37

## 38 INTRODUCTION

39

40 Dussertite is a rare member of the crandallite group, which belongs to a large family  
41 of isostructural compounds having the general formula  $AB_3(XO_4)(OH, H_2O)_6$ , where A =  
42  $M^+$ ,  $M^{2+}$ ,  $M^{3+}$  and/or  $M^{4+}$  cations, B =  $M^{3+}$  (and minor  $M^{2+}$  cations, such as  $Cu^{2+}$ ,  $Zn^{2+}$  and  
43  $M^{5+}$ , such as  $Nb^{5+}$  and  $Ta^{5+}$ ), and X =  $P^{5+}$ ,  $As^{5+}$ ,  $S^{6+}$ ,  $Cr^{6+}$  and minor  $Si^{4+}$  <sup>1</sup>. There are some  
44 discrepancies in its chemical formula reported in the literature  $BaFe^{3+}_3(AsO_4)_2(OH)_5$  <sup>2</sup>,  
45  $BaFe_3(AsO_4)_2(OH, H_2O)_6$  <sup>1,3</sup>. Walenta ascribed to dussertite the chemical formula  
46  $BaFe_3H(AsO_4)_2(OH)_6$  <sup>4</sup> and later  $BaFe_3(AsO_4)_2(OH)_5 \cdot H_2O$  <sup>5</sup>. This agrees with the formula  
47 published by Winchell and Winchell <sup>6</sup> and Fleischer *et al.* <sup>7</sup>. Thus, the question if dussertite  
48 contains molecular water in its structure remains open. The mineral dussertite is formed  
49 through the alteration of arsenopyrite <sup>2</sup> or other As-containing primary minerals under  
50 oxidising conditions. Kolitsch *et al.* <sup>1,8</sup> described the structure of antimonian dussertite, in  
51 which was inferred the substitution of  $Sb^{5+}$  for  $Fe^{3+}$  and not for  $As^{5+}$ . The space group of  
52 trigonal dussertite is  $R\bar{3}m$  and the unit-cell parameters are  $a = 7.4244(3)$  and  $c = 17.494(1)$   
53 Å,  $Z = 3$ . The crystal structure is of the alunite-type and consists of sheets of corner-sharing  
54  $(Fe^{3+}, Sb^{5+})O_6$  octahedra parallel to (0001). The icosahedrally coordinated  $Ba^{2+}$  cations  
55 occupy cavities between pairs of octahedral sheets and are surrounded by six oxygen atoms  
56 from the  $(Fe^{3+}, Sb^{5+})O_6$  octahedra. The possible presence of  $(AsO_3OH)^{2-}$  in the crystal  
57 structure of antimonian dussertite was not inferred from the structure analysis. On the  
58 contrary, in the refined crystal structure of analogous phosphate - gorceixite, the presence of  
59  $(PO_3OH)^{2-}$  groups was inferred in the disordered tetrahedral position of its crystal structure.

60

61 The aim of this paper is to report the Raman spectra of dussertite, and to relate the  
62 spectra to the molecular and crystal chemistry of this arsenate type mineral. The paper  
63 follows the systematic research on Raman and infrared spectroscopy of secondary minerals  
64 containing oxy-anions formed in the oxidation zone <sup>9-21</sup>.

65

## 66 EXPERIMENTAL

67

### 68 Minerals

69

70 The studied sample of the mineral dussertite was found at the open pit at Huber-stock  
71 deposit, Krásno near Horní Slavkov, Horní Slavkov ore district, the Slavkovský les

72 Mountains, western Bohemia, Czech Republic, and is deposited in the mineralogical  
73 collections of the National Museum, Prague. The sample was analysed for phase purity by X-  
74 ray powder diffraction. No minor significant impurities were found. Its refined unit-cell  
75 parameters for trigonal space group  $R\bar{3}m$ ,  $a$  7.3875(5),  $c$  17.484(1) Å,  $V$  826.4(1) Å<sup>3</sup><sup>22</sup>, are  
76 comparable with the data published for this mineral phase<sup>1, 22</sup>.

77

78 The dussertite sample was quantitatively analysed by Cameca SX100 microprobe  
79 system in wavelength dispersion mode for chemical composition. Studied sample was  
80 mounted into the epoxide resin and polished. The polished surface was coated with carbon  
81 layer 250 Å. An accelerating voltage of 15 kV, a specimen current of 10 nA, and a beam  
82 diameter of 5 - 10 µm were used. The following lines and standards were used:  $K\alpha$ : andradite  
83 (Ca, Fe), InAs (As), sanidine (Al, Si), fluorapatite (P), ZnO (Zn), baryte (S);  $L\alpha$ : diopside  
84 (Cu), SrSO<sub>4</sub> (Sr), W (W);  $L\beta$ : benitoite (Ba) and  $M\beta$ : Bi (Bi). Peak counting times (CT) were  
85 20 s for main elements and 60 s for minor elements. CT for each background was ½ of peak  
86 time. The raw intensities were converted to the concentrations using automatic *PAP* matrix  
87 correction software package. The results (mean of 3 point analysis) are CaO 0.45, BaO 17.22,  
88 SrO 0.31, CuO 0.46, ZnO 0.42, Fe<sub>2</sub>O<sub>3</sub> 28.54, Al<sub>2</sub>O<sub>3</sub> 2.72, Bi<sub>2</sub>O<sub>3</sub> 0.23, SiO<sub>2</sub> 1.65, As<sub>2</sub>O<sub>5</sub> 24.74,  
89 P<sub>2</sub>O<sub>5</sub> 1.43, SO<sub>3</sub> 0.14, WO<sub>3</sub> 5.92, H<sub>2</sub>O (5.71), the sum 89.94 wt. % and empirical formula  
90  $(\text{Ba}_{0.77}\text{Ca}_{0.06}\text{Cu}_{0.04}\text{Zn}_{0.04}\text{Sr}_{0.02})_{\Sigma 0.93}(\text{Fe}_{2.46}\text{Al}_{0.37})_{\Sigma 2.83}$   
91  $[(\text{AsO}_4)_{1.48}(\text{PO}_4)_{0.14}(\text{SiO}_4)_{0.19}(\text{WO}_4)_{0.18}(\text{SO}_4)_{0.01}]_{\Sigma 2.00}(\text{OH})_{4.37}$ . The observed charge deficit on  
92 cation sites (Ba, Fe<sup>3+</sup>) may be balanced by above mentioned reduction of the number of (OH)  
93 groups or by including of (AsO<sub>3</sub>OH)<sup>2-</sup> groups in the crystal structure of dussertite. This  
94 should be in agreement with the ideal formula BaFe<sub>3</sub>[AsO<sub>3</sub>(O,OH)]<sub>2</sub>(OH)<sub>6</sub> analogous to  
95 gorgeixite. The lower sums of analyses are caused by the porous nature of the mineral  
96 studied. Based upon the methods used for calculating the formulae of minerals as may be  
97 found in published papers<sup>22, 23</sup>, the most suitable basis for calculating the formula of  
98 dussertite is to use the elements included in anion part of the formula - (As+P+Si+W+S) =  
99 2.00 apfu. H<sub>2</sub>O content was calculated on the basis of charge balance.

100

101 The Raman spectra of two dussertite minerals from Djebel Debar, Algeria and from  
102 Clara mine, Rankach Valley, Oberwolfach, Wolfach, Black Forest, Baden-Württemberg, and  
103 Germany<sup>24</sup> were downloaded from the RRUFF data base web site  
104 (<http://rruff.info/dussertite/display=default/>). The spectra were used as is and were not

105 modified in any way. The chemical analysis of the dussertite from Algeria can be found in  
106 Anthony *et al.* (page 152) <sup>2</sup>.

107

### 108 **Raman spectroscopy**

109

110 Crystals and single crystal samples of dussertite were placed on a polished metal  
111 surface on the stage of an Olympus BHSM microscope, which is equipped with 10x, 20x, and  
112 50x objectives. The microscope is part of a Renishaw 1000 Raman microscope system, which  
113 also includes a monochromator, a filter system and a CCD detector (1024 pixels). The Raman  
114 spectra were excited by a Spectra-Physics model 127 He-Ne laser producing highly polarised  
115 light at 633 nm and collected at a nominal resolution of 2 cm<sup>-1</sup> and a precision of ± 1 cm<sup>-1</sup> in  
116 the range between 200 and 4000 cm<sup>-1</sup>. Repeated acquisition on the crystals using the highest  
117 magnification (50x) were accumulated to improve the signal to noise ratio in the spectra.  
118 Spectra were calibrated using the 520.5 cm<sup>-1</sup> line of a silicon wafer. Previous studies by the  
119 authors provide more details of the experimental technique. Alignment of all crystals in a  
120 similar orientation has been attempted and achieved. However, differences in intensity may  
121 be observed due to minor differences in the crystal orientation.

122

### 123 **Infrared spectroscopy**

124

125 Infrared spectra of dussertite sample were recorded by micro diffuse reflectance  
126 method (DRIFTS) on a Nicolet Magna 760 FTIR spectrometer (range 4000-600 cm<sup>-1</sup>,  
127 resolution 4 cm<sup>-1</sup>, 128 scans, 2 level zero-filling, Happ-Genzel apodization), equipped with  
128 Spectra Tech InspectIR micro FTIR accessory. Each sample of amount less than 0.050 mg  
129 was mixed without using pressure with KBr. Samples were immediately recorded together  
130 with the same KBr as a reference.

131

132 Spectral manipulation such as baseline correction/adjustment and smoothing were  
133 performed using the Spectralcalc software package GRAMS (Galactic Industries Corporation,  
134 NH, USA). Band component analysis was undertaken using the Jandel 'Peakfit' software  
135 package that enabled the type of fitting function to be selected and allows specific parameters  
136 to be fixed or varied accordingly. Band fitting was done using a Lorentzian-Gaussian cross-  
137 product function with the minimum number of component bands used for the fitting process.

138 The Gaussian-Lorentzian ratio was maintained at values greater than 0.7 and fitting was  
139 undertaken until reproducible results were obtained with squared correlations of  $r^2$  greater  
140 than 0.995.

141

## 142 RESULTS AND DISCUSSION

143

144 The polyhedron  $(\text{AsO}_4)^{3-}$  is of tetrahedral symmetry ( $T_d$ ), exhibiting four fundamental  
145 vibrations: the  $\nu_1$  symmetric stretching vibration ( $A_1$ ,  $\sim 820 \text{ cm}^{-1}$ , Raman active), the doubly  
146 degenerate  $\nu_2$  symmetric bending vibration ( $E$ ,  $\sim 350 \text{ cm}^{-1}$ , Raman active), the triply  
147 degenerate  $\nu_3$  antisymmetric stretching vibration ( $F_2$ ,  $\sim 900\text{--}850 \text{ cm}^{-1}$ , Raman and infrared  
148 active) and the triply degenerate  $\nu_4$  bending vibration ( $F_2$ ,  $\sim 400 \text{ cm}^{-1}$ , Raman and infrared  
149 active)<sup>25-32</sup>. The  $(\text{AsO}_4)^{3-}$  group is the only tetrahedral oxyanion of the main group elements,  
150 exhibiting  $\nu_s > \nu_{as}$ <sup>29,33</sup>. Protonation, metal complexation, and/or adsorption on a mineral  
151 surface should cause change in  $(\text{AsO}_4)^{3-}$  symmetry from  $T_d$  to lower symmetries, such as  $C_{3v}$ ,  
152  $C_{2v}$  or  $C_1$ . This loss of degeneracy causes splitting of degenerate vibrations of  $(\text{AsO}_4)^{3-}$  and  
153 the shifting of the As-OH stretching vibrations to different wavenumbers. Such chemical  
154 interactions reduce  $(\text{AsO}_4)^{3-}$  tetrahedral symmetry, as mentioned above, to either  $C_{3v}/C_3$   
155 (corner-sharing),  $C_{2v}/C_2$  (edge-sharing, bidentate binuclear), or  $C_1/C_s$  (corner-sharing, edge-  
156 sharing, bidentate binuclear, multidentate)<sup>28,29</sup>. In association with  $(\text{AsO}_4)^{3-}$  symmetry and  
157 coordination changes, the  $A_1$  band may shift to different wavenumbers and the doubly  
158 degenerate  $E$  and triply degenerate  $F$  modes may give rise to several new  $A_1$ ,  $B_1$ , and/or  $E$   
159 vibrations. In the absence of symmetry deviations,  $(\text{AsO}_3\text{OH})^{2-}$  in  $C_{3v}$  symmetry exhibit the  
160  $\nu_s$  and  $\nu_{as}$  As-O vibrations ( $\text{As-O}_3$ ) and  $\nu_{as}$  and  $\nu_s$  As-OH vibrations<sup>28,29</sup>. The increase of As-  
161 OH bond-lengths cause shift of pertinent vibrations to lower wavenumbers. Myneni et al.<sup>28</sup>,  
162<sup>29</sup> discussed only the stretching vibrations. The correct assignments are thus extremely  
163 difficult. The resolution of the As-OH bands properly is nearly impossible without  
164 deuteration of the samples<sup>29</sup>. Keller<sup>34</sup> assigned the following infrared bands observed in the  
165 compound  $\text{Na}_2(\text{AsO}_3\text{OH})\cdot 7\text{H}_2\text{O}$  at  $450$  and  $360 \text{ cm}^{-1}$  to the  $\delta_{as}(\nu_4)$   $(\text{AsO}_3\text{OH})^{2-}$  bend ( $E$ ),  $580$   
166  $\text{cm}^{-1}$  to the As-OH out-of-plane bend,  $715 \text{ cm}^{-1}$  to the  $\nu$  As-OH stretch ( $A_1$ ),  $830 \text{ cm}^{-1}$  to the  
167  $\nu_{as}$   $(\text{AsO}_3\text{OH})^{2-}$  stretch ( $E$ ), and  $1165 \text{ cm}^{-1}$  to the  $\delta$  As-OH in-plane-bend. The Keller's  
168 suggested As-OH in-plane and out-of plane bending vibrations are comparable with similar  
169 attribution presented for  $\delta$  P-OH in-plane and  $\gamma$  P-OH out-of-plane bending vibrations<sup>34</sup>. In

170 the Raman spectrum of  $\text{Na}_2(\text{AsO}_3\text{OH})\cdot 7\text{H}_2\text{O}$ , Vansant *et al.*<sup>31, 32</sup> attributed observed Raman  
171 bands to the following vibrations: these at 55, 94, 116 and  $155\text{ cm}^{-1}$  to the lattice modes; at  
172  $210\text{ cm}^{-1}$  to the  $\nu(\text{OH}\dots\text{O})$  stretch; at  $315\text{ cm}^{-1}$  to the  $(\text{AsO}_3\text{OH})^{2-}$  rocking; at  $338\text{ cm}^{-1}$  to the  
173  $\delta_s\text{ AsO}_3$  bend;  $381\text{ cm}^{-1}$  to the  $\delta_{\text{as}}(\text{AsO}_3\text{OH})^{2-}$  bend; at  $737\text{ cm}^{-1}$  to the  $\nu_s\text{ As-OH}$  stretch ( $A_1$ );  
174 at  $866\text{ cm}^{-1}$  to the  $\nu_{\text{as}}(\text{AsO}_3\text{OH})^{2-}$  stretch ( $E$ ). Because of relatively high content of  $\text{P}^{5+}$  ( $\sim 0.14$   
175 apfu), also bands related to the  $(\text{PO}_4)^{3-}$  and  $(\text{PO}_3\text{OH})^{2-}$  vibrations are expected to be observed  
176 in the Raman and infrared spectra ( $(\text{PO}_4)^{3-}$ :  $\delta_s(\nu_2)$   $410\text{-}490\text{ cm}^{-1}$ ,  $\delta_{\text{as}}(\nu_4)$   $510\text{-}670\text{ cm}^{-1}$ ,  $\nu_1$   
177  $930\text{-}990\text{ cm}^{-1}$ ,  $\nu_3$   $975\text{-}1140\text{ cm}^{-1}$ ;  $(\text{PO}_3\text{OH})^{2-}$ :  $\delta(\text{O}_3\text{PO})$   $350\text{-}580\text{ cm}^{-1}$ ,  $\gamma\text{ POH}$   $700\text{-}900\text{ cm}^{-1}$ ,  $\nu$   
178  $\text{POH}$   $860\text{-}915\text{ cm}^{-1}$ ,  $\nu_s\text{ PO}_3$   $940\text{-}1010\text{ cm}^{-1}$ ,  $\nu_{\text{as}}$   $1040\text{-}1170\text{ cm}^{-1}$ ,  $\delta\text{ POH}$   $1210\text{-}1400\text{ cm}^{-1}$ , and  
179 combination bands at  $1400\text{-}1750\text{ cm}^{-1}$ ), if they are Raman and/or infrared active<sup>35</sup>.

180

181

## 182 **Raman spectroscopy of dussertite**

183

184 Because the complete Raman spectra of the dussertite minerals from Algeria and Germany  
185 are not provided, the spectra were only shown up to  $1100\text{ cm}^{-1}$ . The complete infrared  
186 spectrum for dussertite from Krásno is given in Fig. S1. The results of the Raman and  
187 infrared spectral analysis are summarised in Table 1.

188

189 The Raman spectra of the mineral dussertite from three different localities in the 600  
190 to  $1000\text{ cm}^{-1}$  region are displayed in Fig. 1. In the spectral region from 700 to  $950\text{ cm}^{-1}$  a  
191 complex set of overlapping bands is observed. For the Algerian dussertite four bands are  
192 inferred from the deconvolution analysis at 722, 794, 819, 859 and  $893\text{ cm}^{-1}$ . According to  
193 Myneni *et al.*<sup>28, 29</sup>, the proposed assignment of these bands is as follows: (a) the band at  $893$   
194  $\text{cm}^{-1}$  is assigned to the uncomplexed  $\text{As-O}_3$   $\nu_3$  antisymmetric stretching mode of the  
195  $(\text{AsO}_3\text{OH})^{2-}$  polyhedron (b) the band at  $859\text{ cm}^{-1}$  is assigned to the uncomplexed  $\text{As-O}_3$   $\nu_1$   
196 symmetric stretching mode, due to its intensity (c) the band at  $819\text{ cm}^{-1}$  is ascribed to  $\text{As-OBa}$   
197 stretching mode (d) the band at  $794\text{ cm}^{-1}$  is ascribed to the  $\text{As-OFe}$   $\nu_1$  symmetric stretching  
198 mode (e) the band at  $722\text{ cm}^{-1}$  is assigned to the complexed  $\text{As-OH}$   $\nu_1$  symmetric stretching  
199 mode. The assignments of Ba- and Fe- stretching modes were derived based on different  
200 bond-lengths in highly-probable isostructural antimonian dussertite. But overlapping of the  
201  $\text{As-OM}^{2+/3+}$  bands with hydroxyl deformations is likely. For the German dussertite, Raman  
202 bands are observed at 808, 827, 864 and  $896\text{ cm}^{-1}$ . The assignment of the bands is the same as

203 for the Algerian dussertite. The bands in the Raman spectrum of the Czech dussertite are  
204 broader. Raman bands are observed at 674, 724, 754, 825, 859, 870 and 902  $\text{cm}^{-1}$ . The two  
205 high wavenumber bands at 870 and 902  $\text{cm}^{-1}$  are assigned to the As-O  $\nu_1$  symmetric  
206 stretching mode and As-O  $\nu_3$  antisymmetric stretching mode of the uncomplexed As-O  
207 bonds. Bands at 859 and 825  $\text{cm}^{-1}$  are attributed either to hydroxyl deformation modes or  
208 stretching As-OM<sup>2+/3+</sup> vibrations. The split band at  $\sim 700 \text{ cm}^{-1}$  containing shoulders is  
209 ascribed to complexed As-OH symmetric and antisymmetric stretching vibration. On the  
210 basis of these assignments it is proposed that all the minerals studied contain variable  
211 amounts of protonated (AsO<sub>4</sub>)<sup>3-</sup> groups in the (AsO<sub>3</sub>OH)<sup>2-</sup> form. Variation in the spectra  
212 between the three dussertite mineral samples may be attributed to differences in composition.  
213 The infrared spectrum of Czech dussertite in the 650 to 1000  $\text{cm}^{-1}$  region is shown in Fig. S2.  
214 The infrared spectrum compliments the Raman spectrum. Infrared bands are found at 810,  
215 852, 881, 913 and 938  $\text{cm}^{-1}$  as inferred from the deconvolution analysis. The infrared bands at  
216 913 and 938 are assigned to the As-O  $\nu_3$  antisymmetric stretching mode and the band at 881  
217  $\text{cm}^{-1}$  to the As-O  $\nu_1$  symmetric stretching mode, which is active in the infrared spectrum. The  
218 bands at 852 and 810  $\text{cm}^{-1}$  are assigned to the As-OM<sup>2+/3+</sup> stretching modes or hydroxyl  
219 deformation modes.

220  
221 The Raman spectra of dussertite in the 100 to 600  $\text{cm}^{-1}$  region are reported in Fig. 2.  
222 For the Algerian dussertite, Raman bands are observed at 358, 405, 462 and 471  $\text{cm}^{-1}$ . The  
223 two bands at 358 and 405  $\text{cm}^{-1}$  are attributed to the  $\nu_2$  (AsO<sub>4</sub>)<sup>3-</sup> bending mode. The two high  
224 wavenumber bands are assigned to the  $\nu_4$  (AsO<sub>4</sub>)<sup>3-</sup> bending mode. A similar set of bands may  
225 be found for the German dussertite. The two bands at 367 and 405  $\text{cm}^{-1}$  are ascribed to the  $\nu_2$   
226 (AsO<sub>4</sub>)<sup>3-</sup> bending vibration and the single band at 471  $\text{cm}^{-1}$  is assigned to the  $\nu_4$  (AsO<sub>4</sub>)<sup>3-</sup>  
227 bending mode. For the Czech dussertite, Raman bands are observed at 372 and 409  $\text{cm}^{-1}$ .  
228 These bands may be attributed to the  $\nu_2$  (AsO<sub>4</sub>)<sup>3-</sup> bending vibration. The bands at 474  $\text{cm}^{-1}$   
229 and probably also at 429  $\text{cm}^{-1}$  are designated to the  $\nu_4$  AsO<sub>4</sub><sup>3-</sup> bending mode. In each of the  
230 spectra a band is observed in the 557 to 567  $\text{cm}^{-1}$  region. This band is attributed to the  $\nu_4$   
231 (AsO<sub>3</sub>OH)<sup>2-</sup> bending mode. As for the (AsO<sub>4</sub>)<sup>3-</sup> stretching region, there is a great deal of  
232 commonality between the three data sets despite the expected variation in composition. The  
233  $\nu_2$  (AsO<sub>4</sub>)<sup>3-</sup> bending vibration should be common to all hydroxyl arsenates, and should be  
234 relatively intense. Raman bands are observed at 350  $\text{cm}^{-1}$  for olivenite, 340  $\text{cm}^{-1}$  for  
235 cornwallite, and at 380  $\text{cm}^{-1}$  for clinoclase<sup>26</sup>.

236

237 Raman bands are observed in the far low wavenumber region in each of the spectra  
238 (Fig. 2). Three bands are observed at 208, 251 and 296  $\text{cm}^{-1}$  (Algerian), 202, 252 and 296  $\text{cm}^{-1}$   
239 (German), and 247, 275 and 306  $\text{cm}^{-1}$  (Czech). It is proposed that these bands are associated  
240 with Ba-O and Fe-O stretching vibrations. Intense bands at 188  $\text{cm}^{-1}$  (Algerian), 191  $\text{cm}^{-1}$   
241 (German), and 188  $\text{cm}^{-1}$  (Czech) are considered to be associated with the OH units and it is  
242 proposed that these bands are due to the hydrogen bonding of the OH units to the arsenate  
243 units.

244 The Raman spectrum of the Czech dussertite in the region 3300 to 3600  $\text{cm}^{-1}$  is shown  
245 in Fig. 3. Raman bands are observed at 3015, 3242, 3371 and 3452  $\text{cm}^{-1}$ . The first three  
246 bands are assigned to water adsorbed on the surface of the dussertite and/or coordinated water  
247 in the structure of dussertite. The last band at 3452  $\text{cm}^{-1}$  is assigned to the stretching  
248 vibrations of the OH units. In the Raman spectrum of the Algerian dussertite, an intense  
249 Raman band at 3348  $\text{cm}^{-1}$  is observed. Three broad bands for this dussertite sample are  
250 observed at 3023, 3222 and 3371  $\text{cm}^{-1}$ . The observation of Raman (and infrared) bands in the  
251 3015 to 3371  $\text{cm}^{-1}$  shows water is strongly hydrogen bonded. This suggests that water  
252 molecules may be involved in the dussertite structure. The presence of molecular water in the  
253 crystal structure of dussertite is supported by the X-ray single-crystal study of antimonian  
254 dussertite published by Kolitsch *et al.*<sup>1</sup>. The presence of water in the structure may be  
255 necessary for the stability of the mineral.

256  
257 The infrared spectrum of the Czech dussertite in the region 2800 to 3600  $\text{cm}^{-1}$  is  
258 shown in Fig. S3. The infrared band at 3446  $\text{cm}^{-1}$  is ascribed to the OH stretching vibrations  
259 of the hydroxyl units in the dussertite structure. This band is the equivalent of the Raman  
260 band observed at 3452  $\text{cm}^{-1}$ . This band is sharp for bands in this spectral region, whereas  
261 water bands are quite broad. The broad band at 3223  $\text{cm}^{-1}$  is assigned to hydrogen bonded  
262 OH groups and water molecules. Raman spectrum of dussertite in the region of the  $\delta$  ( $\nu_2$ )  
263  $\text{H}_2\text{O}$  bending vibrations does not prove the presence of molecular water. However, in the  
264 infrared spectrum are observed bands at 1634 and probably also 1562  $\text{cm}^{-1}$  which may be  
265 connected with these vibrations. The bands at 1384 and 1347  $\text{cm}^{-1}$  may be related to the  $\delta$   
266 M/OH bending vibrations or overtones and/or combination bands. Raman bands at 1250,  
267 1220, 1176 and 1115 are attributed to the  $\delta$  As-OH and  $\delta$  P-OH bending vibrations and  $\nu_3$   
268  $(\text{PO}_4)^{3-}$  antisymmetric stretching vibrations. Some authors (see the Introduction) assume that  
269 dussertite may contain only hydroxyl ions, but according to other authors dussertite may

270 contain molecular water in its crystal structure, similarly as some other minerals of the  
271 crandallite group. Thus the question of this crystal-coordination of molecular water in the  
272 studied dussertite sample was not resolved on the basis of the Raman spectra but may be  
273 inferred from the infrared spectra studied in this paper.

274

## 275 **CONCLUSIONS**

276

277 The Raman spectrum of dussertite from the Huber stock deposit, Krásno near Horní Slavkov  
278 ore district, the Slavkovský les Mountains, Czech Republic was obtained and the spectrum  
279 compared with the Raman spectrum of dussertite downloaded from the RRUFF web site. The  
280 spectra showed great similarity as might be expected. Raman bands attributable to the  
281 stretching and bending vibrations of the  $(\text{AsO}_4)^{3-}$  and  $(\text{AsO}_3\text{OH})^{2-}$  units are obtained. This  
282 suggests that dussertite contains OH<sup>-</sup> group. The OH contents in dussertite should be  
283 variable. Some bands were assigned to the  $(\text{PO}_4)^{3-}$  and  $(\text{PO}_3\text{OH})^{2-}$  vibrations.

284

285 The Raman spectrum shows a complex set of overlapping bands in the OH stretching region.  
286 Raman bands are observed at 3015, 3242, 3371 and 3452  $\text{cm}^{-1}$ . The first three bands are  
287 assigned to water adsorbed on the surface of the dussertite and/or coordinated water in the  
288 structure of dussertite. The observation of Raman (and infrared) bands in the 3015 to 3371  
289  $\text{cm}^{-1}$  shows water is strongly hydrogen bonded. This suggests that water molecules are  
290 involved in the dussertite structure. The presence of molecular water in the crystal structure  
291 of dussertite is supported by the X-ray single-crystal study of antimonian dussertite published  
292 by Kolitsch *et al.*<sup>1</sup>. The presence of water in the structure may be necessary for the stability  
293 of the mineral. The infrared band of the OH stretching region is well defined. The broad  
294 infrared band of hydrogen bonded molecular water and/or hydroxyls centred upon 3223  $\text{cm}^{-1}$   
295 is observed together with two bands at 1634 and 1562  $\text{cm}^{-1}$ , related to the H<sub>2</sub>O bending  
296 vibrations. This broad band is not observed in the Raman spectrum.

297

## 298 **Acknowledgements**

299

300 The financial and infra-structure support of the Queensland University of Technology  
301 Inorganic Materials Research Program of the School of Physical and Chemical Sciences is  
302 gratefully acknowledged. The Australian Research Council (ARC) is thanked for funding the  
303 instrumentation. This work was financially supported by Ministry of Culture of the Czech

304 Republic (MK00002327201) to Jiří Sejkora and Jakub Plášil and by a long term Research  
305 Plan of the Ministry of Education of the Czech Republic (No. MSM0021620857) to Ivan  
306 Němec. The downloading of the Raman spectra of dussertite from the RRUFF web site is  
307 acknowledged.
