as an inter-quartile
range (IQR) increase, in PM\textsubscript{2.5} and PM\textsubscript{10} were calculated in this study.

Daily mean temperature and relative humidity were controlled in all models (Braga et
al., 2001). Single and multiple air pollutants models were used to examine the independent
effects of air pollutants. Odds ratios (Ors) and confidence intervals (CIs) were calculated for
each pollutant, and all statistical tests were two-sided. Values of \(P<0.05\) were considered
statistically significant, and spearman correlation coefficients were used to summarise the
correlations between weather conditions and air pollutants. The “season” package of the R
software (version 2.10.1) was used to fit the time-stratified case–crossover (Barnett, 2010),
and the “dlnm” package was used to fit the polynomial distributed lag model in the
time-stratified case–crossover design (Armstrong, 2006).

**Results**

During the study period, there were 1,491 EHV for hypertension in the Peking
University Third Hospital. The patients’ average age was 61 years. 51 percent of the cases
were aged <65 and 35.4% were males.

The descriptive statistics for air pollutants and weather conditions are shown in Table 1.
The IQRs for PM\textsubscript{2.5} and PM\textsubscript{10} were 76.3 \(\mu\text{g/m}^3\) and 88.0 \(\mu\text{g/m}^3\), respectively. The levels of
PM\textsubscript{10} and NO\textsubscript{2} were higher than the national secondary ambient air quality standard in China
(100 μg/m³ and 40 μg/m³ respectively), while the level of SO₂ did not surpass the national secondary ambient air quality standard in China (60 μg/m³). The standard for PM₂.5 air pollution has not been set in China, but the mean concentration of PM₂.5 air pollution was higher than the ambient air quality standard in the United States (35 μg/m³, National Ambient Air Quality Standards of United States).

Table 2 presents Spearman correlation coefficients between air pollutants and weather conditions. PM₂.5, SO₂, and NO₂ were positively correlated with each other, as well as PM₁₀, SO₂ and NO₂ (P<0.05). Temperature was positively correlated with PM₂.5 (r=0.22, P<0.05). A positive correlation was found between humidity and PM₂.5 (r=0.34, P<0.05) and PM₁₀ (r=0.28, P<0.05).

Figure 1 shows the distributed lag structures of effects on EHVs for hypertension caused by a 10 μg/m³ increase in PM₂.5 and PM₁₀ using fourth-degree polynomials ranging from lag 0 to lag 4. Both PM₂.5 and PM₁₀ were significantly associated with EHVs for hypertension on the two-day lag, even after adjusting for SO₂ and NO₂.

Table 3 presents the overall effects (over all five days) of air pollutants on EHVs for hypertension associated with a 10 μg/m³ increase and an IQR increase in single and multiple pollutant models. In the single pollutant models, the overall effects on EHVs for hypertension associated with a 10 μg/m³ increase in PM₂.5 and PM₁₀ were 1.084 (95%CI: 1.028, 1.139) and 1.060 (95%CI: 1.015, 1.106), respectively. After controlling SO₂ and NO₂, the overall effects of both PM₂.5 and PM₁₀ were lower than the single air pollutant models.

Figure 2 shows that the adverse effects were greatest for the highest concentrations of PM₂.5 and PM₁₀, and the peak in EHVs for hypertension was one day after exposure.

Discussion

In this study, the time-stratified case–crossover design with polynomial smoothing was
used to analyse the impact of particulate air pollution on EHV\textsubscript{s} for hypertension in Beijing, China. We found a positive relationship between particulate air pollution and EHV\textsubscript{s} for hypertension. The statistically significant two-day lag effects were found for both PM\textsubscript{2.5} and PM\textsubscript{10}.  

Because studies of air pollution effects on hypertension morbidity or specifically EHV\textsubscript{s} for hypertension are unusual, it is hard to compare results with previous research. However, some studies have found that increased concentrations of air pollution can elevate blood pressure. Johnson and Parker (2009) used data from a large, nation-wide survey in the United States in which subjects were 30 years or older. This study found that PM\textsubscript{2.5} was associated with a small elevated risk of hypertension. Auchincloss et al. (2008) examined cross-sectional associations between short-term ambient PM\textsubscript{2.5} and systolic and diastolic blood pressure, mean arterial pressure, and pulse pressure, and found that systolic blood pressure and pulse pressure were positively associated with ambient levels of PM\textsubscript{2.5} and the associations were stronger in the presence of roadway traffic. Brook et al. (2009) found that particulate matter was responsible for increasing diastolic blood pressure, probably by instigating an acute autonomic imbalance.  

Several biologic mechanisms shown in previous studies also support the results in our study. Hazari et al. (2009) found that a single exposure to particulate matter or gaseous pollutant increases the risk of aconitine-induced cardiac arrhythmia in hypertensive rats. Bartoli et al. (2009) used dogs and concentrated ambient air particles to investigate the effect of ambient particles on systemic hemodynamics, and found that exposure to concentrated ambient air particles ranging from 94.1 to 1557.0 $\mu$g/m\textsuperscript{3} increased systolic blood pressure by an average of 2.7 mmHg, diastolic blood pressure by 4.1 mmHg, mean arterial pressure by 3.7 mmHg, heart rate by 1.6 beats per minute, and decreased pulse pressure by 1.7 mmHg. Sun et al. (2008) found that when rats were exposed to PM\textsubscript{2.5} or filtered air for 10 weeks, air...
pollution exposure potentiates hypertension through reactive oxygen species-mediated activation of Rho/ROCK. Schins et al. (2004) found that exposure to PM$_{2.5}$ was significantly associated with endotoxin content, interleukin (IL)-8 and TNF alpha from the whole blood of rats. Ito et al. (2008) used mRNA expression and correlation analyses to examine how PM$_{2.5}$ induced the oxidative stress (a key cause of cardiovascular disease), and found that chemicals in concentrated ambient particles might be transmitted to the heart where they induce oxidative stress and activate endothelin signaling, resulting in an increase in the blood pressure. Other research has found associations between air pollution and acute arterial vasoconstriction (Brook et al., 2002), C reactive protein (Pekkanen et al., 2000; Pope et al., 2004; Schwartz, 2001), and heart rate variability (Cavallari et al., 2008; Fang et al., 2009). Because the aconitine-induced cardiac arrhythmia, blood pressure, reactive oxygen species-mediated activation, endotoxin, interleukin (IL)-8 and TNF alpha, arterial vasoconstriction, and heart rate variability are directly or indirectly related to the function of cardiovascular system, the increase in particle air pollution may induce the onset of hypertension.

The results of our study suggested that exposure to PM$_{2.5}$ has a greater effect than PM$_{10}$ on EHV$s$ for hypertension per 10 µg/m$^3$ increase, as well as an increase in IQR (Table 3). Compared with PM$_{10}$, PM$_{2.5}$ can stay in the air for a longer time. PM$_{2.5}$ can also be breathed into the respiratory tract and directly inhaled into the pulmonary alveoli from where blood circulation can take PM$_{2.5}$ to the cerebral-vascular system. Besides, PM$_{2.5}$ has a larger superficial area than PM$_{10}$, thus adsorbing more types of chemical elements than PM$_{10}$. Therefore, PM$_{2.5}$ might be more harmful on population health than PM$_{10}$ (Yang, 2003).

In the multiple pollutants models, the ORs of PM$_{2.5}$ and PM$_{10}$ were lower than single pollutant models. Previous research (Guo et al., 2009; Yang, 2008) on air pollution and mortality and EHV$s$ for cardiovascular diseases in Beijing found similar associations to
those shown here. These results may suggest that air pollutants share health effects. The lower effect of PM pollution on EHV for hypertension in the multiple pollutants models may be caused by their statistical co-linear effect.

The time stratified case–crossover design has the ability to control many confounders by design, such as age, gender, smoking, drinking, living custom, and so on. By matching on the day of the week, we avoid confounding due to generally higher pollutant levels on weekdays. The case–crossover also successfully controls seasonal patterns and long-term trends (Basu et al., 2005; Lee and Schwartz, 1999; Navidi, 1998; Neas et al., 1999). We checked the model sensitivity by moving monthly data, and found similar outcomes. Although our sample size is not large, the results already show a statistically significant relationship between particulate air pollution and EHV for hypertension. Therefore, the results are reliable in this study.

The strength of this study is: EHV reflects the association between air pollution and acute events of diseases more accurately than hospital admission, because when people in China with cardiovascular diseases feel uncomfortable, the first choice they usually make is to visit the hospital emergency department.

This study also has some limitations. The health data was collected from only one hospital and data on PM$_{2.5}$ was gathered from only one monitor station. Therefore, the selecting confounding might exist. Ambient air pollution was used rather than individual exposure. The diagnosis for EHV for hypertension could not be 100% correct. It might cause the misclassification confound.

**Conclusion**

In this case–crossover study, we found that elevated concentrations of ambient particulate matter air pollutants were associated with an increase in the EHV for
Particulate air pollution and hypertension

hypertension in Beijing during 2007. The findings provide additional information about the health effects of air pollution in Beijing, China, and may have implications for local environmental and public health.
