B Output listing ......................................................... 23
1 Introduction

1.1 Overview of ADMB2R

ADMB2R is a collection of AD Model Builder routines for saving complex data structures into a file that can be read in the R statistics environment with a single command.\textsuperscript{1} ADMB2R provides both the means to transfer data structures significantly more complex than simple tables, and an archive mechanism to store data for future reference.

We developed this software because we write and run computationally intensive numerical models in Fortran, C++, and AD Model Builder. We then analyse results with R. We desired to automate data transfer to speed diagnostics during working-group meetings.

We thus developed the ADMB2R interface to write an R data object (of type \texttt{list}) to a plain-text file. The master list can contain any number of matrices, values, dataframes, vectors or lists, all of which can be read into R with a single call to the \texttt{dget} function. This allows easy transfer of structured data from compiled models to R.

Having the capacity to transfer model data, metadata, and results has sharply reduced the time spent on diagnostics, and at the same time, our diagnostic capabilities have improved tremendously. The simplicity of this interface and the capabilities of R have enabled us to automate graph and table creation for formal reports. Finally, the persistent storage in files makes it easier to treat model results in analyses or meta-analyses devised months—or even years—later.

We offer ADMB2R to others in the hope that they will find it useful.

Please note that ADMB2R is considered an experimental product by NOAA and is released to the scientific community for testing and research purposes. Neither the U.S. government nor the authors make any warranty of correct operation.

The X2R interface is available in three forms: for Fortran as For2R, for C/C++ as C2R, and for AD Model Builder as ADMB2R. This guide specifically describes the ADMB2R interface. The other packages, including documentation, are available from the authors or from CRAN.

1.2 The ADMB2R distribution

ADMB2R is intended for use with AD Model Builder (here, ADMB), a commercial modeling package that is a C++ code generator.\textsuperscript{1,2} Therefore, the ADMB2R user must have a license for ADMB and one for a suitable C++ compiler.

The ADMB2R distribution contains the following:

- This guide, file adm2r-guide.pdf.
- The ADMB2R source, file adm2r.cpp.

\textsuperscript{1}Mention of commercial or noncommercial products does not imply endorsement by NOAA, US Department of Commerce, or any other government agency. No such endorsement is made or implied.

\textsuperscript{2}Otter Research Ltd., P.O. Box 2040, Sidney, B.C., V8L 3S3, Canada. \texttt{http://www.otter-rsch.com/}
• A sample template file, `test-admb2r.tpl` set up for ADMB2R and with calls to ADMB2R routines. (This is a modified version of file `catage.tpl` supplied by Otter Research and is used by permission.)

• A data file, `test-admb2r.dat`, needed to run the sample template file.

• A set of sample ADMB2R calls, file `make-Rfile.cxx`. This is incorporated into the sample template file by an `#include` preprocessor directive.

• A copy of the output produced by the sample calls, file `test-admb2r.rdat`.

ADMB2R was written to comply with the ANSI/ISO C++ standard. It has been tested with ADMB version 7.1.1, using the Borland C++ compiler, version 5.5.1.

1.3 R in brief

The R statistics environment (R Development Core Team 2004) is a free, open-source programmable statistics system implemented as a dialect of the S language. R offers modern statistics and excellent graphics, which are controlled from a command line, by programming, or from one of several graphical interfaces. R can be downloaded from the Comprehensive R Archive Network (CRAN) or its mirrors, e.g., from

http://cran.r-project.org/

All CRAN mirrors contain links to the R Project home page and to R documentation (much available for free download) at several levels of complexity. Among commercially available books, an introductory text is provided by Dalgaard (2002). More extensive treatments, still at an introductory level, are given by Maindonald and Braun (2003) and Verzani (2005). Two widely used reference books are Venables and Ripley (2003) and Venables and Ripley (2000).

1.4 Reporting Problems in ADMB2R

The authors will greatly appreciate receiving reports of any bugs found, so that they can be corrected. We will also attempt to include user improvements or extensions. Such information can be sent to Mike.Prager@noaa.gov.

1.5 ADMB2R and FishGraph

The authors have developed a series of R graphics functions that produce typical graphs of fisheries stock-assessment model output. We anticipate making these FishGraph functions available on the CRAN archive in late 2006. Until FishGraph appears on CRAN, working copies are available from the authors upon email request.

The FishGraph functions take an argument that is an R list, making FishGraph highly compatible with X2R. The required structure of that list, described in the FishGraph manual, allows for extensive user expansion or customization.
By using X2R to save model results and FishGraph to generate graphs, it is possible to produce hundreds of diagnostic plots in seconds. The plots are saved automatically as files for use in reports.

FishGraph is not a formal R package, but rather a series of R functions that we use in our work. We offer it to colleagues to use as is or to modify for their own needs.

### 1.6 Data Structures in ADMB2R

Output from ADMB2R is stored as an R list object in a structured ASCII file readable by R with a `dget` function call. An R list is a container object that holds other data items. Each component of a list is named, and subcomponents (e.g., the rows and columns of a contained matrix) may be named as well.

If output from ADMB2R is stored in (for example) a file named `test.rdat`, it can be read into R as a list named `results` with the single R function call

```r
results = dget("test.rdat")
```

Then the resulting R list object will contain the data saved by the ADMB2R calls, along with corresponding object names, metadata, and data structures specified by the user. Much of the usefulness of ADMB2R is that the files it creates may contain complicated data structures, and yet are read with a single statement.

The following data types may be components of the master list:

- **Comment.** A subroutine is provided for writing R comments to the output file.
- **Info list.** This is a specialized list of character strings in name–value pairs. The current date and time are included automatically. The info list is intended for storing metadata such as the analyst’s name, units used in calculations, etc.
- **Vector** of real or integer numbers or character strings. Here, a vector is a series of name–value pairs, intended to represent a collection of values, such as scalars from a model.
- **Matrix.** A two-dimensional array of real or integer values.
- **Data frame.** The R data frame is like the “dataset” of some statistics packages: a set of samples (stored as rows) on different variables (stored as columns). ADMB2R supports giving meaningful column names and, optionally, row names, to data frames.
- **List.** A list may contain any number of other data objects, such as vectors and lists.

Like most statistics software, R supports the concept of missing (unobserved) values in data objects. ADMB2R supports writing missing values to its output file in R-compatible form.
2 Usage considerations

2.1 Writing Objects

Data objects are written by calling ADMB2R routines from the user's ADMB program. Objects may require one, two, or more calls for complete writing. Most objects require a call to initialize the object, additional call(s) to write data, and a call to finish writing the object.

2.2 Precision

Values are output by ADMB2R using the compiler's default precision. (This is likely to be about 6 digits.) Scientific notation is used when needed. When opening the output file, the user can specify that more or less precision be used in data transfer (§5.1).

2.3 Error checking

Basic error checking is provided by C++ compilers. ADMB2R checks for some additional errors. It generates a log file, admb2r.log, that contains any errors encountered at runtime.

Many types of error are unchecked by ADMB2R. For example, it is possible to call ADMB2R routines to create a file that cannot be parsed correctly by R. This might happen if the ADMB call to close an object is missing or if matrix or vector indices are referenced incorrectly.

2.4 Object names

The ADMB2R system does not enforce correct naming of R data objects—this is up to the user! Legal R names may contain upper- and lower-case letters, digits, and the period (dot) character. Names should not begin with digits. R also allows the underscore in names, but we advise against it; in some versions of the S language, the underscore is an assignment operator. In summary, the user is responsible for choosing suitable names for data objects.

2.5 Missing values

Missing values are supported by ADMB2R in several ways. When opening the output file (§5.1), the user can supply a number that represents missing data (e.g., −99999). Data that match that number will be written as missing values (represented NA in R). In writing a vector object, the user can explicitly set a datum missing by omitting its value (§5.4). In writing a data frame object, missing values are inserted automatically when a vector doesn’t span the full length of the data frame. Alternatively, a boolean vector can indicate missing values (§5.6). In writing a matrix, a boolean matrix can indicate missing values (§5.5) as well. Details are given with the call specifications, in the sections indicated.
3 Using ADMB2R with ADMB

3.1 Including the ADMB2R source

To make the ADMB2R functions available, the user must incorporate the ADMB2R source code with an `#include` preprocessor directive in GLOBALS_SECTION of the model. The file `admodel.h`, distributed with ADMB, must be referenced in the same way. It may be necessary to refer to the files by full pathnames unless they are in the same directory as the ADMB program. Here is an example of the added statements under Windows:

```
//******************************************************************************
GLOBALS_SECTION
    #include "c:\admb\include\admodel.h"
    #include "c:\admb2r\admb2r.cpp"
//******************************************************************************
```

3.2 Including calls to ADMB2R functions

Calls to ADMB2R functions are executed during the reporting phase of ADMB execution. It is recommended that users write their ADMB2R code in a separate file (we use files with a `.cxx` extension) and incorporate them with an `#include` preprocessor directive at the bottom of the ADMB template file's REPORT_SECTION. Alternatively, the ADMB2R function calls can be written directly into the REPORT_SECTION. The following section of a template file shows two lines of conventional ADMB output, followed by ADMB2R output:

```
//******************************************************************************
REPORT_SECTION
    ....
    report << "Bmsy " << B_msy_out << endl;
    report << "F/Fmsy " << fullF/F_msy_out << endl;
    ....
    #include "make_Robject.cxx"     // ADMB2R code
//******************************************************************************
```
4 Typical sequence of calls

The following sequence of calls could be used to write a typical (if brief) data object. The example writes a master list containing an info list, a vector with two elements, a matrix, and a list containing a matrix and a vector. For simplicity, calls are shown here without arguments and are indented structurally.

<table>
<thead>
<tr>

</tbody>
</table>
5 Specifications

The following subsections include calling specifications of all functions in ADMB2R, grouped by type of object written. Objects may require several calls for complete writing. Most require a function call to initialize the object, call(s) to write data, and a call to close the object.

A table of arguments is given for each set of functions. Each line in the table includes the argument name; its data type (real, integer, character or logical); whether the argument is required or optional; and its meaning. When calling routines, arguments must be given in the order specified.

Caution: The interpretation of actual arguments in C++ and ADMB2R is based on their sequence in the call. A function call that includes a value for any optional argument must also include all optional arguments that precede it in the call specification.

5.1 Open and close output file

Subroutine open_r_file opens the output file and writes initialization information to it. This also opens the enclosing R list in the file. Subroutine close_r_file finalizes the output data, closes the master list, and closes the file. We recommend writing ADMB2R output files with a consistent file extension, such as .rdat.

```
open_r_file(fname, numdigits, missingval)
...
close_r_file()
```

5.1.1 Table of arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fname</td>
<td>Character</td>
<td>Required</td>
<td>Name of file to open for writing.</td>
</tr>
<tr>
<td>numdigits</td>
<td>Integer</td>
<td>Optional</td>
<td>Digits after the decimal point in transfer of real values. If not given, output uses the compiler's default precision, typically about 6 digits.</td>
</tr>
<tr>
<td>missingval</td>
<td>Real</td>
<td>Optional</td>
<td>Missing value flag. Any datum matching this value (see §5.1.2) will be output as the R missing-value indicator, NA.</td>
</tr>
</tbody>
</table>

See caution box on optional arguments, p. 7.
5.1.2 Missing-value comparisons

Because comparison of floating-point values for equality is unreliable, ADMB2R uses a fuzzy test to decide whether a datum matches the missing-value flag. Let \( d \) be the datum being written and \( m \) the missing-value flag. Then NA is written instead of the datum when \(|m - d| < \varepsilon\). The ADMB2R code declares \( \varepsilon = 10^{-6} \). The user can change the value of \( \varepsilon \) by modifying its declaration in the ADMB2R code.

5.1.3 Example 1

```c
open_r_file("run22.rdat");
...
close_r_file();
```

Example 1 creates an R-compatible output file, run22.rdat. All data are written using default precision. No missing-value flag is specified.

5.1.4 Example 2

```c
open_r_file("run23.rdat", 5, -99999);
...
close_r_file();
```

Example 2 creates output file run23.rdat. Data are written with five digits after the decimal point. Any datum equal to \(-99999\) will be replaced with NA (but see §5.1.2 for details). Because the optional argument for missing-value flag is given, the optional argument for precision is required here.

5.1.5 Example 3

```c
open_r_file(adprogram_name + ".rdat", 12);
...
close_r_file();
```

This code uses the built-in ADMB variable adprogram_name to construct an output file name like that of the ADMB template file, but with .rdat extension. Data values are written with twelve digits after the decimal point. No missing-value flag is specified.

5.1.6 Notes

These two functions must be the first and last calls in the sequence that writes an R object. ADMB2R allows only one file holding an R object to be written at a time. It must be completed and closed before another is written.
5.2 Info list

The info list, meant for metadata, holds a series of name-value pairs as an R list. The date can be inserted automatically as the first list component. At least one additional item is required.

```r
open_r_info_list(name, writestamp)
  wrt_r_item(name, value)
  close_r_info_list()
```

5.2.1 Table of arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>open_r_info_list()</code></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of info list</td>
</tr>
<tr>
<td>writestamp</td>
<td>Boolean</td>
<td>Optional</td>
<td>Flag to write date/time stamp to info list. Default: true</td>
</tr>
<tr>
<td><code>wrt_r_item()</code></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of info item</td>
</tr>
<tr>
<td>value</td>
<td>Character, boolean, integer or double</td>
<td>Optional</td>
<td>Value of info item. If not specified, NA is written.</td>
</tr>
</tbody>
</table>

5.2.2 Example

```r
open_r_info_list("Metadata");
  wrt_r_item("units.length", "mm");
  wrt_r_item("units.mass", "mt");
  wrt_r_item("run.title", title);
  wrt_r_item("finaldraft", false);
  close_r_info_list();
```

The example demonstrates writing an info object to store metadata on an analysis. In the fourth line, the actual argument title is assumed to be a C++ character variable.

Because the call to `open_r_info_list` does not include the optional argument `writestamp`, the name "date" and a character representation of the current date and time form the first pair in the info list. To omit date and time, change the first line of the example to

```r
open_r_info_list("Metadata", false);
```
5.3 Comment object

5.3.1 Summary

For troubleshooting purposes, or whenever the ADMB2R output file will be viewed directly, it can be useful to insert R comments. These are ignored by the R parser, just as they are when entered at the command line.

```r
wrt_r_comment(text)
```

5.3.2 Examples

```r
wrt_r_comment("INFO object follows this comment.")
...
wrt_r_comment("This file written with revised source.")
```

5.3.3 Notes

Because comments are ignored by the R parser, they are not part of the data object once it has been read into R.
5.4 Vector object

5.4.1 Overview

In ADMB2R, a vector object is intended to store an unordered collection of named numeric (real or integer), character, or logical values. As R does not mix data types within a vector, it is best to write a separate vector for each data type.

The design of ADMB2R accommodates ordered sequences (such as time series) as matrices (§5.5) or as columns of a data frame (§5.6). Either of those forms would be a better choice for storing ordered data.

```
open_r_vector(name)
   wrt_r_item(name, value)
   ...
close_r_vector()
```

5.4.2 Table of Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>open_r_vector()</td>
<td></td>
<td></td>
<td>Name of vector</td>
</tr>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of vector element</td>
</tr>
<tr>
<td>value</td>
<td>Character, boolean,</td>
<td>Optional</td>
<td>Value of vector element. If not specified, NA is written.</td>
</tr>
<tr>
<td></td>
<td>integer or double</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5.4.3 Example

```
open_r_vector("parms");
   wrt_r_item("vb.li", linf);
   wrt_r_item("vb.k", vbk);
   wrt_r_item("vb.t0");
   wrt_r_item("MSY", msy);
close_r_vector();
```
5.4.4 Notes

The example shows use of a vector to store four quantities from an analysis in fish population dynamics. The first, second, and fourth elements of the vector are stored from ADMB variables; the third element is set to a missing value.

A single element from an ADMB vector or matrix can be given as the value argument using subscript notation; for example, myvector(3) or mymatrix(2,5).

When using the resulting vector in R, components can be selected with literal subscripting. For example, consider the vector written above and named parms. Once the master object containing this vector has been read into R and named (e.g.) result, the MSY value in the vector can be referenced and assigned to a variable as follows:

```r
localmsy <- result$parms["MSY"]
```
5.5 Matrix object

A matrix in R is a two-dimensional array, with every element having the same data type. This version of ADMB2R can write matrices of real or integer numbers. If the types are mixed, R will interpret the matrix as real.

Matrices may have row or column names, both, or neither. Names can be taken from the indices of the ADMB data matrix, or they can be provided explicitly by a call or calls to wrt_r_namevector before closing the matrix.

```
open_r_matrix(name)
  wrt_r_matrix(xx, rowoption, coloption, isna, na_matrix)
  wrt_r_namevector(rowvec, i_start, i_stop)  // Call type 1
  wrt_r_namevector(start, stop, inc)        // Call type 2
...
close_r_matrix()
```

5.5.1 Arguments of open_r_matrix, wrt_r_matrix

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of matrix.</td>
</tr>
<tr>
<td>xx</td>
<td>Real or integer</td>
<td>Required</td>
<td>ADMB matrix of values.</td>
</tr>
</tbody>
</table>
| rowoption     | Integer         | Optional | Flag to write row names—
|               |                 |          | 0: Omit names (default). 1: Row indices become names. 2: Names supplied in subsequent call to wrt_r_namevector. |
| coloption     | Integer         | Optional | Flag to write column names—
|               |                 |          | 0: Omit names (default). 1: Column indices become names. 2: Names supplied in subsequent call to wrt_r_namevector. |
| isna          | Boolean         | Optional | Signals presence of na_matrix argument. Default: false.                    |
| na_matrix     | Boolean         | Optional | Where true, corresponding element of xx matrix is written as missing (NA). |

* See caution box on optional arguments, p. 7.

When using indices for row or column names, consider that ADMB matrices are not necessarily indexed from 1. For example, a matrix might have rows indexed from 1950 to 2005, designating calendar years of the study.
5.5.2 Arguments of \texttt{wrt\_r\_namevector}

Two types of call to \texttt{wrt\_r\_namevector} are supported. The first type generates dimension names from an \texttt{ADMB} data vector of integers. The second type generates names as a regular sequence of numbers.

**FIRST CALL TYPE**

\begin{verbatim}
\texttt{wrt\_r\_namevector(rowvec, i\_start, i\_stop);}
\end{verbatim}

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowvec</td>
<td>Integer</td>
<td>Required</td>
<td>Vector of values for row or column names.</td>
</tr>
<tr>
<td>i_start</td>
<td>Integer</td>
<td>Optional</td>
<td>First index of rowvec to use.</td>
</tr>
<tr>
<td>i_stop</td>
<td>Integer</td>
<td>Optional</td>
<td>Last index of rowvec to use.</td>
</tr>
</tbody>
</table>

⚠️ See caution box on optional arguments, p. 7.

**SECOND CALL TYPE**

\begin{verbatim}
\texttt{wrt\_r\_namevector(start, stop, inc);}
\end{verbatim}

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>Integer</td>
<td>Required</td>
<td>First number in generated sequence.</td>
</tr>
<tr>
<td>stop</td>
<td>Integer</td>
<td>Required</td>
<td>Last number in generated sequence.</td>
</tr>
<tr>
<td>inc</td>
<td>Integer</td>
<td>Optional</td>
<td>Increment of generated sequence. Default: 1</td>
</tr>
</tbody>
</table>

5.5.3 Example 1

\begin{verbatim}
\texttt{open\_r\_matrix("n.at.age");}
\texttt{wrt\_r\_matrix(naa, 1, 2);}
\texttt{wrt\_r\_namevector(all\_years, 5, 20);}
\texttt{close\_r\_matrix();}
\end{verbatim}

In Example 1, with 1 passed for rowoption, row names are taken from the row indices of the \texttt{ADMB} matrix \texttt{naa}. With 2 passed for coloption, column names are written by the call to \texttt{wrt\_r\_namevector}; they are the 16 elements of the vector \texttt{all\_years} indexed 5 through 20.
In this example, a matrix named \texttt{l.at.age} is written from the ADMB matrix \texttt{laa}. Row names are written as the series, \{9, 12, 15, \ldots, 27\}. No column names are written.

In this example, a matrix named \texttt{l.at.age} is written from the ADMB matrix \texttt{laa}. The actual argument \texttt{true} indicates that an additional, boolean matrix (here named \texttt{na_matrix}) is supplied, in which positions of \texttt{true} values correspond to missing values in \texttt{laa}. Row and column names for \texttt{l.at.age} are derived from the row and column indices of \texttt{laa}.
5.6 Data frame object

5.6.1 Overview

A data frame in R is a collection of columns (data vectors) of equal length; it forms a rectangular structure similar to a matrix. Unlike a matrix, columns may hold differing data types. A data frame typically contains a set of samples (stored as rows) on several variables (stored as columns). ADMB2R can write columns containing real numbers or integers. A data frame is opened with open_r_df, and each column is written in turn with wrt_r_df_col.

Function wrt_r_df_col can be called in two forms, as illustrated here. The first writes a column from an ADMB vector. The second writes a generated integer sequence.

```
open_r_df(name, start, stop, writerow)
  wrt_r_df_col(name, xx, shift, isna, na_vector)
  wrt_r_df_col(name, start, stop, inc, isna, na_vector)
  ...
  wrt_r_namevector(rowvec, i_start, i_stop)  // Call type 1
  wrt_r_namevector(start, stop, inc)        // Call type 2
close_r_df()
```

Row and column names. Each column of a data frame has a name. The rows may have names, which refer to rows across all columns. Row names are written by calling wrt_r_namevector (§5.5.2, §5.6.5) immediately before closing the data frame.

Missing values. Missing values can be written in three different ways. They can be added by the internal coordinate system (described next), by use of the global missing-value indicator (§5.1), or by providing boolean vectors to indicate missing values.

Internal coordinates. When ADMB2R opens a data frame, an internal coordinate system indexing the rows is set up from values passed for arguments start and stop. This coordinate system can be used to provide row names. More importantly, it is compared to the indices of each ADMB vector written as a column; those indices are expected to match the internal system or—if shift is passed—to match it when $(s - 1)$ is added to the vector’s indices, where $s$ is the value of shift. If the vector is shorter than the internal coordinates, ADMB2R pads it with missing values at the start, finish, or both to align its indices with the internal coordinates. When a data frame is closed by ADMB2R, its internal coordinate system ceases to exist.

In understanding the internal coordinate system, remember that ADMB vectors are not necessarily indexed from 1. For example, an analysis covering fifty years might include a variable indexed as cost(1951) through cost(2000). In that case, a data frame might be written using ADMB2R with 1951 passed for start and 2000 passed for stop. A second variable, observed for only part of the study, might be indexed as price(1962) through price(2000). When written as a dataframe column, price would be positioned by aligning its indices with the internal coordinate system, and missing values would be assigned at its beginning.
### 5.6.2 Arguments of open_r_df

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of data frame</td>
</tr>
<tr>
<td>start</td>
<td>Integer</td>
<td>Required</td>
<td>First value of the data frame coordinate system (internal to ADMB2R)</td>
</tr>
<tr>
<td>stop</td>
<td>Integer</td>
<td>Required</td>
<td>Last value of the data frame coordinate system</td>
</tr>
<tr>
<td>writerow</td>
<td>Integer</td>
<td>Optional</td>
<td>Integer flag to write data frame row names— 0: No row names (default). 1: Generated sequence from start to stop by 1. 2: Names provided by subsequent call to wrt_r_namevector.</td>
</tr>
</tbody>
</table>

### 5.6.3 Arguments of wrt_r_df_col(name, xx, shift, isna, na_vector)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of column.</td>
</tr>
<tr>
<td>xx</td>
<td>Integer, real</td>
<td>Optional</td>
<td>ADMB data vector to be written.</td>
</tr>
<tr>
<td>shift</td>
<td>Integer</td>
<td>Optional</td>
<td>If given, (shift-1) is added to the vector's indices before aligning them with data frame's coordinate system. May be positive or negative.</td>
</tr>
<tr>
<td>isna</td>
<td>Boolean</td>
<td>Optional</td>
<td>Must be true if na_vector is supplied.</td>
</tr>
<tr>
<td>na_vector</td>
<td>Boolean</td>
<td>Optional</td>
<td>Vector of same length as xx. Where true, corresponding data element will be NA.</td>
</tr>
</tbody>
</table>

* See caution box on optional arguments, p. 7.

### 5.6.4 Arguments of wrt_r_df_col(name, start, stop, inc, isna, na_vector)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Character</td>
<td>Required</td>
<td>Name of column.</td>
</tr>
<tr>
<td>start</td>
<td>Integer</td>
<td>Optional</td>
<td>Starting value of generated sequence.</td>
</tr>
<tr>
<td>stop</td>
<td>Integer</td>
<td>Optional</td>
<td>Ending value of generated sequence.</td>
</tr>
<tr>
<td>inc</td>
<td>Integer</td>
<td>Optional</td>
<td>Increment value of generated sequence.</td>
</tr>
<tr>
<td>isna</td>
<td>Boolean</td>
<td>Optional</td>
<td>Must be true if na_vector is supplied.</td>
</tr>
<tr>
<td>na_vector</td>
<td>Boolean</td>
<td>Optional</td>
<td>Vector of same length as xx. Where true, corresponding data element will be NA.</td>
</tr>
</tbody>
</table>

* See caution box on optional arguments, p. 7.
5.6.5 Example of writing data frame

```c
firstyear = 1951;
lastyear = 1990;
...
open_r_df("timeseries", firstyear, lastyear, 2);
wrt_r_df_col("year", yr, firstyear);
wrt_r_df_col("yearx", firstyear, lastyear);
wrt_r_df_col("biomass", b, 0, true, na_vector);
wrt_r_df_col("cpue.obsd", u_obsd);
wrt_r_df_col("cpue.pred", u_pred);
wrt_r_namevector(rownums);
close_r_df();
```

In the example, we write a data frame named `timeseries`, whose full range of years is 1951–1990. The ADMB variables used are as follows—

- `firstyear` and `lastyear` are scalar variables.
- `yr` is an ADMB vector indexed from 1 to 40.
- `b` is an ADMB vector indexed from 1951 to 1990, with missing values for `b(1983)` through `b(1985)`.
- `na_vector` is a vector of the same size and indexed the same as `b`. All its values are `false`, except for the three years in which `b` has missing values, which are `true`.
- `u_obsd` is a vector of observed CPUE values, indexed from 1971 to 1990.
- `u_pred` is a vector of predicted CPUE values, indexed from 1951 to 1990.

Explanation of the example, by line number—

1–2. `firstyear` and `lastyear` are assigned values.
4. The data frame is opened, with internal coordinate system running from 1951 to 1990. An eventual call to `wrt_r_namevector` is indicated.
5. Vector `yr` is written as a column named `year`. It is shifted so that its first element aligns with the first row of the data frame.
6. Column `yearx` is written as a sequence of integers, 1951 to 1990.
7. Vector `b` is written as column `biomass`. Boolean vector `na_vector` is passed to mark the missing values in `biomass`.
8. Vector `u_obsd` is written as column `cpue.obsd`. It is padded with 20 missing values at the start.
9. Vector `u_pred` is written as column `cpue.pred`.
10. Row names are written from ADMB integer vector `rownums`.
11. The data frame is closed.
5.7 List object

A list in R is a collection of other data objects, for example, of vectors, matrices, data frames, model results (not supported in ADMB2R), or other lists. Each component of a list has a unique name.

In this version of ADMB2R, a list may contain vectors, matrices, data frames, info objects, and other lists.

```
open_r_list(name)
...
close_r_list()
```

The single argument name is a quoted character string.

Between opening and closing a list, the user should open and write the components of (data objects contained by) the list.

5.7.1 Example

```
open_r_list("laa.matrices");
open_r_matrix("laa.obsd");
  wrt_r_matrix(laa_o);
  close_r_matrix();
open_r_matrix("laa.pred");
  wrt_r_matrix(laa_p);
  close_r_matrix();
close_r_list();
```

The example shows the use of a list to store two matrices. The matrices need not be of the same shape or size.
6 Acknowledgments

The authors are grateful for the support of the U.S. National Marine Fisheries Service, NOAA, during development of this software. In particular, support was provided by the NMFS Southeast Fisheries Science Center, NMFS Northeast Fisheries Science Center, and NMRS National Fisheries Toolbox program. K. W. Shertzer and E. H. Williams helped us test and refine ADMB2R; R. Cheshire and C. Krouse read drafts of the three X2R manuals; and D. Fournier helped us better understand his AD Model Builder software. Among other compilers, the GNU C++ compiler gcc and the open-source Fortran 95 compiler g95 (due to A. Vaught) were used in testing. We thank the authors of those tools for their many efforts. Finally, we thank R. Gentleman, R. Ihaka, and the R Core Team, for without them, R would not exist.

Bibliography

Appendix A  Listing of example file make-Rfile.cxx

The sample file, when incorporated into a suitable AD Model Builder program, generates an output file readable with R. It demonstrates most of the features described in the guide.

```c++
// Example file to create a R object from AD Model Builder
// Open the file using the default AD Model Builder file name, and
// 6 digits of precision
open_r_file(adprogram_name + ".rdat", 6, -999);

// Example of an INFO object
open_r_info_list("Metadata", true);
  wrt_r_item("title", "Sample Catch at Age Model");
  wrt_r_item("species", "Flack Lake Trout");
  wrt_r_item("units.len", "mm");
close_r_info_list();

// Example of a VECTOR object
open_r_vector("parms");
  wrt_r_item("M", M);
  wrt_r_item("avg_F", avg_F);
  wrt_r_item("pred_B", pred_B);
  wrt_r_item("log_q", log_q);
  wrt_r_item("log_popscale", log_popscale);
  wrt_r_item("Obj.fcn", f);
close_r_vector();

// Example of a MATRIX object with no row or column names
open_r_matrix("F.at.age");
  wrt_r_matrix(F);
close_r_matrix();

// Example of a MATRIX object with row names, but no column names;
// rows specified by constructing a series since a vector of years
// is not a variable
open_r_matrix("N.at.age.1");
  wrt_r_matrix(N, 2);
  wrt_r_namevector(1968, 1979);
close_r_matrix();

// Example of the same matrix as above object with row and column names;
// rows specified by constructing a series since the a vector of years
// is not a variable; columns specified by constructing a series since
// a vector of ages isn't supplied
open_r_matrix("N.at.age.2");
  wrt_r_matrix(N, 2, 2);
  wrt_r_namevector(1968, 1979);
  wrt_r_namevector(3, 9);
close_r_matrix();

// Example of a DATA FRAME object composed of two items.
// The data frame will span 1 to the number of ages. The vectors
// span 2 to the number of ages, so NAs will be written for the first
// data point in the two vectors. The row names will be included,
// similar to the matrix object just before this one.
open_r_df("aseries", 1, nages, 2);
```

21
wrt_r_df_col("N.pred", predicted_N);
wrt_r_df_col("N.ratio", ratio_N);
wrt_r_namevector(3, 9);
close_r_df();

// Example of a LIST object
open_r_list("C.at.age.mats");

// matrix with row and column names
open_r_matrix("Est");
  wrt_r_matrix(C, 1, 1);
close_r_matrix();

// another matrix with row and column names
open_r_matrix("Obs");
  wrt_r_matrix(obs_catch_at_age, 1, 1);
close_r_matrix();
close_r_list();
wrt_r_comment("Begin testing permutations of matrix calls unused above");
wrt_r_comment("No rownames; col names from matrix");
open_r_matrix("Obs_catch_at_age");
  wrt_r_matrix(obs_catch_at_age,0,1);
close_r_matrix();
wrt_r_comment("No names, NA matrix");

for( i = 1; i <= nyrs; i++) {
  for(int j = 1; j<= nages; j++){
    NA[i][j] = 0;
  }
}
NA[1][1] = 1;
NA[2][2] = 1;
NA[nyrs-1][nages-1] = 1;
NA[nyrs][nages] = 1;
open_r_matrix("Obs_catch_at_age");
  wrt_r_matrix(obs_catch_at_age,0,0,1,NA);
close_r_matrix();
testcol = column(obs_catch_at_age, 1);
wrt_r_comment("DF column from series");
wrt_r_comment("Then obs_catch 1,3:6 shifted by one.");
open_r_df("Series", 1966, 1970, 2);
  wrt_r_df_col("First", 5,10);
  wrt_r_df_col("Second", testcol(6,10), 1967);
  wrt_r_namevector(1,5);
close_r_df();

// close file
close_r_file();
Appendix B  Listing of resulting R-compatible file test-admb2r.rdat

This example shows the data transferred by running the ADMB2R calls in Appendix A and reading the resulting file into R.

```r
> x=dget("C:/tmp/catage.rdat")
> x
