o. Univ.-Prof. Dr. Wolfgang Lindner, Dr. Michal Kohout

Danksagung

Ich möchte mich an dieser Stelle ganz herzlich bei Herrn Prof. Dr. Wolfgang Lindner für die Möglichkeit bedanken, meine Masterarbeit in der Arbeitsgruppe für Hochleistungstrenntechniken und Materialien gemacht haben zu können. Mein Dank gilt auch der motivierenden Betreuung und Unterstützung während der ganzen Zeit der Masterarbeit. Die interessanten Diskussionen über Honigbienen und Fussball sollen hierbei natürlich nicht unerwähnt bleiben.

Ein weiteres großes Dankeschön gilt meinem Betreuer Michal Kohout, der mir bei jeder Fragestellung immer und überall zur Seite gestanden ist. Dank deiner hervorragenden Betreuung und hilfsbereiten Unterstützung im Labor hatte ich immer Freude am Arbeiten. Für das Korrekturlesen der vorliegenden Arbeit möchte ich dir ebenfalls danken.

Peter Frühauf danke ich speziell für das Packen der Säulen, den zahlreichen Hilfestellungen in Zusammenhang mit der Infinity und der Unterstützung bei vielen anderen Fragen.

Des Weiteren möchte ich mich von ganzem Herzen bei meiner Freundin Pálma bedanken. Ohne deinen Rückhalt wäre ich mit dem Studium sicher noch nicht fertig. Ich möchte dir auch für dein Verständnis und die Hilfsbereitschaft danken. Du hast immer ein offenes Ohr für mich gehabt und dafür möchte ich dir wirklich aufrichtig Danke sagen!

Ich möchte vor allem meinem Kumpel, Nachbar und „Laborabschnittspartner“ Roli danken, mit dem ich nicht nur den Großteil des Masterstudiums, sondern auch die gesamte Masterarbeit absolviert habe. Ich wünsche dir für die anstehende Dissertation alles Gute und viel Erfolg!

Weiters möchte ich mich bei Jano und Vebi bedanken, die immer für einen sehr abwechslungsreichen Alltag gesorgt haben.

Ein besonderes Dankeschön geht an meine Eltern für die Unterstützung während meiner ganzen Studienzeit. Ohne euch wäre mir das Studium nicht möglich gewesen. Danke sagen möchte ich auch meinen Studienkollegen, Schulkollegen und Freunden, meinen beiden Brüdern Tobias und Peter und Allen, die in den letzten Jahren für eine abwechslungsreiche und schöne Zeit gesorgt haben.

I. Aims

The first aim of the present master thesis is the synthesis of a series of novel chiral stationary phases (CSPs) for high performance liquid chromatography (HPLC). In particular the focus is placed on weak anion exchange (WAX) type CSPs. Therefore two different types of linkers (one allylated and one propargylated), which are supposed to serve as immobilization anchor onto preactivated silica, should be synthesized. These linkers should be connected to two basic modules derived from cinchona alkaloids, namely dihydroquinine and dihydroquinidine, via carbamoyl bond with the secondary hydroxylic group. We assume that these reactions would lead to four different selectors, from which a series of CSPs should be prepared.

The second aim is the subsequent evaluation of the synthesized CSPs in terms of their chiral separation ability towards chiral acidic compounds, in particular *N*-protected amino acids, *N*-protected aminosulfonic acids, *N*-protected aminophosphonates and carboxylic acids. A small set of basic and zwitterionic compounds serves as a proof of principle to ascertain an anion exchange mechanism.

Moreover, the influence of different immobilization strategies, endcapping as well as immobilization controllability should be evaluated. Assuming controlled loading of the selectors, we aim to evaluate the influence of the selector density on the silica surface on the overall performance of the new CSPs. Subsequently, the column with the best enantioseparation capabilities should be compared to commercially available chiral anion exchangers.

1. Introduction

The separation of chiral compounds into single enantiomers is an important aspect of analytical and preparative issues including the enantioseparation of chiral drugs [1-6], purity determination of pharmaceutical products [7-11], drug development [12, 13], separation of chiral synthons [14] or bioactive compounds [15-17] and in the flavor and fragrance field [18, 19]. The chiral separation is also required for the analysis of food contaminants [20] and environmental pollutants [21-23]. Nowadays, all pharmacokinetic profiles of optically active drugs need to be determined stereoselectively [14].

Besides liquid chromatography, various methods such as capillary electrophoresis (CE) [11], supercritical fluid chromatography (SFC) [14], gas chromatography (GC) [24], simulated moving bed technology (SMB) [25], enzymatic resolution [26] and crystallization [27] are used to separate enantiomers either on analytical or preparative scale.

1.1. Principles of Chirality

The term chirality is derived from the Greek word *χειρ* (hand) and means handedness. Chiral molecules do have the same atomic composition, they are structural isomers, which have the same constitution, but are not superimposable. Stereoisomers can be classified into diastereomers and enantiomers. Both differ in terms of symmetry and energy level. Diastereomers possess no mirror images in terms of symmetry and they have distinct energy content. Enantiomers are structurally non-superimposable mirror images with identical level of energy. A left and a right hand represent an ideal model of enantiomers. Chiral molecules contain no rotation-reflection axis, mirror plane or a center of inversion [14, 28].

We cannot distinguish enantiomers in an achiral environment. They have the same physical properties (e.g. melting point) except for the behavior towards polarized light, which in turn represents a chiral environment. A 1:1 molar mixture of two enantiomers is called racemate or racemic mixture. The overall optical rotation for a racemic mixture is zero because both of the enantiomers are optical isomers with exactly opposite rotation of polarized light [14, 29].

Chirality is grounded in various chiral elements [14, 30]:

- center of chirality (e.g. tetra-coordinated carbon with four different substituents)
- chiral axes (e.g. ortho-substituted biphenyls)
- chiral planes (e.g. substituted paracyclophanes)
- chiral helices (e.g. deoxyribonucleic acid - DNA)
- topologically chiral elements (e.g. iron-sulfur proteins [31])

Chiral molecules do have a key role in living systems. Almost all natural strains of amino acids and sugar molecules consist of only one enantiomer. Naturally occurring proteinogenic amino acids largely consist of the (*S*)-form, while the majority of sugar molecules found in living organisms have the (*R*)-form. Since amino acids are building components for proteins and sugars are building blocks of polysaccharides like cellulose (helical structure) or starch, chirality can be found throughout all living systems [32, 33].

Figure 1.1.: The two stereoisomers of limonene; left hand side: (*R*)-limonene, right hand side: (*S*)-limonene.

Due to the chiral nature of all living systems exogenic chiral compounds like food additives (e.g. flavors) and drugs are recognized by sensory organs and metabolized by enzymes stereoselectively. One renowned example for the different recognition of enantiomers by sensory organs is limonene. In **figure 1.1.** the structures of the two enantiomers are given. The (*R*)-enantiomer has a fragrant smell of orange, the (*S*)-enantiomer of this flavor has turpentine odour [14].

Another prominent examples for the different effect of enantiomers in terms of pharmaceutical responses are levopropoxyphen and dextropropoxyphene. The first mentioned (*2R,3S*)-levopropoxyphene has antitussive activity, whereas the

(2*S*,3*R*)-enantiomer dextropropoxyphene is an analgesic agent. Due to the different medical effects of enantiomers it is of utmost importance to administer the right stereoisomer [14].

The drug Contergan[®] is probably the most famous and tragic example for the importance of chirality in terms of drug effects. The active substance thalidomide (the structure is depicted in **figure 1.2.**) exists in two enantiomeric forms. Thalidomide was prescribed in the late 1950s as a sedative with anti-nausea effect for treating insomnia and morning sickness of pregnant women. In those days thalidomide was administered as racemic mixture. The drug was withdrawn in 1961 due to the terrible teratogenic effect [34]. In later investigations it could be shown that only the (*R*)-enantiomer shows beneficial effects (so-called eutomer) and the (*S*)-enantiomer (so called isomeric ballast or distomer [26]) is responsible for the teratogenic behavior. However, the administration of the single (*R*)-enantiomer would not contribute to a less teratogenic effect because thalidomide shows rapid *in vivo* chiral inversion and therefore racemization [35].

Figure 1.2.: Structure of thalidomide.

1.2. Separation of Enantiomers

As already mentioned above enantiomers do have identical physical and chemical properties [30] except their exactly opposite behavior towards polarized light. In an achiral environment one cannot distinguish between enantiomers or separate them from each other. Basically there are two main strategies for separating enantiomers. Both deal with the general approach of forming diastereomers, either via covalent bonding or formation of labile diastereomeric associates. **Figure 1.3.** illustrates these two basic concepts.

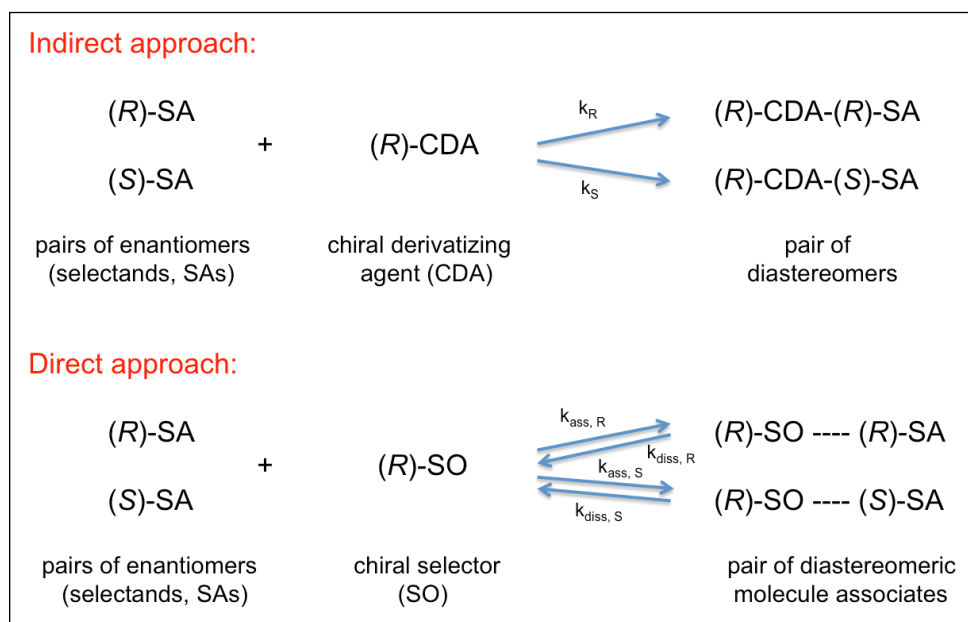

Figure 1.3.: The two basic concepts of enantioseparation; adapted and modified from [14].

In the indirect approach a pair of chemically stable diastereomers with an enantiomerically pure auxiliary, a chiral derivatizing agent (CDA), is formed. This reaction must proceed quantitatively. Since a covalent bond between selectand (SA) and CDA is formed, the separated diastereomers must be cleaved after separation to give an enantiomerically pure product. This is one drawback of the indirect method. Of course no racemization of the starting compounds and no kinetic racemate resolution must happen. For the separation no chiral environment and separation system is necessary because diastereomers differ in their physicochemical properties. Therefore reversed phase (RP) or normal phase (NP) chromatography is often sufficient for the separation of organic molecules [14, 30, 36].

The direct approach is based on the formation of a diastereomeric pair of molecule associates. This formation must be reversible (non-covalent binding). Two enantiomeric SAs interact with the enantiomerically pure chiral selector (SO), which is e.g. immobilized on a silica surface for chiral stationary phase (CSP) mode in an HPLC separation system. If the binding strength differs for both of the SAs (due to differences in energy content and therefore unequal thermodynamic complex stabilities and equilibrium constants) they are separable due to different retention. Another experimental mode for the direct approach would be the chiral additive mobile phase mode, which is of little importance nowadays [14, 30].

The interaction of SA with SO in the direct approach for the separation of enantiomers can be explained by thermodynamic considerations (*van't Hoff* analysis) and a basic interaction model called three-point attachment [37].

1.3. Three-point Interaction Model

This model was proposed in 1952 by K. Dalglish [14, 38]. Although this model is not free of criticism and its validity is still under debate (e.g. a four-location model was proposed by Mesecar and Koshland in 2000 for describing the enantiodiscrimination ability of proteins and enzymes [39]), it visualizes the direct approach of enantioseparation using liquid chromatography and chiral stationary phases.

In **figure 1.4.** the three-point interaction model is illustrated. An enantiomerically pure selector (SO) is immobilized on a silica surface representing a chiral stationary phase. This selector contains three theoretical interaction sides (A, B and C), which can interact with a potential chiral selectand via three binding sites (SA; a, b and c). These non-covalent interactions and bonds can be of electrostatic nature like ionic interaction, Van der Waals forces like dipole-dipole, dipole-induced dipole and ion-dipole interactions and/or hydrogen bonding, π - π -interactions, hydrophobic interactions and a steric influence as well. The interaction must not be of attractive nature; repulsive interaction can also be involved in the three-point interaction [40].

In case of an “ideal fit” all three interactions are complementary and match perfectly. One example for a complementary interaction would be e.g. an interaction between a hydrogen donating amino group of a SO and a hydrogen accepting carbonyl group of a SA. The “ideal fit” situation results in strong non-covalent bonding of SO and SA, and therefore high retention for the (*S*)-SA in the case shown below.

A “non-ideal fit” situation results in for example just one complementary interaction and therefore the interaction strength is weaker in comparison to the “ideal fit”. Therefore the (*R*)-SA is lower retained and elutes before the (*S*)-SA.

This result is also indicated by a lower association constant ($K_S > K_R$). Due to the resulting difference in retention times enantioseparation can be observed [14, 41].

Figure 1.4.: Visualization of the three-point interaction model; adapted and modified from [40].

1.4. Thermodynamic Aspects of Enantioseparation

Enantioseparation is of course influenced by temperature. All chromatographic parameters like column efficiency, resolution, enantioselectivity and retention are influenced by changes in temperature. Thermodynamic considerations can be applied for the reversible formation of a SO--SA complex both for the (*R*)-SA and the (*S*)-SA. Different affinities of enantiomeric SAs to a chiral SO are described by changes of the Gibbs free energy $\Delta G^0_{(R)}$ and $\Delta G^0_{(S)}$ in the free and complexed form. The equilibrium processes can be described with the equilibrium binding constant K_i according to **equation [1.1]** (subscript *i* denotes the respective enantiomer), which combines the difference in free energy $\Delta G^0_{(i)}$ and K_i , wherein R is the universal gas constant (8.314 J.K⁻¹.mol⁻¹) and T the absolute temperature in Kelvin:

$$\Delta G_i^0 = -RT \cdot \ln K_i \quad [1.1]$$

The Gibbs free energy consists of an enthalpic ($\Delta H_{(i)}$) and entropic part ($\Delta S_{(i)}$). This fact is represented by the *Gibbs-Helmholtz equation* (see **equation [1.2]**):

$$\Delta G_i^o = \Delta H_i^o - T\Delta S_i^o \quad [1.2]$$

A simple combination of **equation [1.1]** and **[1.2]** results in the *van't Hoff equation*, which is depicted in **equation [1.3]**:

$$\ln K_i = -\frac{1}{T} \frac{\Delta H_i^o}{R} + \frac{\Delta S_i^o}{R} \quad [1.3]$$

This linear equation can be used for *van't Hoff* thermodynamic analysis by simply plotting $\ln K_i$ vs. $1/T$. The intercept reflects the change of entropy $\Delta S_{(i)}^o$, whereas the slope represents the change of enthalpy $\Delta H_{(i)}^o$. The enantioselectivity α , which is the quotient between the retention factors k_i of one pair of enantiomers (see **equation [3.2]** in **chapter 3.4.** and **equation [1.6]**), is described as the difference between Gibbs free energy changes upon interaction of one SA with the SO over the other SO-SA associate. Under the assumption that $K_S > K_R$ (retention for the (S)-enantiomer is higher) one can deduce **equation [1.4]**:

$$\Delta\Delta G_{S,R}^o = \Delta G_S^o - \Delta G_R^o = -RT \cdot \ln \frac{K_S}{K_R} = -RT \cdot \ln \alpha \quad [1.4]$$

This equation can again be combined with the *Gibbs-Helmholtz* relationship, which results in **equation [1.5]**:

$$\ln \alpha = -\frac{1}{T} \frac{\Delta\Delta H_{(i)}^o}{R} + \frac{\Delta\Delta S_{(i)}^o}{R} \quad [1.5]$$

The expression above links the experimentally determinable enantioselectivity coefficient α and the absolute temperature with the differential enthalpy $\Delta\Delta H_{(i)}^o$ and entropy $\Delta\Delta S_{(i)}^o$ of enantioseparation. Note that the enantioselectivity coefficient α depends on two chromatographic parameters - the retention factor k_i and the phase ratio Φ (quotient between the volume of the stationary and the mobile phase) - as presented in **equation [1.6]**:

$$\alpha = \frac{k_S}{k_R} = \frac{K_S \cdot \Phi}{K_R \cdot \Phi} \quad [1.6]$$

Based on experimental results one can assume that enantioseparation processes are usually controlled by enthalpic contributions [40, 42, 43].

1.5. Chiral Stationary Phases

For a successful separation of enantiomers two major parameters are important. The first is the selection of an appropriate chiral stationary phase (CSP), which is able to separate the selected compounds. The second important parameter is the choice of the mobile phase conditions to yield retention and separation. In this chapter the main groups of CSPs and chiral selectors (SOs), respectively, are briefly described.

In principal one can distinguish between three different types of CSPs:

- Brush type: The chiral selector is immobilized via a spacer on an organic or inorganic support like silica. For chiral anion exchange purposes the most common type is the brush type CSP.
- Organic polymer type: Either the pure crosslinked chiral polymer serves as CSP or an organic polymer is coated onto the surface of a support material. Grafted polymers on a support material are also possible.
- Molecular imprinted polymer type: In this case either the pure polymer itself is imprinted and serves as CSP or the imprinted polymer is surface-grafted onto silica [14].

The chiral selectors can be grouped into low-molecular mass selectors, macrocyclic and macromolecular selectors.

An overview of these chiral selectors is depicted in **figure 1.5.**, for a more detailed description also with respect to advantages and disadvantages of every single CSP and selector type see [14, 40, 41]. Hereafter only the chiral anion exchange type is discussed in a more detailed view because the aim of the thesis was the synthesis and evaluation of weak anion exchange (WAX) type CSPs for liquid chromatography.

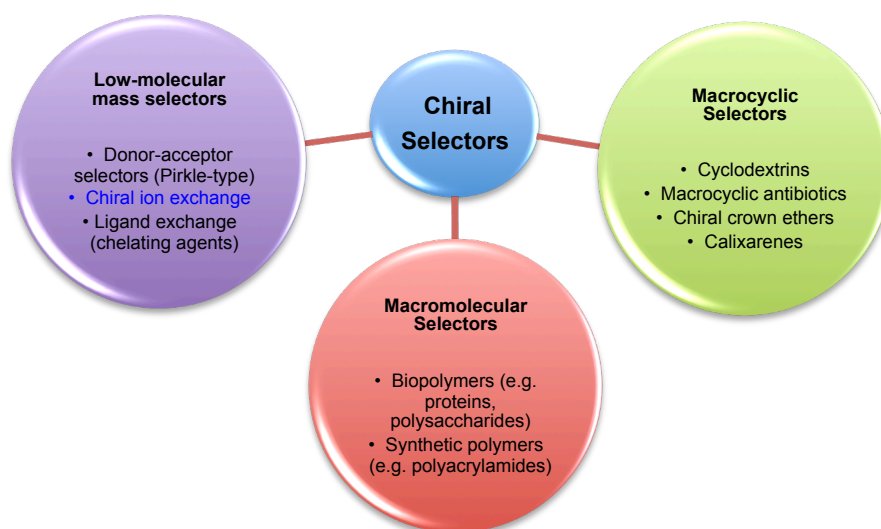

Figure 1.5.: Overview of the different types of chiral selectors; data collected from [14].

1.6. Chiral Ion Exchange

In the field of chiral ion exchangers one can distinguish between anion, cation and zwitterionic type CSPs. All three types were developed, among others, in our working group.

1.6.1. Cation Exchange type CSPs

For a chiral cation exchange stationary phase a chiral acidic SO has to be immobilized on a silica surface. Acidic compounds, which are suitable for cation exchange, are e.g. carboxylic acids used as weak cation exchangers (WCXs). Strong cation exchangers (SCXs) can be based e.g. on sulfonic acids. Other possibilities would be the use of sulfinic, phosphoric, phosphonic or phosphinic acids. Hoffmann and Lindner have recently developed a novel type of SCX-CSPs [44]. They immobilized a SO based on a chiral 2-aminocyclohexanesulfonic acid (ACHSA) derivative and were able to separate basic compounds (chiral organic amines) such as common drugs like bupranolol, clenbuterol, quinine, terbutalin and others under a polar organic mobile phase condition. The structure of one SCX-CSP is shown in **figure 1.6.** with (1*R*,2*R*) configuration of the ACHSA residue.

This selector contains two chiral centers in position 1 and 2. The same selector with just opposite configuration (1*S*,2*S*) was as well synthesized and immobilized on silica by Hoffmann et al. [44] and successfully employed as CSP. Between these two CSPs it was possible to achieve reversal of the elution order due to enantiomeric behavior of the two selectors.

Figure 1.6.: Structure of the SCX-CSP; adapted and modified from [44].

Under basic mobile phase conditions (e.g. addition of diethylamine DEA or diisopropylethylamine DIPEA as a buffer component) the selector is deprotonated and therefore cation exchange as a primary retention effect is possible. Further on hydrogen bonding via the amide -NH as donor and the amide carbonyl as acceptor is possible. The π -acidic dichloro-substituted aromatic moiety is capable of π - π -interactions.

1.6.2. Zwitterion type CSPs

This type of CSPs contains both anion exchange type structural motifs as well as cation exchange type motifs. The fusion of them results in zwitterionic exchange type (ZWIX) CSPs, which were recently developed by Hoffmann et al. [33, 45] in our working group. A big advantage of this type of CSPs is the broad applicability in terms of separable compounds. Both anions as well as cations can be separated. The list can further be extended to zwitterionic SAs such as proteinogenic amino acids, drugs like DOPA (3,4-dihydroxyphenylalanine) and aminosulfonic acids (e.g. ACHSA).

In **figure 1.7.** the structure of a selected ZWIX-CSP invented by Hoffmann et al. in 2008 [45] is shown. It is a synthetic combination of quinine-type WAX (red colored) and ACHSA-type SCX (blue colored).

The selector itself is a zwitterion in protonated form of the quinuclidine ring of the quinine moiety and deprotonated form of the sulfonic group at the ACHSA moiety.

Figure 1.7.: ZWIX-CSP developed by Hoffmann et al. 2008; adapted and modified from [45].

The charge state is dependent on the mobile phase conditions. During retention one charged moiety can act as an intramolecular counterion and therefore the concentration of buffer salts in the mobile phase can be reduced [46].

In the case of the ZWIX-CSP shown in **figure 1.7.** various interactions with a potential chiral analyte are possible. Primary ionic interaction due to the charged quinuclidine ring and the sulfonic acid group of the ACHSA residue, hydrogen bonding via the carbonyl and -NH of the carbamate bridge, π - π -interaction because of the aromatic quinoline ring and a sterical influence as well. The overall interaction results in a potential ability for chiral recognition and therefore enantioseparation.

1.6.3. Anion Exchange type CSPs

Because of a broad range of chiral acidic compounds used e.g. as drugs or agrochemicals (see above) separation of these compounds and analysis of the enantiomeric ratio is an important task in analytical chemistry. The enantioseparation is possible via anion exchange type CSPs with immobilized selectors containing ionizable primary, secondary, tertiary or constantly charged quaternary amines, whereas quaternary amines represent the strongest anion exchange type SOs.

One important group of weak anion exchangers (WAXs), namely *O*9-*tert*-butyl carbamate derivatives of the cinchona alkaloids quinine and quinidine, were invented by Lindner and Lämmerhofer and have been commercialized under the trade name

CHIRALPAK[®] QN-AX and QD-AX by Chiral Technologies [13]. In **figure 1.8.** the structures of these two CSPs are shown.

Figure 1.8.: Structures of CHIRALPAK[®] QN-AX and QD-AX CSPs; adapted and modified from [47, 48].

With this type of CSP various interactions are possible which are discussed below (see **chapter 1.7.**). Primary ionic interaction takes place via the protonated tertiary amine in the quinuclidine ring under acidic mobile phase conditions. The only conformational difference between QN-AX and QD-AX are the centers of chirality in position 8 and 9. QN-AX possesses (8*S*,9*R*) whereas the pseudoenantiomeric QD-AX [13] has (8*R*,9*S*) configuration. All the other centers of chirality (located at the quinuclidine ring, position 1 = chiral tertiary amine) are of the same absolute configuration (1*S*,3*R*,4*S*).

The selectors in case of QN-AX and QD-AX are immobilized via the vinyl group (positions C10, C11) of the quinuclidine ring. One advantage of the naturally occurring and relatively cheap quinine (QN) and quinidine (QD) is that immobilization is possible without further derivatization. The immobilization is carried out with radical thiol-ene addition onto mercaptopropyl-modified silica.

In former studies, native QN and other cinchona alkaloids have been used as chiral selectors with rather inadequate performance [13]. Therefore the secondary alcohol group of cinchona alkaloids at position 9 was derivatized with a vast number of functional groups resulting in the formation of ethers, amides, esters, sulfonamides and hydrazine derivatives. All these selectors were evaluated in terms of their applicability for chiral separations, but the carbamate derivatives, especially *t*Butyl carbamate of QN and QD, provided high enantioselectivities for a broad range of selectands including *N*-protected amino acids, *N*-protected aminosulfonic acids, *N*-protected aminophosphonates and carboxylic acids (see **chapter 3**) [13].

1.7. Retention Mechanism for *N*-protected amino acids

A retention mechanism for chiral acidic analytes can be explained on the basis of a strongly retained compound. As a model CSP in former studies commercially available Chiralpak® QN-AX *t*-Butyl carbamoylated quinine (the structure is given in **figure 1.8.** above) has been used. This CSP demonstrates extraordinary high enantioselectivities, e.g. for *N*-3,5-dinitrobenzoylated (DNB) amino acids like DNB-Leu ($\alpha > 15$ [13]). In this case the (*S*)-enantiomer of DNB-Leu shows much higher retention compared to the respective (*R*)-enantiomer.

Due to the very strong interaction between stationary phase and the above-mentioned (*S*)-compound it was possible to elucidate a tentative chiral molecular recognition mechanism via a multidisciplinary approach using complementary methods like X-ray crystal structure analysis of co-crystallized selector and enantiomerically pure DNB-(*S*)-Leu, molecular modeling approaches, density functional theory calculations, FTIR, ¹H-NMR, VCD, CD, UV spectroscopy and thermodynamic studies [13].

The primary driving force for retention is the formation of an ion-pair at the quinuclidine ring of the selector. Therefore the bicyclic tertiary amine ring has to be positively charged due to protonation under slightly acidic mobile phase conditions and the associated SA must be simultaneously deprotonated and therefore negatively charged under the same conditions. The protonated amine is then capable of forming non-directed, strong and long ranged Coulomb attraction with the SA. This ion pairing mechanism is the dominating factor for retention.

Besides this primary attraction various intermolecular interactions (all of them of non-covalent nature) stabilize the SO-SA complex:

- Face-to-face π - π -stacking between the electron rich π -basic quinoline ring of the SO and the electron poor π -acidic aromatic moiety of the SA.
- Directed intermolecular hydrogen bonding between the C=O of the SA and the carbamoyl -NH of the SO.
- Van der Waals interactions.
- A second hydrogen bonding between the amide -NH of the SA and the carbonyl of the SO carbamate.

- Steric interaction due to the sterically demanding *t*Butyl residue of the SO and the flexible leucine moiety of the SA [13, 49, 50].

All these interactions together with the tight ion pairing primary force result in a high degree of enantioselectivity. In **figure 1.9.** a complexation model for the interaction between the carbamoylated QN selector and DNB amino acids as well as DNP amino acids is shown.

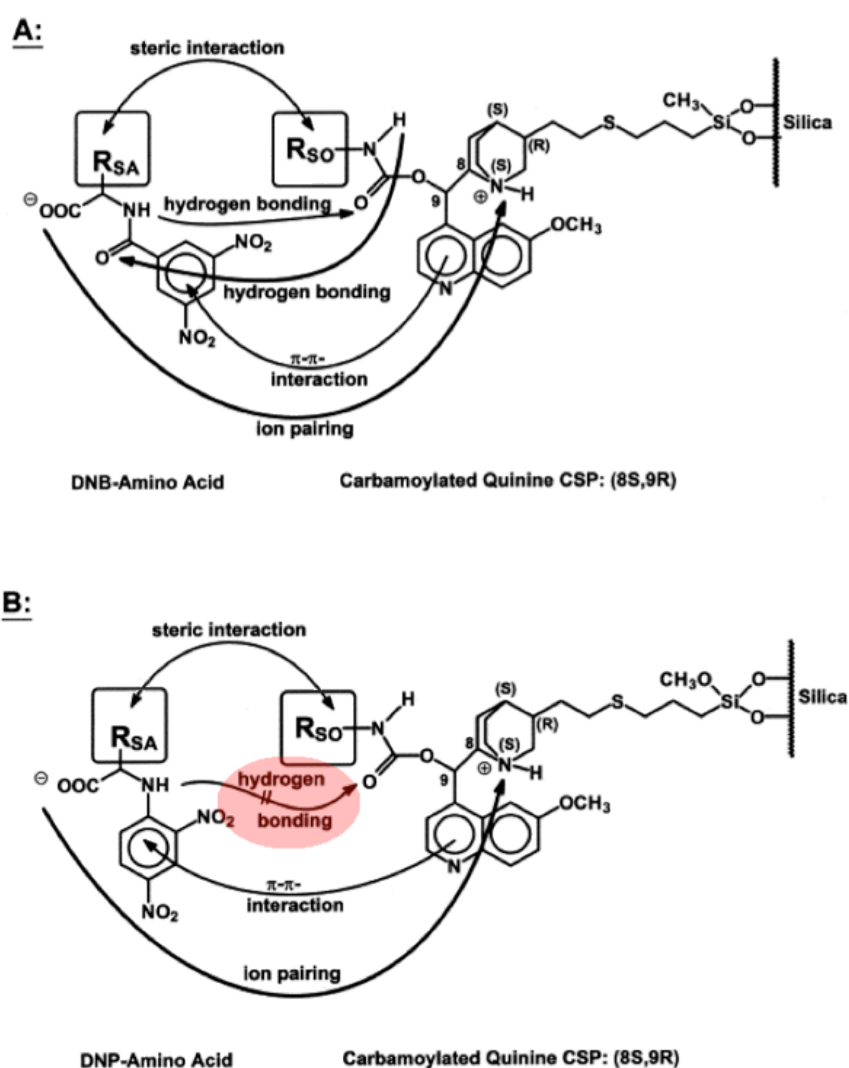

Figure 1.9.: Tentative chiral recognition model for a carbamoylated QN selector; (A) DNB amino acids; (B) DNP amino acids; R_{SA} = 2-methylpropane (Leu); R_{SO} = *t*Butyl; adapted and modified from [50].

The respective DNB-(*R*)-Leu enantiomer is much less retained in comparison to the (*S*)-enantiomer. The reason for this observation is a steric exclusion process. The (*R*)-enantiomer is not capable of forming a strong SO--SA complex, because of the

lack of accommodation in the well-defined binding pocket of the selector. Therefore stabilizing secondary interactions like hydrogen bonding and π - π -stacking cannot be achieved by the SA and the resulting overall retention is weak [13].

The importance of hydrogen bonding for enantioselectivity can be shown with DNB-*N*-methyl leucine. The only structural difference in comparison to DNB-Leu is, that the hydrogen of the amide is replaced by a methyl group. For this compound no enantioseparation was possible, a result that clearly shows the importance of hydrogen bonding in terms of chiral recognition or selectivity [49].

Another example for the hydrogen bonding influence is the interaction of the SO with a structurally similar compound, namely *N*-2,4-dinitrophenyl (DNP) leucine (see **figure 1.9.**). The lack of a carbonyl in the protecting group of leucine results in a significantly lower enantioselectivity coefficient and a reversal of elution order in comparison to the structurally related DNB-Leu compound [50].

1.8. Stoichiometric Displacement Model

As already mentioned above an ion exchange retention mechanism is reasonable for describing the interactions between cinchona based chiral selectors and acidic analytes. Besides the interactions taking place between SO and SA the mobile phase and its composition contributes to retention in a crucial way. Therefore the so-called stoichiometric displacement model allows explaining the dependency of retention times on the buffer concentration in the mobile phase, assuming that the pH-value stays constant (if one can speak of pH-value in polar organic mode consisting for example of MeOH as a bulk phase). A linear relationship between $\log k$ vs. $\log [X]$ (log of the counterion concentration in [mol.L⁻¹]) indicates an ion exchange mechanism (**equation [1.7]**).

$$\log k = \log K_z - Z \cdot \log[X] \quad [1.7]$$

This linear relationship demonstrates an important aspect of the stoichiometric displacement model. The higher the counterion-concentration, the lower the retention is. The counterions are also retained and act as a displacer for SA molecules. Due to this equation it is easily possible to adjust the retention times by simply diluting the mobile phase or adding buffer in a higher concentration.

However, for preparative purposes and mass spectrometric detection high buffer concentrations (and especially non-volatile buffers) should be avoided.

The slope Z in **equation [1.7]** is an empirical coefficient that contains information on how many charges in the ion-exchange process are involved (**equation [1.8]**):

$$Z = \frac{m}{n} \quad [1.8]$$

The divisor n is the effective charge number of the mobile phase counterion and the dividend m is the effective charge number of the selectand ion. One can see that an increase of the charge number of the counterion results in a flatter slope (e.g. citrate in comparison to acetate). In terms of elution strength the order citrate > phosphate > formate \geq acetate can be seen as a rule of thumb [13, 51].

If the slope is as steep/flat for both enantiomers, they both respond with the same sensitivity to an alteration of the counterion concentration in the mobile phase. Therefore the linear regressions are parallel for both stereoisomers. One additional aspect is that the selectivity coefficient stays almost constant, independent of the counter ion concentration. This allows an easy adjustment of the retention times.

The intercept K_Z in **equation [1.7]** is a system-specific constant, which is related to the mobile phase volume V_0 [L], the number of available ion-exchange sites q_x (representing the surface charge density [mol.m⁻²], the area of the surface S [m².g⁻¹] and the ion-exchange equilibrium constant K [L.mol⁻¹]. All these parameters are expressed in **equation [1.9]** [40, 51]:

$$K_Z = \frac{K \cdot S \cdot (q_x)^Z}{V_0} \quad [1.9]$$

In the case of cinchona alkaloid based selectors one should not forget that the anion-exchanger itself is a weak base and therefore acid-base equilibria have to be considered. In **equation [1.10]** the retention factor k is expressed taking these dissociation equilibria into account by the mass action model:

$$k = \phi \cdot \frac{K \cdot [SO^+] \cdot [SA^-]}{[X^-] \cdot ([SA^-] + [SAH])} \quad [1.10]$$

| | |
|----------|---|
| ϕ | phase ratio |
| K | ion-exchange equilibrium constant |
| $[SO^+]$ | concentration of protonated active ion-exchange sites |
| $[SA]$ | ionized, deprotonated SA |
| $[X^-]$ | concentration of counterions in the mobile phase |
| $[SAH]$ | concentration of non-ionized SA |

A more simplified version of **equation [1.10]** is given in **equation [1.11]**, which again indicates the inverse proportionality of the retention factor k and the counterion concentration $[X^-]$.

$$k = \phi \cdot \frac{1}{[X^-]} \cdot K \cdot \alpha_{SA}^* \cdot \alpha_{SO}^* \cdot [SO]_{tot} \quad [1.11]$$

Please note that in this case α is the degree of dissociation of SA and SO and $[SO]_{tot}$ means the total concentration of selector immobilized on the silica support, which is equivalent to q_x in **equation [1.9]** [51].

1.9. Immobilization Strategies

In the present master thesis two different strategies for the immobilization of the selectors on silica were employed:

- Radical activated thiol-ene “click” reaction
- Copper catalyzed azide-alkyne cycloaddition (Huisgen click chemistry)

1.9.1. Radical mediated thiol-ene addition

This reaction is often described as click reaction, although it does not always meet the prerequisites for a click reaction. Kolb et al. defined that “*the reaction must be modular, wide in scope, give very high yields, generate only inoffensive byproducts that can be removed by nonchromatographic methods, and be stereospecific (but not necessarily enantioselective)*” [52].

Besides the thiol-ene addition exist several other reactions with “click chemistry” characteristics such as metal-free dipolar cycloadditions, Diels-Alder reactions and thiol-based reactions like thiol-isocyanate, thiol-bromo and thiol-yne processes. In the present case azobisisobutyronitrile (AIBN) has been used as a radical starter for mediating the reaction. Apart from the radical pathway the thiol-ene reaction also works under a number of different conditions like catalytic processes mediated by nucleophiles, bases and acids [53] or supramolecular catalysis using β -cyclodextrin [54].

Figure 1.10.: Reaction mechanism for the thiol-ene addition; adapted from [53].

The reaction scheme for the hydrothiolation carried out via radical mediation is shown in **figure 1.10.**, in which the photoinitiator (PI) is AIBN and the radicals were formed via thermal activation of the radical starter in the present thesis. The reaction is a typical chain process consisting of initiation, propagation and termination. First the radical starter or photoinitiator decomposes due to heating or irradiation, respectively, and forms stable radicals, which treat thiols in order to form thiyl radicals. First step of the propagation is the addition of thiyl radical to an alkene compound yielding a carbon-centered radical as indicated above. The reaction is completed after the chain transfer of radical to another thiol-containing molecule. Thereby a new thiyl radical is generated and the reaction cycle is repeated. The third step of the radical chain process is the termination, which can be due to coupling processes of two radicals. The reaction can be carried out with almost any olefins, though terminal enes are more reactive in comparison to internal double bonds [53].

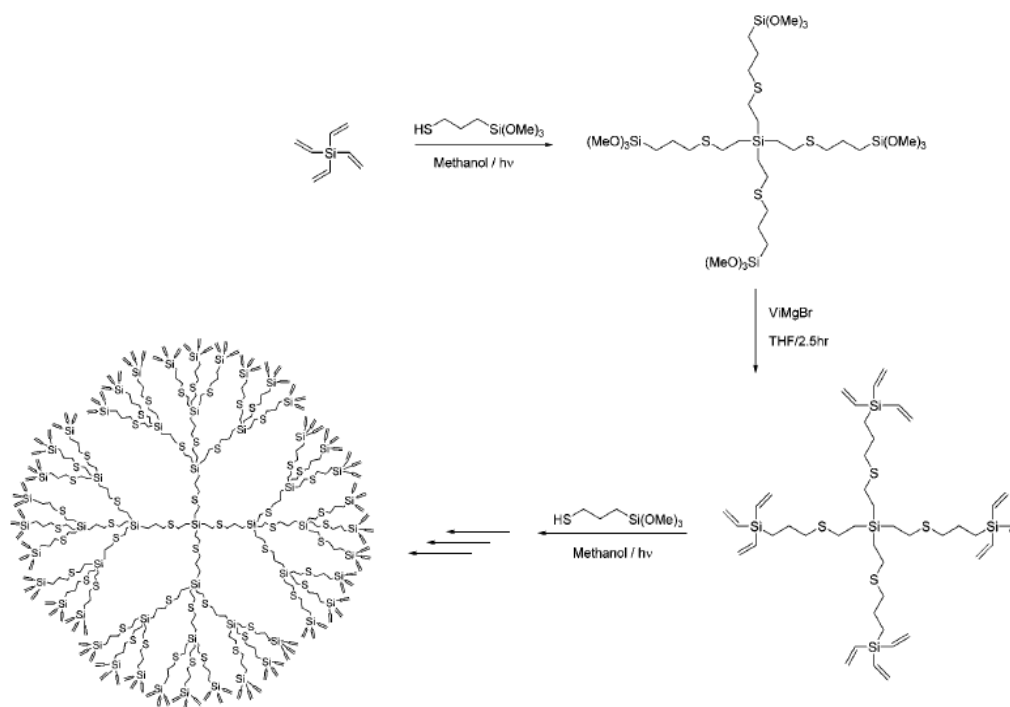

Figure 1.11.: Formation of carbosilane-thioether dendrimers via thiol-ene addition; adapted and modified from [55].

Due to the versatile application possibilities of the thiol-ene addition it is also used for immobilization of chiral selectors (containing olefins) onto mercaptopropyl-modified silica for example by Oberleitner et al. [42].

Further applications of this type of reaction are the synthesis of films and networks, the post-polymerization modification of polymers [53] and the formation of complex macromolecules such as dendrimers [56]. An illustrative example for this type of macromolecules is the formation of carbosilane-thioether dendrimers via photochemical induced hydrothiolation “click” chemistry followed by Grignard reaction (see **figure 1.11.**) [55].

1.9.2. Azide-alkyne cycloaddition

The copper(I) and base catalyzed Huisgen azide-alkyne click reaction has been discovered by Rostovtsev et al. in 2002 [57]. In this 1,3-dipolar cycloaddition 1,2,3-triazoles are formed from azides and terminal alkyne moieties [58]. The acceleration rate using a copper catalyst for this click reaction is tremendous in comparison to a non-catalyzed reaction (10^7 to 10^8) [59].

Copper can be used either directly as Cu(I) or as a coupled CuSO₄/ascorbate system in which Cu(II) as a precatalyst is reduced *in situ* by the ascorbate to the active Cu(I).

One disadvantage of Cu(I) salts like CuI is that they are sensitive to oxidation, which complicates operation and handling. Therefore research is focused on air-stable copper(I) complexes or copper(II) precatalysts only (without reducing agent). The latter is possible via oxidative homocoupling of alkynes (so-called Glaser reaction), in which considerable amounts of active Cu(I) are generated. One advantage of this procedure is that no external reductant is necessary [60].

Figure 1.12.: Cu(II) precatalyst complex with C18₆tren ligand; adapted and modified from [60].

One example for a Cu(II) precatalyst with C18₆tren as a ligand (tren = tris(2-aminoethyl)amine), which works without reducing agent at room temperature (RT), is presented in **figure 1.12.** and was developed by Harmand et al. [60]. Fortunately this complex is stable towards ambient oxygen.

In the present thesis Cu(I) iodide was used as a catalyst and acetonitrile as a solvent. Under these conditions high immobilization rates could be achieved. Full conversion was also observed in previous studies in toluene, dichloromethane, *N*-diisopropylethylamine, tetrahydrofuran and *N,N*-dimethylformamide as solvents. Tornøe et al. observed no reaction in the absence of CuI [58].

In **figure 1.13.** a proposed reaction mechanism for the click reaction is shown. In the presence of a base the Cu(I) covalently attaches to the terminal alkyne and in a stepwise or concerted way to the polarized azide moiety (step 1 and 2). Due to rearrangement of the bindings a triazole ring is formed (step 3 and 4) in the non-regiospecific reaction.

However, this type of reaction does not work with internal alkynes. As additional sources of Cu(I) compounds CuCl, CuBr and CuI can be used [58].

Figure 1.13.: Proposed catalytic mechanism for the formation of 1,2,3-triazoles; adapted from [61].

Besides the above mentioned copper catalysts it is also possible to use ruthenium(II)-based complexes for azide-alkyne cycloaddition catalysis. Boren et al. developed several complexes for the reaction of primary and secondary azides with both terminal and internal alkynes, whereas tertiary azides were not suitable [59]. Due to the simple feasibility of click reaction it is used for the immobilization of e.g. chiral selectors (containing alkynes) onto azidopropyl-modified silica [62].

2. Synthesis Results

2.1. Synthesis of Selectors and Chiral Stationary Phases

The first aim of the master thesis was the synthesis of new arylcarbamoylated cinchona-based chiral selectors (SOs) and chiral stationary phases (CSPs) for liquid chromatography. Four different types of chiral weak anion exchange (WAX) SOs (**SO1-4**) have been successfully synthesized. In combination with different SO loading on the silica support and different column dimensions, twelve columns (containing **CSP1-10**) have been prepared.

Therefore two different linkers (**L1**, **L2**), which enable the immobilization of the selector on the modified silica support were prepared. These isocyanates (**L1**, **L2**) were subsequently reacted with the hydroxyl group of cinchona alkaloids to afford our designed selectors. As building blocks dihydroquinine (**DHQN**) and dihydroquinidine (**DHQD**) were used.

The immobilization of the chiral SOs onto preactivated silica surfaces was carried out via the carbamoyl moiety implementing either radical addition with alkene thiol group or azide-alkyne Huisgen click chemistry, respectively.

2.1.1. Synthesis of Linker 1

Scheme 1 shows the synthetic route to **L1**. Commercially available 3,5-dichloro-4-hydroxybenzoic acid **1** was transformed into its 4-allyloxy-3,5-dichlorobenzoic acid allyl ester **2a** by reaction with allyl bromide. Purification of the product was achieved by flash column chromatography on silica. The ester group of the purified intermediate was then hydrolyzed with sodium hydroxide. Acidification with hydrochloric acid led to the carboxylic acid species **3a**. This intermediate was then treated with oxalyl chloride (COCl)₂ and dry *N,N*-dimethylformamide (DMF) as a catalyst to form the acyl halide **4a**. An alternative approach for activating the acid would be the reaction with thionyl chloride instead of oxalyl chloride, but (COCl)₂ is commonly milder [63]. One advantage of both reagents is that they produce only gaseous by-products.

The activated species was then converted into the acyl azide **5a** by nucleophilic substitution with sodium azide, which could be easily isolated by extraction. Heating

up the dry acyl azide led to the respective isocyanate **L1** via Curtius-rearrangement. The driving force of this reaction is the release of nitrogen. The crude product was purified by vacuum distillation and the colorless liquid product was stored at 4°C.

Scheme 1: Conditions: (a) allyl bromide, K_2CO_3 , acetone, reflux, 18 h, (b) NaOH, ethanol, water, reflux, 1 h, (c) HCl, 0°C, (d) $(COCl)_2$, DMF(catalyst), reflux, 1 h, (e) NaN_3 , acetone, water, 0°C, 1 h, (f) toluene, reflux, 2 h.

2.1.2. Synthesis of Linker 2

Scheme 2 shows the synthetic route to **L2**. Analogously, commercially available 3,5-dichloro-4-hydroxybenzoic acid **1** was transformed into its 4-propargyloxy-3,5-dichlorobenzoic acid propargyl ester **2b** by reaction with propargyl bromide. Purification of the product was achieved by flash column chromatography on silica. The ester group of the purified intermediate was then hydrolyzed with sodium hydroxide. Acidification with hydrochloric acid led to the carboxylic acid form **3b**. This intermediate was then treated with oxalyl chloride and dry DMF as a catalyst providing the respective acyl halide **4b**, which was subsequently converted into acyl azide **5b** by reaction with sodium azide, which could be easily isolated by precipitation and extraction. The procedure for isolating the acyl azide **5b** is slightly

different in comparison to the work-up of the acyl azide species described for **L1** above.

Scheme 2: Conditions: (a) propargyl bromide, K_2CO_3 , acetone, reflux, 18 h, (b) NaOH, ethanol, water, reflux, 1 h, (c) HCl, 0°C , (d) $(\text{COCl})_2$, DMF (catalyst), reflux, 1 h, (e) NaN_3 , acetone, water, 0°C , 1 h, (f) toluene, reflux, 3 h.

In the case of **L2** the acyl azide **5b** was first allowed to precipitate in an aqueous solution, afterwards filtered and washed in order to remove soluble by-products. The filtration cake was then dissolved in EtOAc, washed with water and saturated aqueous NaCl solution and dried over MgSO_4 to give a fully dry acyl azide **5b** after evaporation of the solvent. This work-up procedure is much more efficient with respect to drying than described above for the acyl azide species of **L1**.

Heating up the fully dry acyl azide led to the respective isocyanate **L2** via Curtius-rearrangement. Purification of the product by vacuum distillation was not possible due a high boiling point; hence the crude product was used directly for carbamylation of cinchona derivatives.

2.1.3. Synthesis of Selector 1

Scheme 3: Conditions: toluene, dibutyltin dilaurate (catalyst), reflux, N_2 , 18 h.

Scheme 3 shows the synthetic route to generate **SO1** (DHQN-type SO). Commercially available **DHQN** was dissolved in toluene and dried via azeotropic distillation. The carbamylation of dihydroquinine was carried out under nitrogen atmosphere with isocyanate **L1** and dibutyltin dilaurate (DBTDL) as a catalyst [64]. Purification of the product **SO1** was achieved by flash column chromatography on silica.

2.1.4. Synthesis of Selector 2

Scheme 4: Conditions: toluene, DBTDL (catalyst), reflux, N_2 , 18 h.

Scheme 4 shows the synthetic route to generate **SO2** (DHQD-type). Analogously to the procedure mentioned above, **DHQD** and **L1** were mixed together with the catalyst, the product was formed and afterwards purified by flash column chromatography on silica. **SO2** was then recrystallized from EtOH.

2.1.5. Synthesis of Selector 3

Scheme 5: Conditions: toluene, DBTDL (catalyst), reflux, N_2 , 18 h.

Scheme 5 shows the synthetic route to generate **SO3** (DHQN-type). Commercially available **DHQN** was dissolved in toluene and dried via azeotropic distillation. The carbamylation of **DHQN** was carried out under nitrogen atmosphere with purified isocyanate **L2** and DBTDL as a catalyst. Purification of the product was achieved by flash column chromatography on silica. Crystallization of **SO3** was not possible.

2.1.6. Synthesis of Selector 4

Scheme 6: Conditions: toluene, DBTDL (catalyst), reflux, N_2 , 18 h.

Scheme 6 shows the synthetic route to generate **SO4** (DHQD-type). Analogously to the procedure mentioned above, **DHQD** and **L2**, which was prepared *in situ* via Curtius rearrangement of acyl azide **5b**, were mixed, catalyst was added, the product was formed and afterwards purified by flash column chromatography on silica.

2.1.7. Immobilization of SO1 onto MP-Silica

Scheme 7: Conditions: methanol, azobisisobutyronitrile (AIBN), reflux, N_2 , 18 h.

Scheme 7 shows the immobilization step for **CSP1** (DHQN-type) via radical thiol-ene addition. Mercaptopropyl-modified silica (**MP-Silica**, loading of thiol groups app. 650 $\mu\text{mol/g}$ silica), **SO1** and AIBN as a radical starter were suspended in MeOH under nitrogen atmosphere. When AIBN is heated, it decomposes and forms two stable 2-cyanoprop-2-yl radicals and one molecule of nitrogen is released. The suspension was mechanically stirred in order to not damage the silica particles and heated under reflux. After 18 h the silica was filtered with a frit and washed. After drying under vacuum SO loading of **CSP1** was determined by elemental analysis (EA).

2.1.8. Immobilization of SO2 onto MP-Silica

Scheme 8: Conditions: methanol, AIBN, reflux, N_2 , 18 h.

Scheme 8 shows the synthetic route to **CSP2** (DHQD-type) via radical addition. The reaction was carried out in the same manner as mentioned above for the immobilization of **SO1**. The reagents were suspended in MeOH, heated and after

18 h the modified silica was filtered, washed, dried and SO loading of **CSP2** was determined by elemental analysis.

2.1.9. Synthesis of AzP-Silica

Scheme 9: Conditions: (a) toluene, *p*-toluenesulfonic acid (catalyst), reflux, 18 h, (b) NaN₃, dimethylsulfoxide (DMSO), tetrabutylammonium iodide (catalyst), 80°C, 72 h.

Scheme 9 shows the two-step synthetic route to azidopropyl-modified silica **AzP-Silica**. The synthesis was carried out similarly to a procedure published by Kacprzak et al. [62].

Silica and the catalyst were suspended in toluene and dried via azeotropic distillation. For surface-preactivation the haloalkylsilane was added to the reaction mixture and the mixture was stirred under reflux. The suspension was then filtered and washed with toluene and methanol. Chloropropyl-modified silica (**CP-Silica**) was dried under vacuum and chloropropyl-loading was determined by elemental analysis. **CP-Silica** was treated with NaN₃ in DMSO and tetrabutylammonium iodide as a catalyst to substitute the chloro-group by an azide group via nucleophilic halide/azide exchange. **AzP-Silica** was filtered, washed and dried under vacuum. Azide-loading of **AzP-Silica** was determined by elemental analysis. The analysis results showed a successful conversion of 85% from **CP-Silica** (740 μmol/g) to **AzP-Silica** with an azide-alkylsilane loading of 630 μmol/g.

2.1.10. Immobilization of SO₃ onto AzP-Silica

Scheme 10 shows the synthetic route to **CSP3** (DHQN-type) linked via 1,2,3-triazole group. The described procedure can be considered as a general synthetic pathway valid for **CSP5** (DHQN-type) as well. All azide click reactions were carried out in a way similar to the procedure published by Kacprzak et al. [47, 62, 65].

Scheme 10: Conditions: ACN, CuI (catalyst), *N,N*-diisopropylethylamine (DIPEA), room temperature (RT), 72 h.

ACN was degassed together with **AzP-Silica**, **SO3** and DIPEA (Hünig's base) in a resealable glass bottle. Catalyst was added under N₂ flushing and the sealed glass bottle was shaken for 72 h on an overhead shaker at room temperature. The reaction mixture was then filtered, washed and dried under vacuum. SO loading was determined by elemental analysis.

2.1.11. Immobilization of SO4 onto AzP-Silica

Scheme 11: Conditions: ACN, CuI (catalyst), DIPEA, RT, 72 h.

Scheme 11 shows the synthetic route to **CSP4** (DHQD-type) via azide-alkyne Huisgen cycloaddition. This synthetic procedure was also applied for **CSP6+7+8+9+10** (all of them are DHQD-type CSPs). Analogously to the procedure

mentioned above, the reagents were mixed, degassed, shaken for 72 h and afterwards worked up. SO loading was again determined by elemental analysis.

2.2. Summary of all synthesized CSPs

In combination with different SO loading of **SO1-4** onto silica, 12 different columns were prepared. **Table 2.1.** shows a summary of all synthesized CSPs together with dimensions of the packed columns, type and loading of the SO.

SO loading for the radical thiol-ene addition was 144 and 179 $\mu\text{mol/g}$ for **CSP1** (DHQN-type) and **CSP2** (DHQD-type), respectively. In comparison to the immobilization via Huisgen azide alkyne click reaction the SO loading achieved via thiol-ene addition was approximately three times lower. This could be due to the π -acidic character of the dichloro-substituted aromatic ring from the linker and the resulting radical scavenging property [66]. However, in former experiments of our working group the SO loading of about 200 $\mu\text{mol/g}$ showed good enantioseparation properties for *N*-protected amino acids [65].

Table 2.1.: Summary of synthesized CSPs and the corresponding packed columns.

| Column Number | CSP Number | SO | Type of SO | Dimensions of the column | Dimensions of Silica | SO loading [$\mu\text{mol/g}$] |
|---------------|------------|-----|------------|--------------------------|-------------------------|----------------------------------|
| 1 | CSP1 | SO1 | DHQN | 150x4 mm ID | 5 μm , 120 Å | 179 |
| 2 | CSP2 | SO2 | DHQD | | | 140 |
| 3 | CSP3 | SO3 | DHQN | | | 477 |
| 4 | CSP4 | SO4 | DHQD | | | 490 |
| 5 | CSP5 | SO3 | DHQN | | | 214 |
| 6 | CSP6 | SO4 | DHQD | | | 232 |
| 7 | CSP7 | SO4 | DHQD | | | 238 |
| 8 | CSP8 | SO4 | DHQD | | | 314 |
| 9 | CSP9 | SO4 | DHQD | | | 150 |
| 10 | CSP10 | SO4 | DHQD | | | 138 |
| 11 | CSP3 | SO3 | DHQN | 75x4 mm ID | 5 μm , 120 Å | 477 |
| 12 | CSP4 | SO4 | DHQD | | | 490 |

CSP7 and **CSP10** (both of them DHQD-type) do have slightly different chemical and physical properties in comparison to the other synthesized CSPs. **CSP7** is almost a one to one physical mixture of **CSP4** and pure **AzP-Silica**. This CSP was made for

comparative purposes to **CSP6** (DHQD-type) because of similar overall SO loading per gram silica.

CSP10 is a modified version of **CSP9**. The only difference is that the free azido-groups of **CSP9** – after immobilizing **SO4** – were endcapped with propargyl alcohol to give **CSP10**. The reaction scheme for endcapping is shown in **scheme 12**.

Scheme 12: Conditions: ACN, CuI (catalyst), DIPEA, RT, 72 h.

All columns were packed “in-house” into stainless steel columns with 150 mm length and 4 mm inner diameter, except for **columns 11** and **12**, which were packed into 75x4 mm ID columns for comparative purposes and a loading study. Packing of the columns was carried out using the conventional slurry packing method with iPrOH as slurry solvent and MeOH as packing solvent at a pressure of approximately 650 bars.

After packing the columns were flushed with aqueous EDTA solution to remove remaining CuI catalyst (**column 3-12**), water and MeOH.

2.3. Properties of the SOs

All four SOs (**SO1-4**) are derived from well-established cinchona alkaloid weak anion exchange (WAX) type SOs, namely **QN-AX** and **QD-AX** [67] and thus they are potentially suitable for the separation of acidic chiral compounds. Due to the pseudoenantiomeric behavior of the building blocks **DHQN** and **DHQP** [13, 49, 68, 69].

reversal of the elution order is possible. The immobilization can be carried out via two different strategies, either radical thiol-ene addition with AIBN or V65 as radical starter or copper(I)-catalyzed Huisgen alkyne-azide click chemistry.

There are multiple interactions with potential analytes (selectands, SAs) possible:

- Primary ionic interaction via the ionizable bicyclic tertiary amine in the quinuclidine ring at acidic mobile phase conditions (pK app. 9.8, entirely protonated at pH-values lower than 7.8 [70]). The quinoline amine (pK is app. 3.9) is mainly deprotonated under weakly acidic mobile phase conditions [70].
- Hydrogen-bonding via the carbamate -NH as donor and the carbonyl as an acceptor.
- Intermolecular π - π interactions via the aromatic π -basic quinoline ring and the aromatic ring of the linker.
- Steric interaction because of the sterically demanding aromatic dichloro-substituted linker.

All these interactions result in a potential ability for chiral recognition and make the SOs suitable for enantiomeric separation of chiral acidic SAs.

2.4. Immobilization Efficiency

In **table 2.2.** and **figure 2.1.** the dependency of the immobilization efficiency of offered SO is shown. All immobilizations were carried out using the same conditions for Huisgen click chemistry.

Table 2.2.: Dependency of immobilization efficiency of offered SO.

| CSP | Offered SO [$\mu\text{mol/g Silica}$] | Actual Loading [$\mu\text{mol/g Silica}$] | Loading Efficiency [%] |
|-----|--|--|---------------------------|
| 3 | 1044 | 477 | /// |
| 4 | 1014 | 490 | /// |
| 8 | 360 | 314 | 87 |
| 6 | 250 | 232 | 93 |
| 5 | 230 | 214 | 93 |
| 9 | 150 | 150 | 100 |

For **CSP3** (DHQN-type) and **CSP4** (DHQD-type) no selector loading efficiency is shown, because the SOs (**SO3** for **CSP3** and **SO4** for **CSP4**) were offered in app. 1.5 times molar excess referring to azidopropyl-loading on **AzP-Silica** with

629 $\mu\text{mol/g}$ silica. For **CSP5+6+8+9** the SOs were offered in deficit. With higher amount of offered SO the loading efficiency decreases. At a very low level of offered SO (150 $\mu\text{mol/g}$ for **CSP9**) immobilization can be regarded as quantitatively. In average 93% of the offered SO were immobilized.

The maximum of practical loading is approximately 500 $\mu\text{mol/g}$ silica, achieved with excess offer of SO. The stoichiometric maximum of loading capacity at 629 $\mu\text{mol/g}$ was never reached, even with a considerable excess of SO. This result reflects the impact of sterical hindrance.

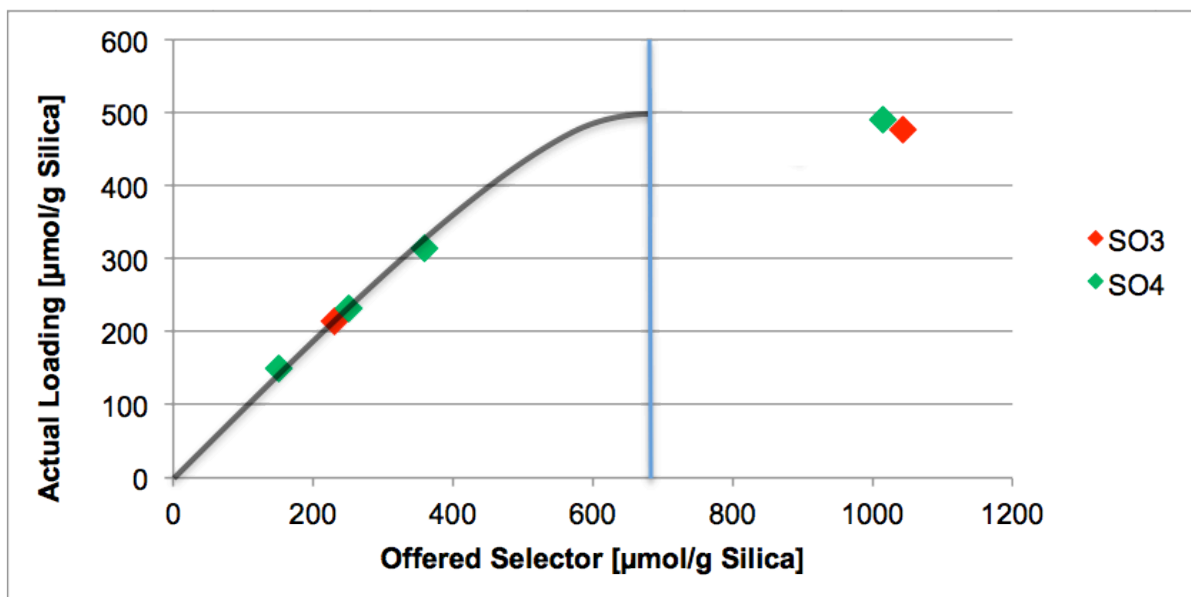

Figure 2.1.: Actual loading vs. offered SO3 or SO4; blue line: stoichiometric maximum (629 $\mu\text{mol/g}$).

Similar effects have been observed by Marshall et al. [71]. In the present case, the sterically demanding cinchonan derived SO leads to saturation phenomena at surface densities higher 500 $\mu\text{mol/g}$, rendering the preparation of more densely loaded CSP surfaces elusive.

3. Evaluation of the WAX-CSPs

3.1. Reference CSPs and Columns

For comparative purposes and the loading study as well, four additional columns were used (see **table 3.1.**). Three columns were packed with commercially available Chiralpak® QN-AX and QD-AX selector type silica materials [13]. In **figure 3.1.** the structures of these cinchona-derivatives-based weak anion exchange CSPs are depicted. These two quinine and quinidine derived carbamoylated reference materials show high capabilities in terms of resolution of chiral acidic compounds [49, 50, 67, 72, 73].

To further discover the influence of free azido-groups on the retention of analytes (selectands, SAs), one 150x4 mm ID column was packed with pure AzP-Silica as a non-chiral stationary phase (SP1).

Table 3.1.: Further used columns for Evaluation.

| Column Number | Type of Selector | Dimensions of the column | Dimensions of Silica | Selector loading [$\mu\text{mol/g}$] |
|---------------|------------------|--------------------------|------------------------------------|--|
| 13 | QN-AX | 150x4 mm ID | | |
| 14 | QD-AX | 150x4 mm ID | 5 μm , 120 \AA | app. 340 |
| 15 | QD-AX | 75x4 mm ID | | |
| 16 | AzP | 150x4 mm ID | 5 μm , 120 \AA | 629 |

3.2. Analytes

For the evaluation of the CSPs a broad set of chiral SAs was used. Since all the synthesized CSPs are weak anion exchange type CSPs based on cinchona alkaloids and the retention is primarily driven by an ion exchange mechanism [42, 49, 67], the majority of the SAs consists of chiral organic acids and acid derivatives including 31 *N*-protected amino acids (BOC-Gly and DNZ-Gly as achiral compounds), 17 carboxylic acids, nine *N*-protected aminophosphonates and three *N*-protected aminosulfonic acids. For determining the elution order single enantiomers were used if they were available. To further proof the concept of anion exchange four zwitterionic and three basic compounds, which should stay non-retained [42], were also used for the evaluation of the CSPs. In **figures 3.2. to 3.9.** the structures of all SAs used for evaluation are shown. The SAs were commercially available, synthesized earlier in the working group of Prof. Lindner or were kind gifts of other working groups [74, 75].

3.3. Materials and Methods for Evaluation

The chromatographic screening of the columns was carried out on a 1290 series Infinity HPLC system from Agilent Technologies (Waldbronn, Germany) consisting of an automated sampler, solvent tray, a binary pump with two channels, a degasser, a thermostated column compartment for six columns and a diode array detector (DAD). All SAs were detected at a wavelength of 254 nm. The columns were thermostated at $25.0 \pm 0.1^\circ\text{C}$. Data processing was carried out with a ChemStation chromatographic data software from Agilent Technologies and Excel spreadsheet software from Microsoft Corporation.

The loading studies were carried out on an 1100 series HPLC system from Hewlett Packard (Waldbronn, Germany) consisting of an automated sampler, solvent tray, a binary pump with two channels, a degasser, a thermostated column compartment and a multiple wavelength detector (MWD). The SAs were detected at a wavelength of 270 nm. The columns were thermostated at $25 \pm 0.1^\circ\text{C}$. Racemic Ac-Phe (obtained from Sigma) was dissolved in pure MeOH at a sample concentration of 100 ± 0.1 mg/mL. The injection volume was 5 to 100 μL . Elution was performed in isocratic mode with a flow rate of 0.5 mL/min for 15 min. As a starting mobile phase the same composition as for screening was used (see below).

For screening purposes 5 μL of each SA-solution with a concentration of 1.0 ± 0.1 mg/mL in MeOH were injected. For determining the elution order in a racemic mixture a single enantiomer was – if available – measured as well. Elution was performed in isocratic mode with a flow rate of 1.0 mL/min at $25.0 \pm 0.1^\circ\text{C}$. The composition of the mobile phase used for screening was MeOH/AcOH/NH₄OAc (99/1/0.25 v/v/w). The mobile phase was degassed by sonication prior to use. This mobile phase composition is a diluted version of a commonly and successfully used mobile phase in polar organic (PO) mode used e.g. by Kacprzak et al. [47].

The acetic acid in the mobile phase is necessary to provide weakly acidic conditions in the chromatographic system for protonation of the selector. The acidic additive and buffer salt also act as co- and counterion that determines the electrostatic interactions between SA and CSP [76]. Because buffer salts also act as competitors to the SAs and are therefore displacers for the SAs, the retention time is highly dependent on an ion strength and ion charge in the mobile phase.

3.4. Chromatographic Parameters

For evaluation of the different CSPs it is necessary to define the main chromatographic parameters:

- Retention Factor k_i :

$$k_i = \frac{t_i - t_0}{t_0} \quad [3.1]$$

The retention factor k_i reflects the binding strength between a SA or single enantiomer of the SA and the SO immobilized on the surface of a CSP. The larger the value of k_i , the stronger is the interaction. The retention factor is calculated by dividing the difference between the retention time and the void time by the void time.

- Selectivity coefficient α :

$$\alpha = \frac{k_2}{k_1} \quad [3.2]$$

The selectivity coefficient or separation factor α describes the ratio of the retention factors of two separated SAs or enantiomers. It is calculated by dividing the retention factor of the second eluted enantiomer (k_2) by the retention factor of the first eluted enantiomer (k_1). If separation takes place, the α -value is higher 1. For preparative purposes high selectivity is one important prerequisite.

- Resolution R :

$$R = \frac{\sqrt{N_{av}}}{4} \cdot \frac{\alpha - 1}{\alpha} \cdot \frac{k_2}{1 + k_{av}} \quad [3.3]$$

The resolution R indicates the quality of separation and consists of three terms (efficiency, selectivity and retention). The first term includes the average number of theoretical plates for separation N_{av} (see **equation [3.4]**). This term

describes the separation performance. The resolution is directly proportional to the square root of N_{av} . The higher the number of plates, the higher is the resolution. The second term includes the selectivity coefficient α . The retention factor of the second eluted enantiomer (k_2) and the average retention factor for both enantiomers are described in the third term.

- Number of theoretical plates N_i :

$$N_i = 5.54 \cdot \left(\frac{t_i}{w_{i1/2}} \right) \quad [3.4]$$

The number of theoretical plates N_i indicates the separation performance. N_i informs on the number of equilibrium settings of the SA between the mobile and stationary phase. It is dependent on the quality of packing of the column and the SO density on the surface of the silica material. N_i is calculated by dividing the retention time by the width of the peak at half maximum $w_{i1/2}$.

Please note that in the following discussion N_i always refers to the respective column length.

3.5. Influence of immobilization strategy

In **figures 3.10.** to **3.12.** one can see the influence of the immobilization strategy on the performance of the same selector. CSP2 (DHQD-type) in column 2 was prepared by the radical thiol-ene addition, while CSP9 (DHQD-type) in column 9 was immobilized by alkyne-azide click chemistry. This is the only structural difference between the two CSPs, because the remaining structures of the SOs are the same. SO loading of CSP2 was 144 $\mu\text{mol/g}$ and for CSP9 150 $\mu\text{mol/g}$, so they both are comparable in terms of the SO density on the surface. The chromatographic conditions used were the same for both measurements.

The acidic compounds are at least partially separated; the elution order for amino acid derivatives is always *L* before *D*, except for DNB-Pro, which was observed for any other DHQD-type CSP as well. DNB-*N*-Me-Leu was not separated on the column 9, and the alpha-value on the column 2 was very low. Basic compounds like QN, QD, clenbuterol hydrochloride and zwitterionic compounds are neither retained

nor separated; they all had a k -value below 0.3. **Figure 3.10.** shows that the k -values are comparable for both columns. Column 9 exhibits an increased selectivity for the aminophosphonic compound PI-2-15-1 ($\alpha = 1.71$) in comparison to column 2 ($\alpha = 1.16$). The alpha-values for the other SAs are comparable (see **figure 3.11.**). These results demonstrate that both types of CSPs are capable of separating a variety of chiral acidic compounds, independently on structural variations and acidity.

Figure 3.10.: Dependency of retention of the immobilization strategy; column 2: DHQD-type, 140 $\mu\text{mol/g}$; column 9: DHQD-type, 150 $\mu\text{mol/g}$.

In terms of resolution the behavior is different (see **figure 3.12.**). R is always higher for the radical thioether like CSP. One example is DCB-Leu: Resolution is about 13 for column 2 and 8 for column 9. This is based on the different number of theoretical plates for each column, because k and alpha-values are comparable.

For column 2 N_{av} is about 5300 (all measured samples), for column 9 the number of theoretical plates is a factor of 2.3 lower ($N_{av} = 2300$, all measured samples). One reason for different resolution-values could be a different packing density of the two columns, because packing also influences the number of plates and therefore the resolution.

Figure 3.11.: Dependency of selectivity of the immobilization strategy; column 2: DHQD-type, 140 µmol/g; column 9: DHQD-type, 150 µmol/g.

The same results and trends were observed when comparing columns 1 and 5, the corresponding DHQN-type CSPs with 179 µmol/g and 214 µmol/g SO loading, respectively.

Figure 3.12.: Dependency of resolution of the immobilization strategy; column 2: DHQD-type, 140 µmol/g; column 9: DHQD-type, 150 µmol/g.

3.6. Influence of free Azide groups on Retention

The influence of free azide-groups on silica is shown in **figure 3.13**. The effect of free azide-groups could be important for low loaded CSPs, because there are free

azide groups not-clicked with an alkyne residue. The azide itself is highly polarized and therefore it can potentially interact with polarized groups of SAs. This study was performed with pure AzP-Silica as a non-chiral stationary phase (SP1, column 16).

The influence of pure AzP-Silica is low. There is – of course – no enantioselectivity and no retention as well, except a very low retention value for QN and QD. The other SAs used for this study eluted before t_0 . The overall effect is quite limited and there is almost no contribution with regard to retention.

The average k -value is below zero ($k_{av} = -0.1$). Furthermore, Franco et al. carried out retention studies with pure MP-Silica as a reference material and they documented that there is also no substantial contribution of the carrier material with respect to retention [42]. They have observed average k -values below 0.1 for a variety of N -protected amino acids as well.

Figure 3.13.: Influence of free azide-groups on silica; column 16: AzP-type, 629 $\mu\text{mol/g}$.

3.7. Influence of Endcapping

In figures 3.14. and 3.15. the influence of endcapping in terms of selectivity and resolution is shown. For this study CSP9 (DHQD-type) was used, part of which was endcapped with propargyl alcohol to give CSP10. SO loading is almost the same after endcapping (138 $\mu\text{mol/g}$ for CSP10 in comparison to 150 $\mu\text{mol/g}$ for CSP9), 12 μmol (8%) of SO per gram silica have been cleaved off during immobilization and the work-up procedure. The average number of theoretical plates for column 9 was $N_{av} = 2324$, for column 10 $N_{av} = 3486$ (factor of 1.5).

Even with this low amount of immobilized SO at least partial separation of the SAs was possible. Only hydroxyphenyllactic acid was not separated on column 10, on the other hand, partial separation on column 9 was achieved ($\alpha = 1.07$).

The k_1 - and k_2 -values (not shown here, see **appendix**) were generally lower for the endcapped material. This can be explained by the slightly lower SO loading. The aminophosphonate derivative PI-2-15-1 exhibits, however, slightly higher retention on column 10.

Figure 3.14.: Influence of endcapping in terms of selectivity; column 9: DHQD-type, 150 $\mu\text{mol/g}$; column 10: DHQD-type, 138 $\mu\text{mol/g}$ (endcapped).

DCB-Leu and the two aminosulfonic acid derivatives P-DML-ACHSA and P-DCL-ACHSA do have higher k_2 -values on column 10 compared to column 9.

There is a trend that alpha-values for *N*-protected amino acid derivatives are slightly increased for the endcapped material, so selectivity is better. On the other hand, the resolution is lower. For the tested aminophosphonate and the aminosulfonic acid derivatives resolution is increased, which is in agreement with the trend observed for selectivity coefficient α .

Figure 3.15.: Resolution-influence of endcapping; column 9: DHQD-type, 150 µmol/g; column 10: DHQD-type, 138 µmol/g (endcapped).

3.8. Reversal of the Elution Order

Referring to the pseudoenantiomeric behavior of the building blocks DHQN (8*S*,9*R*) and DHQD (8*R*,9*S*; both of them 1*S*,2*R*,3*S*) [13, 49, 67-69], reversal of the elution order was observed for every single separated racemic SA, without any exception. The DHQN and DHQD derived CSPs show exactly opposite behavior in terms of enantioselectivity as indicated in **figure 3.16**. for the separation of P-DCL-ACHSA (*S,S* > *R,R*) on column 1 (DHQN-type) and column 2 (DHQD-type). For the *N*-protected amino acid derivatives elution order was always *D* before *L* for DHQN-type CSPs except for DNB-Pro (*L* before *D*). The DHQD-type SOs behaved just the opposite way. This indicates an equal separation mechanism for all *N*-protected amino acid derivatives except for DNB-Pro.

Maier et al. reported that “*the absolute configuration of the C₉ stereogenic center in the cinchonan backbone determines the elution order of these analytes. SOs having (9*R*)-configuration, i.e., QN- [...] derived CSPs, show stronger retention for N-acylated (S)-amino acids, whereas their (R)-enantiomers interact more strongly with QD- [...] based selectors*” [67].

Figure 3.16.: Reversal of the elution order on changing from DHQN to DHQD-type CSPs; column 1: DHQN-type, 179 $\mu\text{mol/g}$, column 2: DHQD-type, 140 $\mu\text{mol/g}$.

3.9. Comparison of DHQN and DHQD-type CSPs

Column 5 (DHQN-type) and column 6 (DHQD-type) are well suited for the comparison of DHQN and DHQD-type CSPs because they have approximately the same amount of SO immobilized on the surface via Huisgen alkyne-azide click chemistry. CSP 5 in column 5 has a SO loading of 214 $\mu\text{mol/g}$ in comparison to CSP6 in column 6 with a loading of 232 $\mu\text{mol/g}$ silica.

In **figure 3.17**, the ratio of partial separation, baseline separation and no separation for 58 acidic chiral SAs for columns 5 and 6 is shown. In case of the DHQD-type CSP (column 6) 53% of the 58 acidic SAs were baseline separated and 19% were partially separated. All together separation was observed for 72% of the acidic SAs.

The percentage of baseline separated SAs for the DHQN-type CSP (column 5) is lower (50%), but all together 72% of the SAs were at least partially separated. The value for not separated compounds is equal for both columns (28%). The observed partial separation of Trp on the DHQN-type CSP5 ($\alpha = 1.14$, $R = 0.48$) is not included in the calculation. This separation was not observed for CSP6. The other three zwitterionic compounds and the three basic compounds were not separated. For the DHQD-type CSP no zwitterionic and basic compound was separated.

Figure 3.17.: Ratio of partial separated ($0 < R < 1.5$), baseline separated ($R \geq 1.5$) and not separated acidic SAs ($R = 0$) observed for column 5 (DHQN-type, 214 $\mu\text{mol/g}$) and column 6 (DHQD-type, 232 $\mu\text{mol/g}$).

However, one should consider that these results were observed for just one mobile phase (polar organic mode, MeOH/AcOH/NH₄OAc 99/1/0.25 v/v/w). Variation of the mobile phase could of course alter the percentages for partial, baseline and no separation.

3.9.1. Selectivity

In **figure 3.18**, the average values of the selectivity coefficients for the different groups of acidic SAs are shown. A general trend for all the groups of SAs is that selectivity is increased for the DHQD-type CSP6. The *N*-protected phenylalanine derivatives represent an exception in two aspects:

1. Both for DHQN and for DHQD-type CSP the average alpha-value is the highest compared to the other groups of chiral acidic SAs.
2. The behavior, in terms of selectivity, is exactly the opposite in comparison to the other groups of acidic compounds – the DHQN-type CSP has an increased selectivity by a factor of 1.67. This is because the selectivity for DNZ-Phe is doubled in case of the DHQN-type CSP (21.4 for DHQN-type and 10.4 for DHQD-type CSP).

Alpha-values of other *N*-protected phenylalanine derivatives are increased for the DHQD-type CSP (column 6).

Figure 3.18.: Average α -values for the different groups of acidic SAs; column 5: DHQN-type, 214 $\mu\text{mol/g}$; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

The carboxylic acid derivatives, in particular profens (representing aryl propionic acids) are hard to separate. In this regard Lämmerhofer et al. noticed that this type of carboxylic acids is not capable of forming additional dipole interaction or hydrogen bonding due to the absence of an additional polar unit between the aromatic group and the chiral center [49].

3.9.2. Resolution

A comparison between CSP5 and 6 in terms of average resolution shows a clear trend for higher resolution for the DHQD-type CSP. **Figure 3.19.** represents a graphical illustration of this behavior. Generally, the resolution is increased for every group of SA by a factor of 1.27. The resolution dependent average number of theoretical plates N_{av} is increased by a factor of 1.14 for the DHQD-type CSP as well.

In combination with the observed increase of selectivity (see **chapter 3.9.1.**), one can conclude that the DHQD-type SO is generally more suitable for the separation of chiral acids.

Figure 3.19.: Average resolution-values for the different groups of acidic SAs column 5: DHQN-type, 214 $\mu\text{mol/g}$; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

3.10. Separation capability compared between Columns 1 to 6

For comparing structural influences on the separation behavior it is reasonable to do that with the results obtained for the column with the highest separation capability. In **table 3.2.** the results of the separation studies between columns 1 to 6 are summarized for the 58 chiral acidic SAs. Please note that BOC-Gly and DNZ-Gly are non-chiral acidic compounds and therefore are not included in the calculation below. Because all the CSPs represent weak anion exchange type CSPs, the set of non-acidic SAs is excluded from the considerations as well.

The results obtained for columns 7 to 12 are not included in this study because in this case a smaller set of samples was used for screening and therefore it is not possible to do systematic comparative studies on the structural influence of the SAs. The largest part of baseline separated chiral acidic compounds was observed for column 2 (55%, DHQD-type CSPs). The smallest part of not separated compounds was observed for column 5 and 6 (both 28%).

Out of these results column 6 is the column with the highest separation capability and therefore the results observed for column 6 were used for comparing structural influences of the SAs on the separation behavior.

Table 3.2.: Overall separation capabilities of columns 1 to 6; partial separation $0 < R < 1.5$; baseline separation $R \geq 1.5$; no separation $R = 0$.

| Column | CSP Type | SO loading [$\mu\text{mol/g}$] | Baseline Separation [%] | Partial Separation [%] | No Separation [%] |
|----------|----------|----------------------------------|-------------------------|------------------------|-------------------|
| Column 1 | DHQN | 179 | 52 | 17 | 31 |
| Column 2 | DHGD | 140 | 55 | 16 | 29 |
| Column 3 | DHQN | 477 | 29 | 33 | 38 |
| Column 4 | DHGD | 490 | 34 | 31 | 34 |
| Column 5 | DHQN | 214 | 50 | 22 | 28 |
| Column 6 | DHGD | 232 | 53 | 19 | 28 |

3.11. Influence of analyte structure on Separation

In **chapter 3.10.** the column with the highest separation capability turned out to be column 6. In this case the largest part of chiral acidic compounds was at least partially separated (72%). CSP6 in column 6 has got a SO loading of 232 μmol of SO₄ (DHGD-type) per gram CSP.

3.11.1. *N*-protected leucine derivatives

DNB-*N*-Me-Leu was not separated on column 6 (see **figure 3.20.**). On the other side, the enantioselectivity is dramatically increased for the structurally related DNB-Leu, which shows the highest values of enantioselectivity and resolution for the *N*-protected leucines. The only difference between these two SAs is that the amido hydrogen of DNB-Leu is alkylated and replaced by a methyl group for DNB-*N*-Me-Leu. Evidently this amido hydrogen is essential for chiral recognition and enantioselectivity, respectively. Lämmerhofer et al. observed the same result when comparing these two SAs [49]. This behavior is also in agreement with the results previously found by Mandl et al. [50].

Without the capability of forming a hydrogen bond between the amido hydrogen as a donor and the carbonyl of the SO carbamate as an acceptor, enantioseparation is not possible for the DNB-Leu derivatives. The k_2 -value for the methylated derivative

is 4.93 in comparison to 14.88 for the non-methylated compound, so there is much stronger interaction between the cinchona based carbamoylated SO and the non-methylated DNB-Leu due to hydrogen bonding. Since the amido hydrogen of DNB-Leu is close to the center of chirality, enantiodiscrimination between *L* and *D* is possible.

Figure 3.20.: Comparison of selectivity α and resolution *R* between *N*-protected leucine derivatives; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

When comparing DCB-Leu and A-DCL-Leu, the structural difference is based on the *para*-allyloxy substitution at the protecting benzoyl group. Both of them are analogously *meta*-substituted with two chloro atoms at the benzoyl protecting group. The k_2 -values are slightly increased for A-DCL-Leu ($k_2 = 5.09$) compared to DCL-Leu ($k_2 = 4.67$). The retention factors for the first eluted enantiomers are almost equal. Substitution with an allyloxy group also increases the enantioselectivity and resolution – this effect could be either due to the increased sterical demand of the rotating allyloxy group or due to different polarization of the aromatic system because of the introduction of an oxygen atom.

Complete substitution of all aromatic H-atoms with five fluorine atoms results in descending enantioselectivity and resolution. It has to be noted that fluoro-substitution generally results in special behavior. Of course no fluorophilic interaction with the SO can take place and therefore retention is low. The opposite result was observed e.g. by Kohout et al. when using trifluoromethyl substituted SOs based on

mefloquine as a basic module [77]. They observed that the trifluoromethyl groups of the SO are capable of promoting the recognition of PFB-Leu.

The separation parameters observed for Z-Leu are similar to those observed for PFB-Leu. Introducing an oxycarbonyl with a flexible CH₂ spacer instead of carbonyl for Bz-Leu results in decreased selectivity and resolution. One can conclude that the carbamate is less interacting with the SO in comparison to the amide.

For disubstituted Bz-Leu the selectivity coefficient decreases in the order DNB-Leu > BTFMB-Leu > DCB-Leu. In terms of resolution the behavior is slightly different, just BTFMB-Leu and DCB-Leu are exchanged in the order. Compared to the other leucine derivatives DNB-Leu shows extraordinary high values for α and R . The retention time of the stronger retained D enantiomer is approximately four times higher than for the corresponding D enantiomer of DCB-Leu. Due to the negative mesomeric effect of the nitro groups the aromatic ring is a stronger π -acid compared to DCB-Leu and the other benzoyl-substituted leucines. This of course leads to the stronger interaction with the π -basic SO.

3.11.2. *N*-protected phenylalanine derivatives

Concerning *N*-protected phenylalanine derivatives the selectivity coefficient and resolution-value are strikingly increased for DNZ-Phe ($\alpha = 10.43$ and $R = 20.01$). The same result was observed for DNB-Leu (see **chapter 3.11.1.**). The average α -value for all the other *N*-protected phenylalanine derivatives is about 8 times lower ($\alpha_{av} = 1.32$, $n = 6$).

In **figure 3.21.** the selectivity coefficients and resolution-values for the *N*-protected phenylalanine derivatives are shown with the exception of DNZ-Phe. The highest resolution was observed for Bz-Phe, followed by Ac-Phe. These two compounds are both baseline separated on column 6. In case of Ac-Phe - which is the smallest compound of the phenylalanine derivatives - no interaction with the SO is possible for the protecting group except hydrogen acceptance via the carbonyl group and of course hydrogen donation via the amido hydrogen. Switching from α -Phe to β -Phe derivatives resulted in a decrease in both selectivity and resolution.

Introducing benzyloxycarbonyl instead of benzoyl results in decreased selectivity and resolution. Hence the carbamate may be less interacting with the SO. The same result was observed for Bz-Leu and Z-Leu (see **chapter 3.11.1.**) This result indicates

that the distance between the center of chirality and the aromatic moiety of the α -amino acid derivative including flexibility and conformation are of great importance for optimal interaction. This conclusion was also drawn by Maier et al. [67].

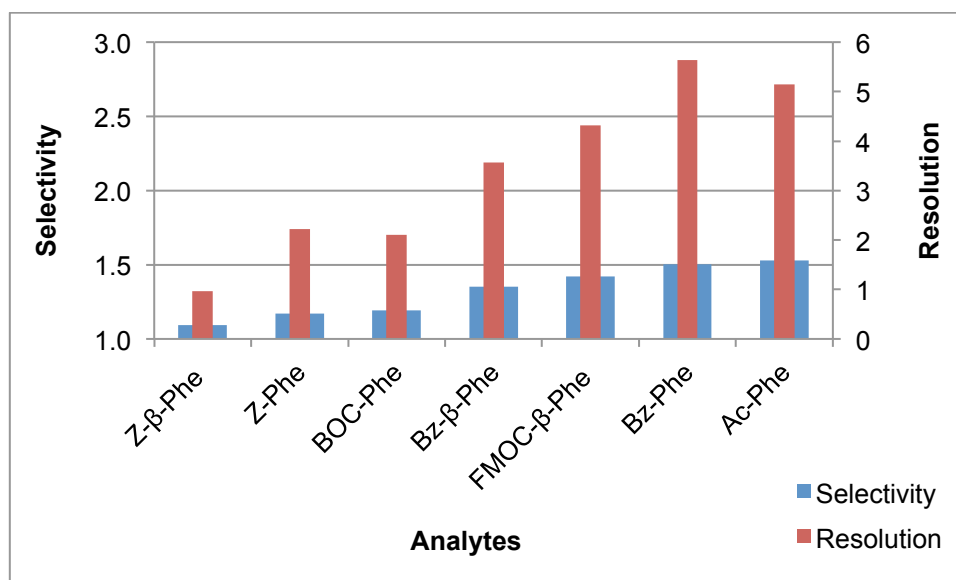

Figure 3.21.: Comparison of selectivity α and resolution R among N -protected phenylalanine derivatives; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

3.11.3. N -protected amino sulfonic acids

In **figure 3.22.** the effect of substitution for three N -protected aminosulfonic acids is shown. All three of them are comparable according to selectivity ($1.10 \leq \alpha \leq 1.19$). The non-substituted Bz-ACHSA gives the lowest value for resolution ($R = 1.44$). P-DML-ACHSA and P-DCL-ACHSA are sterically more demanding in comparison to Bz-ACHSA. In combination with the influence of the oxygen of the propargyloxy-substituent on the electron distribution this may result in a higher resolution for substituted Bz-ACHSA derivatives. Exchanging the methoxy-substituents by chlorine results in an increase of resolution.

Figure 3.22.: Comparison of selectivity α and resolution R within the series of *N*-protected aminosulfonic acids; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

3.11.4. *N*-protected aminophosphonates

For structure comparative studies a number of different aminophosphonate derivatives was also employed. In **figure 3.23.** the summarized results in terms of selectivity coefficients and resolution are shown for column 6 (DHQD-type, 232 $\mu\text{mol/g}$).

One can clearly see that PI-2-4-3 (*N*-FMOC-protected α -phenylphosphonic acid methyl ester) shows the largest value both for selectivity and resolution. Both values are slightly decreased when exchanging the α -phenyl by a butyl residue as it was observed for PI-2-15-1. Exchanging the α -phenyl by a benzyl residue results in a drop of the two chromatographic parameters.

The only structural difference between PI-2-15-1 and PI-2-87-1 is the protecting group (Z in case of PI-2-87-2 instead of FMOC). In this case the FMOC-protected aminophosphonate shows much higher resolution and a selectivity coefficient that is almost a factor of 1.4 higher in comparison to Z-protection. Exchanging the methyl ester by a benzyl ester in case of PI-2-87-1 and PI-3-67-1, respectively, slightly increases the resolution, wherein the α -values are almost equal. Hydrolysis of the ester results in compound PI-2-56-2. There was just a very slight separation observed for the free phosphonic acid derivative compared to the methyl ester. The shorter the backbone alkyl chain, the higher selectivity was observed, although there is almost no difference between ethyl and propyl side chain for compound PI-2-38-1 and PI-2-34-1.

Figure 3.23.: Comparison of selectivity α and resolution R among N -protected aminophosphonates; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

The aminophosphonate derivative PI-1-89-1 was not separated on column 6 (DHQD-type CSP). This compound could never be separated on DHQD-type CSPs (column 2, 4 and 6). Exactly the opposite was observed for DHQN-type CSPs (column 1, 3 and 5), where at least partial separation could be observed. On column 13 and 14, which are standard QN-AX and QD-AX CSPs for comparative purposes, compound PI-1-89-1 could be separated on both QN and QD type CSP.

3.11.5. Fmoc-protected amino acids

Because of the larger number of Fmoc-protected amino acids present in the set of SAs, it is also possible to compare them with respect to the amino acid residue. Lämmerhofer et al. observed that these aryloxycarbonyl as well as the alkyloxycarbonyl amino acid derivatives behave in a similar way to their amido congeners because they are also capable of hydrogen donation and acceptance [49]. Since the elution order is the same when comparing DHQN and DHQD-type CSPs, an analogous mechanism for chiral separation can be assumed.

No separation was observed for Fmoc-Gln. The retention factor for the Fmoc-Gln is $k = 0.14$, so almost no interaction with the SO was possible. Glutamine is an amino acid with a polar side chain, namely a primary amide. Hence a competitive hydrogen bonding of the primary amide group could be possible.

Separation could be possible with a different mobile phase composition, but this has not been investigated so far.

Figure 3.24.: Comparison of selectivity α and resolution R within the series of *N*-protected amino acids; column 6: DHQD-type, 232 $\mu\text{mol/g}$.

Interestingly, FMOC-Asn was partially separated on column 6. This observation cannot be explained without further experiments and mobile phase variations, because the behavior should be similar to FMOC-Gln (both amino acids contain a primary amide). When comparing FMOC-Aze and FMOC-Pro (both containing a heterocyclic ring consisting four or five atoms), one can observe no significant difference in terms of α and R .

3.12. Comparison of Columns with the same total amount of SO

Column 6, 7 and 12 do almost have the same total amount of immobilized SO per column (SO₄, DHQD-type SO), but with different properties. The CSP in column 6 has a SO loading of 232 $\mu\text{mol/g}$ (column dimensions: 150x4 mm ID), column 12 is a short 75x4 mm ID column with a SO loading of 490 $\mu\text{mol/g}$ and column 7 is a homogenous physical mixture made prepared from the same material used for packing column 12 and pure AzP-Silica (column dimensions: 150x4 mm ID). All in all almost the same total amount of SO is in all three columns. In **figure 3.25**, a model for these three columns is shown.

When comparing all three columns with the same flow rate (1.0 mL/min), the retention times t_1 of the first eluted enantiomers are similar for most of the SAs, but retention time of column 6 is in most cases the longest (see **figure 3.26**).

This result indicates that the overall retention is predominantly dependent on the total amount of SO per column.

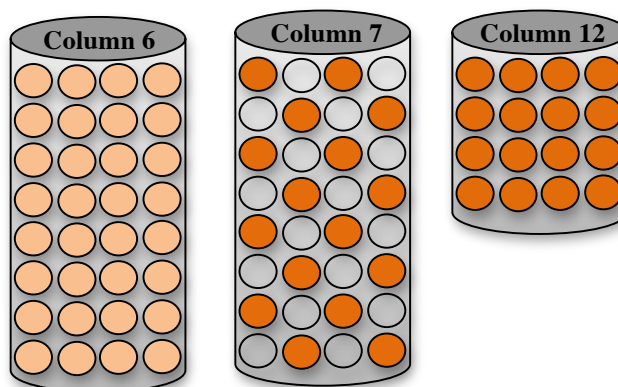

Figure 3.25.: Model for the compared columns in terms of SO density distribution and column dimensions; light orange: 232 $\mu\text{mol/g}$ (DHQD-type SO₄); dark orange: 490 $\mu\text{mol/g}$ (DHQD-type SO₄); colorless: AzP-Silica particles.

Column 7 and 12 behave more similar to each other compared to column 6, which behaves a bit different. For the aminosulfonic acids retention time t_1 is significantly higher, as well as for the aminophosphonates. The same results were observed for the retention times of the second eluted enantiomer (not shown here, for the data see **appendix**).

There was no separation observed for PFB-Leu and DNB-*N*-methyl leucine for columns 7 and 12. On the other hand, PFB-Leu was partially separated on column 6 ($\alpha = 1.09$). The retention factors (see **figure 3.27.**) are comparable but slightly lower for most of the SAs for column 7 compared to column 6. This reflects the expectation. The CSP in column 7 is a physical mixture prepared from CSP4 and pure AzP-Silica to give an average SO density of 238 $\mu\text{mol/g}$. The distribution of the SO density is locally inhomogeneous. **Figure 3.25.** can be seen as a model for the SO density distribution.

As one can imagine, the retention strength along the column is always the same for column 6 and 12 because of homogeneous SO-concentration along the whole column.

Figure 3.26.: Comparison of the retention times of the first eluted enantiomer; flow rate always 1.0 mL/min; column 6: DHQD-type, 232 $\mu\text{mol/g}$; column 7: DHQD-type, 238 $\mu\text{mol/g}$; column 12: DHQD-type, 490 $\mu\text{mol/g}$.

The different properties are also reflected in the selectivity coefficient α , the resolution R and the average number of theoretical separation plates N_{av} . For this comparative purpose the flow rates are different to ensure a fair comparison. The flow rate for the two 150 mm long columns is 1.0 mL/min in comparison to the half of the flow rate (0.5 mL/min) for the column with the half of the length (75 mm). The selectivity coefficients are comparable for the high loaded short column 12 and the physical mixture CSP in column 7 with the same total amount of SO (see **figure 3.28.**).

There was no separation observed for PFB-Leu and DNB-N-Me-Leu both for columns 7 and 12, as already mentioned above.

Figure 3.27.: Comparison of the retention factors k_1 ; flow rate for columns 6 and 7: 1.0 mL/min.; column 6: DHQD-type, 232 $\mu\text{mol/g}$; column 7: DHQD-type, 238 $\mu\text{mol/g}$.

Figure 3.28.: Comparison of the selectivity coefficients; flow rate for columns 6 and 7 1.0 mL/min, for column 12 0.5 mL/min.; column 6: DHQD-type, 232 $\mu\text{mol/g}$; column 7: DHQD-type, 238 $\mu\text{mol/g}$; column 12: DHQD-type, 490 $\mu\text{mol/g}$.

The resolution R for column 6 is always higher compared to 7 and 12 (see **figure 3.29.**). Columns 7 and 12 are – in terms of resolution – more similar. This leads to the conclusion that a high-loaded CSP like in the case of the 75x4 mm ID column 12 (490 $\mu\text{mol/g}$) is not as efficient as a middle-loaded CSP like in the case of column 6 (150x4 mm ID, 232 $\mu\text{mol/g}$). They both include the same total amount of SO, but the average efficiency is almost doubled (factor of 1.9) for column 6 in comparison to column 12. The difference between column 6 and 7 is even higher (average factor of 2.3 in terms of resolution).

Figure 3.29.: Comparison of the resolution; flow rate for columns 6 and 7 1.0 mL/min, for column 12 0.5 mL/min.; column 6: DHQD-type, 232 $\mu\text{mol/g}$; column 7: DHQD-type, 238 $\mu\text{mol/g}$; column 12: DHQD-type, 490 $\mu\text{mol/g}$.

The average numbers of theoretical plates N_{av} are compared in **figure 3.30**.. One can clearly see that in the case of column 6 the number of theoretical plates is higher in comparison to the two other columns. Columns 7 and 12 do have almost the same number of theoretical plates ($N_{av} = 1473$ and 1443 , $n = 20$, all measured compounds). Compared to column 6 N_{av} (4691 , $n = 67$, all measured compounds) is decreased for both of them by an average factor of 3.2.

Figure 3.30.: Comparison of average number of theoretical plates N_{av} ; flow rate for columns 6 and 7 1.0 mL/min, for column 12 0.5 mL/min.; column 6: DHQD-type, 232 $\mu\text{mol/g}$; column 7: DHQD-type, 238 $\mu\text{mol/g}$; column 12: DHQD-type, 490 $\mu\text{mol/g}$.

3.13. Effects of different SO loading

Because a large number of CSPs with different SO loading was prepared, it was possible to determine the effect of SO loading with regards to retention, selectivity, resolution and efficiency. The columns used for this study were all packed with DHQD-type CSPs based on the same SO (SO₄), but with different SO density on the surface. In **table 3.3.** a summary of all used columns for determining the effects of different SO loading including their properties is given.

Table 3.3.: Summary of all used columns for determining the effects of different SO loading (all SOs DHQD-type).

| Column Number | CSP Number | Type of SO | Dimensions of the columns | Dimensions of Silica | SO loading [$\mu\text{mol/g}$] |
|---------------|------------|-----------------|---------------------------|------------------------------------|----------------------------------|
| 4 | CSP4 | SO ₄ | 150x4 mm ID | 5 μm , 120 \AA | 490 |
| 8 | CSP8 | | | | 314 |
| 6 | CSP6 | | | | 232 |
| 9 | CSP9 | | | | 150 |

Of course retention time and k -values are increasing with higher SO loading as depicted in **figure 3.31.** (see below). An almost linear relationship for example was observed for the aminosulfonic acid derivative P-DML-ACHSA. CSP8 with 314 $\mu\text{mol/g}$ slightly differs from the other CSPs in terms of k -values.

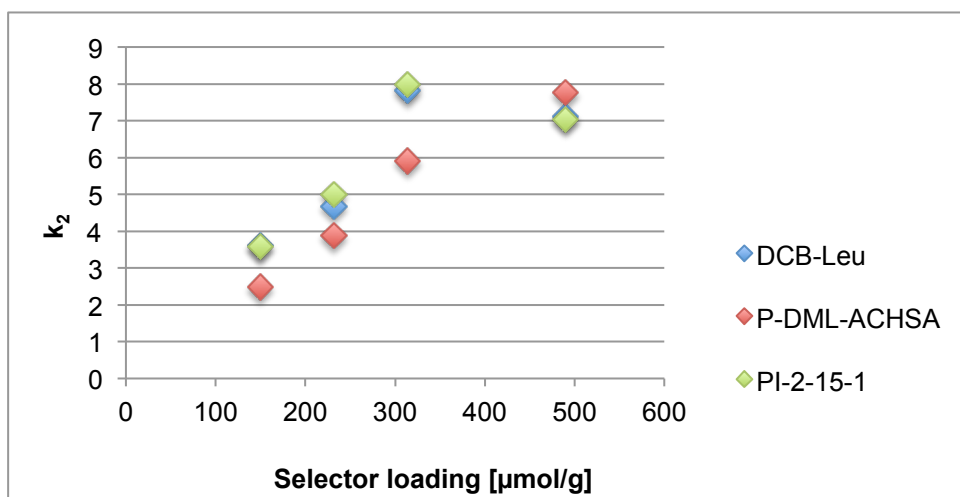

Figure 3.31.: Dependency of k_2 of the SO loading (DHQD-type).

In **figure 3.32.** a more detailed diagram of the k_2 dependency on the SO loading for *N*-protected amino acid derivatives is shown. The overall effect of increasing retention factors among higher SO loading was observed for every single acidic SA, including *N*-protected aminosulfonic acids, carboxylic acids and *N*-protected aminophosphonates.

Figure 3.32.: Dependency of k_2 of the SO loading (DHQD-type) shown for a series of *N*-protected amino acid derivatives.

A different behavior was observed for the selectivity coefficient alpha. The selectivity drops with increasing SO loading for every single acidic SA. This trend is close to linear behavior.

Figure 3.33.: Dependency of the selectivity of the SO loading (DHQD-type).

The corresponding resolution has a maximum value at a SO loading of 314 $\mu\text{mol/g}$, higher loading results in rapid loss of resolution. This result indicates a blockage of the silica pores due to high SO loading which leads to the limited conformational freedom of the immobilized SOs, and thus hindered interactions with SAs. Before this threshold of about 310 $\mu\text{mol/g}$ the resolution-values increase with increasing SO loading. A SO concentration of about 310 $\mu\text{mol/g}$ seems to be an optimal coverage.

Figure 3.34.: Dependency of the resolution of the SO loading (DHQD-type).

Exactly the same behavior was observed for the resolution-dependent number of theoretical plates for separation. After exceeding the limit value at 314 $\mu\text{mol/g}$ N drops rapidly and efficiency is actually decreased below the value obtained for a SO loading of 150 $\mu\text{mol/g}$.

Figure 3.35.: Dependency of the number of theoretical plates of the SO loading (DHQD-type).

Since a lower loading also results in higher selectivity values and lower retention times, a quite low selector-loaded CSP (e.g. 150 $\mu\text{mol/g}$) has to be preferred relative to a CSP with saturated SO density, which of course is more economic as well.

3.14. Comparison of Column 8 to QD-AX

Regarding the effects of different SO loading column 8 is well suited for a comparison to the standard QD-AX CSP packed column 14. Both these columns are quinidine derived CSPs and contain a similar amount of immobilized SO per gram silica (column 8 314 $\mu\text{mol/g}$; column 14 app. 340 $\mu\text{mol/g}$). The QD-AX SO has been immobilized via radical thiol alkene addition using the vinyl residue at position 3 of the quinuclidine ring as immobilizing anchor. The two CSPs are therefore not only different in the structure of the SO, but also immobilized via different immobilization strategies at different positions, because CSP8 in column 8 has been immobilized via Huisgen alkyne-azide click chemistry with the propargyl moiety of the aromatic linker as an immobilizing anchor. For the structure of the CSP in column 14 see **figure 3.1.**, the structure of CSP8 is shown in the experimental part of the thesis.

Figure 3.36.: Comparison of the selectivities of column 8 and column 14; column 8: DHQD-type, 314 $\mu\text{mol/g}$; column 14: QD-AX type, app. 340 $\mu\text{mol/g}$.

Figure 3.37.: Comparison of the resolution-values of column 8 and column 14; column 8: DHQD-type, 314 $\mu\text{mol/g}$; column 14: QD-AX type, app. 340 $\mu\text{mol/g}$.

First of all, the two columns differ in the general separation capability for chiral acidic compounds. DNB-Pro was not separated on QD-AX, whereas flurbiprofen was not separated on column 8 under the given mobile phase composition. All the other samples shown in **figure 3.36.** and **3.37.** were at least partially separated.

The alpha-values obtained with QD-AX are generally higher compared to column 8. The difference for example for DCB-Leu is striking, also for the two aminosulfonic acids P-DML-ACHSA and P-DCL-ACHSA. The same results were observed in terms of resolution. Solvophobic effects and different binding increments in terms of relative strength and position could make the difference in this case.

One exception is DBTAMME (dibenzoyltartaric acid monomethyl ester), where the behavior is exactly the opposite.

3.15. Loading Study

The loadability of the highest-loaded CSP in terms of a possible preparative application was another topic for the evaluation. Therefore an SA that meets several criteria has to be used:

- Solubility in methanol or mobile phase should be high.
- Retention time should be short.

- Selectivity coefficient and resolution-value should be reasonably large.
- The SA must be available in larger quantities than analytical amounts.

This loading study was performed with racemic Ac-Phe as an SA of choice. Ac-Phe was not the SA with the best prerequisites, but it was a compromise between all the criteria. In order to avoid long retention time a 75x4 mm ID column with 490 $\mu\text{mol/g}$ SO loading (CSP4, column 12) and a SA solution with a concentration of 100 mg/mL in MeOH were used. Further chromatographic conditions that were used were 0.5 mL/min flow rate, 15 min run time and a detection wavelength of 270 nm.

Figure 3.38.: Absorption spectra of Ac-Phe.

The wavelength was chosen higher than the usual 254 nm for screening, because sensitivity is lower and therefore the detector does not reach its limit at higher concentrations. In **figure 3.38.** an absorption spectrum of Ac-Phe from 210 to 310 nm is shown. As an initial mobile phase the same phase composition as used for screening was applied (MeOH/AcOH/NH₄OAc 99/1/0.25 v/v/w).

Figure 3.39.: Chromatogram for Ac-Phe ($\alpha = 1.37$); column 12 (75x4 mm ID, 490 $\mu\text{mol/g}$, DHQD-type CSP); injection volume: 5 μL (= 0.5 mg); sample concentration: 100 mg/mL Ac-Phe in MeOH; flow rate: 0.5 mL/min; detection wavelength: 270 nm; mobile phase composition: MeOH/AcOH/NH₄OAc 99/1/0.25 (v/v/w); temperature: 25°C.

Figure 3.40.: Chromatogram for Ac-Phe ($\alpha = 1.58$); column 15 (75x4 mm ID, app. 340 $\mu\text{mol/g}$, QD-AX type CSP); injection volume: 5 μL (= 0.5 mg); sample concentration: 100 mg/mL Ac-Phe in MeOH; flow rate: 0.5 mL/min; detection wavelength: 270 nm; mobile phase composition: MeOH/AcOH/NH₄OAc 99/1/0.25 (v/v/w); temperature: 25°C.

In **figure 3.39**, one chromatogram for a 5 μL injection volume (0.5 mg total amount of injected SA) is shown. Retention time is 6.26 min for the first eluted enantiomer (*L*) and 8.05 min for the second eluted enantiomer (*D*) at a void time of 1.46 min; selectivity coefficient of 1.37 and a resolution of 1.96. Both enantiomers are baseline separated according to the chromatogram.

For comparative purposes another loading study was carried out with a 75x4 mm ID standard QD-AX column (column 15). For a better comparison of the two columns, retention time for QD-AX had to be adjusted and therefore extended, because it was not the same as for column 12 (see **figure 3.40**). It was easily possible to adjust the k_2 -value via modification of the buffer concentration (counter-ion concentration) by diluting the standard mobile phase with pure MeOH [67]. This behavior follows the well-established stoichiometric displacement model [13, 78].

Alternative possibilities would be to vary the flow rate, pH-value, temperature and the content of organic modifier like ACN. In previous studies by Mandl et al. it has been shown that according to an anion-exchange mechanism the retention times are decreasing with increasing buffer salt concentration in the mobile phase [50]. However, enantioselectivity remains almost constant and therefore it is not significantly affected by the buffer concentration [13].

Table 3.4.: Adjustment of k_2 by variation of the buffer concentration.

| k_2 | $\log(k_2)$ | Bufferconc. [%] | $\log(1/\text{Bufferconc.})$ |
|-------|-------------|-----------------|------------------------------|
| 5.762 | 0.761 | 0.250 | 0.602 |
| 7.706 | 0.887 | 0.125 | 0.903 |
| 9.841 | 0.993 | 0.063 | 1.204 |
| 8.049 | 0.906 | 0.107 | 0.971 |

In **figure 3.41.** and **table 3.4.** the results for the adjustment of the buffer concentration are shown. Using the linear equation it was easily possible to adjust the k_2 -value for column 15 (QD-AX type) without a significant loss of enantioselectivity. In reality the adjusted k_2 -value was slightly higher than the calculated k_2 -value, because the mobile phase was freshly prepared and not diluted from the concentrated version used for the mobile phase variation.

Figure 3.41.: Linear correlation between $\log(k_2)$ vs. $\log(\text{bufferconcentration}^{-1})$; column 15: QD-AX type, app. 340 $\mu\text{mol/g}$.

In **figure 3.42.** one can see the overlaid chromatograms for column 12. The retention is shifted to lower retention times the higher the amount of injected sample is, because the higher retained enantiomer (Ac-D-Phe) acts as a displacer for the lower retained enantiomer (Ac-L-Phe). Furthermore, overloading-effects of the column are involved in the retention.

Figure 3.42.: Overlaid chromatograms for Ac-Phe; column 12 (75x4 mm ID, 490 $\mu\text{mol/g}$, DHQD-type CSP); injection volume: 5-100 μL (0.5-10 mg); sample concentration: 100 mg/mL Ac-Phe in MeOH; flow rate: 0.5 mL/min; detection wavelength: 270 nm; mobile phase composition: MeOH/AcOH/ NH_4OAc 99/1/0.25 (v/v/w); temperature: 25°C.

The selectivity is almost constant (column 12 $\alpha_{av} = 1.36$, $n = 9$; QD-AX $\alpha_{av} = 1.57$, $n = 12$), as well as the end of the second peak at about 10 minutes. The resolution and plate numbers are of course decreasing rapidly with higher amount of injected sample (data not shown here, see **appendix**). In **figure 3.43**, the overlaid chromatograms for QD-AX column 15 are shown. One can clearly see that the sample contains impurities, which are retained exactly in between the two enantiomers of Ac-Phe. However, for a possible preparative purpose this would not be a problem because one can easily cut impurity-containing fractions out of the fractions with the pure enantiomer as the product.

With the assumption that approximately 0.7 g of CSP are packed in a 75x4 mm ID column, the calculated theoretical productivity for column 12 is about 0.4 kg pure enantiomer per kg CSP per day. For QD-AX the productivity is about 0.6 kg/kg/day, so 50% higher. Please note that the selectivity coefficient for the separation on QD-QX is higher in comparison to column 12 (see above), so therefore the productivity has to be better.

The calculated productivities are just approximate calculations for one mobile phase system. There are many parameters, which can be optimized to achieve higher productivities.

Figure 3.43.: Overlaid chromatograms for Ac-Phe; column 15 (75x4 mm ID, app. 340 $\mu\text{mol/g}$, QD-AX type CSP); injection volume: 5-100 μL (0.5-10 mg); sample concentration: 100 mg/mL Ac-Phe in MeOH; flow rate: 0.5 mL/min; detection wavelength: 270 nm; mobile phase composition: MeOH/AcOH/NH₄OAc 99.46/0.43/0.11 (v/v/w); temperature: 25°C.

4. Experimental Part

4.1. Materials and Methods

¹H-NMR and ¹³C-NMR spectra were measured with a Bruker DRX 400 spectrometer (Karlsruhe, Germany) at 400 MHz and 100 MHz, respectively, at room temperature. Either CDCl₃ or CD₃OD (both 99.8%, Deutero GmbH, Kastellaun, Germany) were used as solvents and the solvent signals were used as reference signals. The raw data were processed with SpinWorks 2.5 software.

The IR-measurements were carried out on a Bruker Tensor 27 Diamond ATR FTIR spectrometer (Ettlingen, Germany) with Opus 4.2 software.

Mass spectrometric measurements of the selectors (SOs) were performed using a 4000 QqLIT mass spectrometer with an ESI ion source from Applied Biosystems (Foster City, USA). All mass spectrometric measurements were carried out in positive ionization mode. For data processing the software Analyst 1.5 was used. The mass spectrometer was coupled with a 1200 series HPLC system from Agilent Technologies (Santa Clara, USA). The chromatographic runs for LC/MS were done using reversed phase mode chromatography.

CHNS elemental analyses of the CSPs were operated on a EURO EA 3000 CHNS-O instrument from HEKAtech (Wegberg, Germany). Determination of the chlorine content of the CSPs was performed using potentiometric titration with a Mettler DL 21 titrator (Greifensee, Switzerland).

For thin layer chromatography TLC Silica gel 60 F₂₅₄ from Merck was used. Flash column chromatography was carried out using Normasil 60 Silica Gel from VWR. Daisogel SP-120-5P from Daiso (Japan) was used as a basis for AzP-Silica and MP-Silica (both 5 μm, 120 Å). MP-Silica was prepared by modification and endcapping in house.

The solvents for synthesis were purchased from VWR, ROTH, DonauChem, Sigma-Aldrich, Merck and FLUKA. As reagents and catalysts the following chemicals were used: 3,5-dichloro-4-hydroxybenzoic acid (97%, Sigma-Aldrich), allyl bromide (99%, Aldrich), propargyl bromide (80% in toluene, FLUKA), (COCl)₂ (98%, Aldrich), anhydrous DMF (99.8%, Sigma-Aldrich), NaN₃ (>99%, Aldrich), DHQN and DHQD.HCl (both >97%, Buchler), dibutyltin dilaurate (95%, Aldrich), AIBN (≥98%, Merck), p-toluenesulfonic acid monohydrate (98.5%, Sigma-Aldrich), 3-chloropropyl-

trimethoxysilane (97%, ABCR), tetrabutylammonium iodide (98%, Merck), diisopropylethylamine (98%, FLUKA), CuI (98%, Aldrich), EDTA disodium salt (99%, FLUKA) and propargyl alcohol (99%, AcrosOrganics).

As mobile phase compounds the following chemicals were used: MeOH (HPLC grade quality, 99.8%, VWR), AcOH ($\geq 99\%$, Sigma-Aldrich) and NH_4OAc ($\geq 97\%$, p.a., Fluka).

4.2. Synthesis of Linker 1

4-Allyloxy-3,5-dichlorobenzoic acid allyl ester (2a)

33.88 g of 3,5-dichloro-4-hydroxybenzoic acid **1** (158.8 mmol), 32 mL allyl bromide (369.8 mmol) and 64.85 g of potassium carbonate (447.5 mmol) were suspended in 300 mL of acetone and refluxed for 16 h. The orange suspension was cooled to room temperature and poured into 600 mL of water. After extraction with EtOAc (3x100 mL), the combined organic phases were washed with 100 mL of H_2O and 50 mL of saturated aqueous NaCl solution. The combined organic solution was dried with anhydrous MgSO_4 , filtered and evaporated under reduced pressure. The obtained orange crude 4-allyloxy-3,5-dichlorobenzoic acid allyl ester was then purified by flash column chromatography on silica (250 g of silica, PE/EtOAc 20:1). The fractions with pure intermediate (control on TLC with the same mobile phase as used for flash column chromatography) were collected, filtered and evaporated under reduced pressure.

Yield: 40.55 g (141.2 mmol, 89%) of a colorless transparent oil.

$^1\text{H-NMR}$ [CD_3OD]: δ = 7.87 (s, 2H), 6.03 (m, 1H), 5.94 (m, 1H), 5.32 (m, 2H), 5.19 (m, 2H), 4.72 (m, 2H), 4.54 (m, 2H).

$^{13}\text{C-NMR}$ [CD_3OD]: δ = 172.6 (C=O), 154.1 ($\text{C}_{\text{ar}}\text{-O}$), 134.7 ($\text{C}_{\text{ar}}\text{Cl}$), 134.3 ($\text{C}_{\text{ar}}\text{H}$), 131.6 (CH), 131.6 (CH), 130.4 (C_{ar}), 120.7 ($\text{CH}_2\text{=}$), 120.4 ($\text{CH}_2\text{=}$), 76.3 (CH_2), 68.0 (CH_2).

IR: 3074 cm^{-1} ($\nu\text{=CH}_2$), 1719 cm^{-1} ($\nu\text{C=O}$).

4-Allyloxy-3,5-dichlorobenzoic acid (3a)

The 4-allyloxy-3,5-dichlorobenzoic acid allyl ester **2a** (40.55 g, 141.2 mmol) was diluted with 60 mL of EtOH and a solution of 12.15 g NaOH (303.8 mmol) in 60 mL H_2O was added. The reaction mixture was refluxed for 1 h. After cooling to 0°C the

orange-brown solution was diluted with 30 mL EtOH and 50 mL of H₂O. After acidification with concentrated HCl to pH~2 the 4-allyloxy-3,5-dichlorobenzoic acid **3a** immediately precipitated as a white solid. The suspension was filtered, the filtration cake was washed with cold H₂O (2x100 mL) and afterwards dried under reduced pressure at 60°C for 48 h.

Yield: 34.80 g (140.9 mmol, quantitative yield) of a white solid.

¹H-NMR [CD₃OD]: δ = 7.97 (s, 2H), 6.15 (m, 1H), 5.35 (dd, 2H), 4.89 (s, 1H), 4.64 (d, 2H).

¹³C-NMR [CD₃OD]: δ = 167.7 (C=O), 156.5 (C_{ar}-O), 134.5 (C_{ar}H), 131.8 (CH), 131.3 (C_{ar}Cl), 130.0 (C_{ar}), 119.7 (CH₂=), 76.0 (CH₂).

IR: 3077 cm⁻¹ (ν=CH₂), 1690 cm⁻¹ (νC=O).

4-Allyloxy-3,5-dichlorobenzoyl chloride (**4a**)

Dry 4-allyloxy-3,5-dichlorobenzoic acid **3a** (10.83 g, 43.8 mmol) was slowly suspended in 50 mL of (COCl)₂ and four drops of dry DMF as a catalyst were added slowly. The suspension was refluxed for 1 h while it turned into an orange clear solution with a small amount of brown precipitate. The main part of unreacted oxalyl chloride was distilled off and 70 mL of petroleum ether (PE) were added to the reaction mixture together with a spatula tip of activated carbon (app. 200 mg) for adsorption of side products and impurities. After refluxing for three min the still boiling reaction mixture was filtered and evaporated under reduced pressure. No further purification was carried out. Characterization of the product by NMR and IR spectroscopy was not carried out, because the product is not very stable and therefore it was directly converted into the corresponding acyl azide.

Yield: 11.04 g (41.6 mmol, 95%) of an orange-brown liquid acyl halide.

4-Allyloxy-3,5-dichlorobenzoyl azide (**5a**)

The acyl halide **4a** (11.04 g, 41.6 mmol) was dissolved in 70 mL of cold acetone and cooled to 0°C. A solution of 12.55 g NaN₃ (193.0 mmol) in 40 mL of H₂O was then added dropwise to the acyl halide solution under vigorous stirring during 1 h at 0°C. After a while a white precipitate appeared in the red-brown solution. The reaction mixture was then diluted with 100 mL of water and extracted with EtOAc (3x75 mL). The combined organic phases were washed with 30 mL of saturated aqueous NaCl

solution, dried with MgSO₄, filtered and evaporated under reduced pressure at room temperature. No further purification was carried out.

Yield: 9.83 g (36.1 mmol, 87%) of an orange-brown oil.

¹H-NMR [CD₃OD]: δ = 7.88 (d, 2H), 6.05 (m, 1H), 5.35 (d, 1H), 5.23 (d, 1H), 4.57 (d, 2H).

¹³C-NMR [CD₃OD]: δ = 170.4 (C=O), 156.2 (C_{ar}-O), 132.8 (C_{ar}H), 130.6 (C_{ar}Cl), 130.4 (CH), 127.9 (C_{ar}), 119.9 (CH₂=), 75.1 (CH₂).

IR: 3073 cm⁻¹ (ν=CH₂), 2162 cm⁻¹ (νN₃), 1686 cm⁻¹ (νC=O).

4-Allyloxy-3,5-dichlorophenylisocyanate (L1)

The last step of the synthesis of **L1** was the formation of isocyanate via Curtius-rearrangement of the acyl azide. The acyl azide **5a** (9.83 g, 36.1 mmol) was dissolved in 100 mL of azeotropically dried toluene and refluxed for 3h. Emerging nitrogen indicated the successful rearrangement. After 3 h no nitrogen bubbles were visible in the bubble counter, so the reaction was completed. After evaporation of the solvent under reduced pressure, the transparent liquid isocyanate **L1** was obtained by vacuum distillation (boiling point: 99°C at 0.10 mbar). The purified liquid product was stored in the freezer with air-exclusion, because the isocyanate is highly water sensitive.

Yield: 7.22 g (29.6 mmol, 82%) of a colorless liquid **L1**.

¹H-NMR [CDCl₃]: δ = 6.90 (s, 2H), 5.97 (m, 1H), 5.20 (dd, 2H), 4.39 (d, 2H).

¹³C-NMR [CDCl₃]: δ = 149.7 (C_{ar}-O), 133.0 (CH), 130.6 (C_{ar}Cl), 130.5 (C_{ar}), 125.4 (C_{ar}H), 119.6 (CH₂=), 74.9 (CH₂).

IR: 2250 cm⁻¹ (νN=C=O).

4.3. Synthesis of Linker 2

3,5-Dichloro-4-propargyloxybenzoic acid propargyl ester (2b)

7.29 g of 3,5-dichloro-4-hydroxybenzoic acid **1** (34.2 mmol), 15.35 mL of propargyl bromide (80% in toluene, 118.7 mmol) and 8.35 g of potassium carbonate (60.4 mmol) were suspended in 40 mL of DMF and heated up to 60°C for 18 h. The orange-brown suspension was cooled to room temperature and poured into 150 mL of water. After extraction with EtOAc (3x75 mL), the combined organic phases were washed with 50 mL of H₂O and 30 mL of saturated aqueous NaCl solution. The

combined organic solution was dried with MgSO_4 , filtered and evaporated under reduced pressure. The obtained orange-brown solid crude product was then purified by flash column chromatography on silica (150 g of silica, CH_2Cl_2 as a mobile phase for flash column chromatography and fraction control on TLC). The fractions with pure intermediate were collected, filtered and evaporated under reduced pressure.

Yield: 9.23 g (32.6 mmol, 95%) of a white solid.

$^1\text{H-NMR}$ [CDCl_3]: δ = 8.02 (s, 2H), 4.89 (dd, 4H), 2.54 (t, 2H).

$^{13}\text{C-NMR}$ [CDCl_3]: δ = 163.7 (C=O), 154.5 ($\text{C}_{\text{ar-O}}$), 130.8 (C_{arCl}), 130.7 (C_{arH}), 127.5 (C_{ar}), 77.7 (C_4), 76.0 (CH), 61.0 (CH_2), 53.5 (CH_2).

IR: 3298 cm^{-1} ($\nu\equiv\text{CH}$), 3257 cm^{-1} ($\nu\equiv\text{CH}$), 2125 cm^{-1} ($\nu\text{C}\equiv\text{C}$), 1710 cm^{-1} ($\nu\text{C}=\text{O}$).

3,5-Dichloro-4-propargyloxybenzoic acid (3b)

The 3,5-dichloro-4-propargyloxybenzoic acid propargyl ester **2b** (9.23 g, 32.6 mmol) was dissolved in 70 mL of EtOH and a solution of 2.94 g NaOH (73.5 mmol) in 40 mL H_2O was added. The reaction mixture was refluxed for 1 h. The yellowish clear solution was diluted with 20 mL of EtOH and 20 mL of H_2O and cooled down to 0°C with an ice-bath. After acidification with concentrated HCl to pH~2, the 3,5-dichloro-4-propargyloxybenzoic acid immediately precipitated as a white solid. The suspension was filtered and the filtration cake was washed with 2x100 mL of cold H_2O and afterwards dried under reduced pressure at 60°C for 48 h.

Yield: 7.30 g (29.8 mmol, 91%) of a white solid.

$^1\text{H-NMR}$ [$\text{CD}_3\text{OD}+\text{CDCl}_3$]: δ = 7.97 (s, 2H), 4.85 (d, 2H), 2.79 (t, 1H).

$^{13}\text{C-NMR}$ [$\text{CD}_3\text{OD}+\text{CDCl}_3$]: δ = 166.2 (C=O), 153.9 ($\text{C}_{\text{ar-O}}$), 130.6 (C_{arH}), 130.3 (C_{arCl}), 129.0 (C_{ar}), 78.2 (CH), 77.9 (C_4), 60.9 (CH_2).

IR: 3294 cm^{-1} ($\nu\equiv\text{CH}$), 2131 cm^{-1} ($\nu\text{C}\equiv\text{C}$), 1698 cm^{-1} ($\nu\text{C}=\text{O}$).

3,5-Dichloro-4-propargyloxybenzoyl chloride (4b)

7.30 g of the acid **3b** (29.8 mmol) were slowly suspended in 50 mL of $(\text{COCl})_2$ at 0°C and four drops of dry DMF as a catalyst were added slowly. The suspension was stirred at 0°C for 15 min and then heated up to 30°C for 45 min. The suspension turned into a yellowish clear solution with little brown drops. The bulk of unreacted oxalyl chloride was then distilled off and 120 mL of PE were added to the reaction mixture together with a spatula tip of activated carbon (app. 200 mg) for adsorption of side products and impurities. After refluxing for 3 min the still boiling reaction

mixture was filtered and evaporated under reduced pressure. No further purification was carried out. Characterization of the product by NMR and IR spectroscopy was not carried out, because the product is not very stable. The acyl chloride was then directly converted into acyl azide.

Yield: 7.16 g (27.2 mmol, 91%) of a slightly yellowish solid acyl halide.

3,5-Dichloro-4-propargyloxybenzoyl azide (**5b**)

7.16 g of the acyl chloride **4b** (27.2 mmol) were dissolved in 70 mL of cold acetone and cooled to 0°C with an ice-bath. A solution of 5.48 g NaN₃ (84.3 mmol) in 30 mL of H₂O was then added dropwise to the acyl halide solution under vigorous stirring during 1 h at 0°C. After a while a voluminous white precipitate appeared in the orange solution. The precipitate was filtered and washed with cold H₂O (2x50 mL). For an effective drying the filtration cake was dissolved in 150 mL of EtOAc and the organic solution was washed with 20 mL of H₂O, 20 mL of saturated aqueous NaCl solution and afterwards dried with anhydrous MgSO₄. Evaporation of the solvent and drying under vacuum at room temperature yielded a fully dry product.

Yield: 6.43 g (23.8 mmol, 88%) of a white solid.

¹H-NMR [CDCl₃]: δ = 7.91 (s, 2H), 4.81 (d, 2H), 2.47 (t, 1H).

¹³C-NMR [CDCl₃]: δ = 170.3 (C=O), 155.2 (C_{ar}-O), 130.9 (C_{ar}Cl), 130.4 (C_{ar}H), 128.6 (C_{ar}), 77.7 (CH), 77.0 (C₄), 61.1 (CH₂).

IR: 3297 cm⁻¹ (ν≡CH), 2166 cm⁻¹ (νN₃), 1686 cm⁻¹ (νC=O).

3,5-Dichloro-4-propargyloxyphenylisocyanate (**L2**)

5.21 g of the acyl azide **5b** (19.3 mmol) were dissolved in 200 mL of azeotropically dried toluene and refluxed for 3 h. After evaporation of the solvent under reduced pressure a white solid was obtained by vacuum distillation, but implementation of the distillation was difficult and only 1.41 g of **L2** (5.8 mmol, 30%) could be isolated.

Therefore the formation of **L2** was carried out in azeotropically dried toluene as described above. The reaction solution was then cooled to room temperature and **L2** was directly used *in solution* without further purification, because isolation by vacuum distillation resulted in large losses of the product.

¹H-NMR [CDCl₃]: δ = 7.10 (s, 1H), 6.91 (s, 1H), 4.60 (dd, 2H), 2.37 (m, 1H).

¹³C-NMR [CDCl₃]: δ = 125.4 (C_{ar}Cl), 119.2 (C_{ar}), 76.6 (C₄), 61.0 (CH), 53.1 (CH₂).

IR: 3294 cm⁻¹ (ν≡CH), 2263 cm⁻¹ (νN=C=O).

4.4. Synthesis of Selector 1

9-(4-Allyloxy-3,5-dichlorophenylcarbamoyl) dihydroquinine (SO1)

1.84 g of commercially available DHQN (5.6 mmol) were dissolved in 100 mL of toluene. After flushing the apparatus with nitrogen, 50 mL of toluene were distilled off under nitrogen atmosphere. After finishing the drying process 1.51 g of **L1** (6.2 mmol) and 40 μ L of DBTDL as a catalyst were added with nitrogen flushing of the apparatus. The reaction mixture was refluxed for 16 h. Due to several by-products visible on TLC the clear brownish solution was evaporated to dryness and the crude product was purified by flash column chromatography on silica (150 g of silica, $\text{CH}_2\text{Cl}_2/\text{MeOH}$ 10:1). The fractions with pure product (monitored by TLC using the same eluent) were collected, filtered and evaporated under reduced pressure. The obtained solid was dried under vacuum at room temperature.

Yield: 2.85 g (5.0 mmol, 89%) of a white solid.

$^1\text{H-NMR}$ [CDCl_3]: δ = 8.67 (d, 1H), 7.99 (d, 1H), 7.48 (d, 1H), 7.35 (d, 1H), 7.33 (s, 2H), 7.26 (d, 1H), 6.54 (d, 1H), 6.11 (m, 1H), 5.38 (dd, 1H), 5.25 (dd, 1H), 4.49 (d, 2H), 3.96 (s, 3H), 3.34 (q, 1H), 3.15-2.95 (broad, 2H), 2.63 (m, 1H), 2.36 (d, 1H), 1.89-1.78 (broad, 2H), 1.77-1.64 (broad, 1H), 1.59-1.39 (broad, 3H), 1.39-1.22 (broad, 2H), 0.86 (t, 3H).

$^{13}\text{C-NMR}$ [CDCl_3]: δ = 158.6 ($\text{C}_{\text{ar}}\text{-O}$), 152.4 ($\text{C}=\text{O}$), 147.3 ($\text{C}_{\text{ar}}\text{H}$), 144.7 (C_{ar}), 143.4 (C_{ar}), 134.4 (C_{ar}), 132.9 ($\text{CH}=\text{}$), 131.7 ($\text{C}_{\text{ar}}\text{H}$), 129.7 (C_{ar}), 127.2 (C_{ar}), 121.9 ($\text{C}_{\text{ar}}\text{H}$), 118.8 ($\text{CH}_2=\text{}$), 118.8 ($\text{C}_{\text{ar}}\text{H}$), 118.7 ($\text{C}_{\text{ar}}\text{H}$), 101.4 ($\text{C}_{\text{ar}}\text{H}$), 74.4 (CH), 74.4 (CH_2), 58.9 (CH), 58.0 (CH_2), 55.7 ($\text{CH}_3\text{-O}$), 42.6 (CH_2), 37.3 (CH), 28.3 (CH_2), 27.7 (CH_2), 25.2 (CH), 24.2 (CH_2), 12.1 (CH_3).

IR: 2930 cm^{-1} , 2865 cm^{-1} , 1730 cm^{-1} ($\nu\text{C}=\text{O}$).

MS [ESI, positive]: 570 [$\text{M}+\text{H}$] $^+$, 286 [$\text{M}+2\text{H}$] $^{2+}$.

4.5. Synthesis of Selector 2

DHQD free base

5.0 g of commercially available DHQD.HCl (13.8 mmol) were dissolved in 800 mL of H_2O and alkalinized with NaHCO_3 to pH 8. The solution was stirred for 18 h at 50°C. DHQD as free base was extracted with CH_2Cl_2 (3x75 mL) and the combined organic phases were washed with 30 mL of H_2O and 30 mL of saturated aqueous NaCl

solution. After drying with MgSO_4 the solvent was evaporated. The obtained white crystals were dried under vacuum for 24 h.

Yield: 4.50 g (quantitative yield).

9-(4-Allyloxy-3,5-dichlorophenylcarbamoyl)dihydroquinidine (SO2)

1.88 g of DHQD free base (5.8 mmol) were suspended in 100 mL of toluene. After flushing the apparatus with nitrogen 50 mL of toluene were distilled off under nitrogen atmosphere. After finishing the drying process 1.61 g of **L1** (6.7 mmol) and 40 μL of DBTDL as a catalyst were added. The reaction mixture was then refluxed for 16 h. Due to several by-products visible on TLC the clear brownish solution was evaporated to dryness and the crude product was purified by flash column chromatography on silica (150 g of silica, $\text{CH}_2\text{Cl}_2/\text{MeOH}$ 10:1). The fractions with pure product monitored by TLC were collected, filtered and evaporated under reduced pressure. The obtained crystals were dried under vacuum.

Yield: 2.12 g (3.7 mmol, 64%) of a white solid.

$^1\text{H-NMR}$ [CDCl_3]: δ = 8.70 (d, 1H), 8.01 (d, 1H), 7.48 (d, 1H), 7.38 (s, 2H), 7.36 (d, 1H), 7.32 (d, 1H), 6.54 (d, 1H), 6.13 (m, 1H), 5.40 (dd, 1H), 5.27 (dd, 1H), 4.53 (d, 2H), 3.97 (s, 3H), 3.73 (q, 2H), 3.31 (q, 1H), 2.95-2.56 (broad, 3H), 1.77 (m, 1H), 1.65-1.41 (broad, 4H), 1.23 (t, 2H), 0.92 (t, 3H).

$^{13}\text{C-NMR}$ [CDCl_3]: δ = 158.4 ($\text{C}_{\text{ar-O}}$), 153.0 (C=O), 147.7 (C_{arH}), 145.1 (C_{ar}), 144.3 (C_{ar}), 134.9 (C_{ar}), 133.3 (CH=), 132.0 (C_{arH}), 130.2 (C_{ar}), 127.8 (C_{ar}), 122.3 (C_{arH}), 119.4 ($\text{CH}_2=$), 119.3 (C_{arH}), 119.2 (C_{arH}), 102.0 (C_{arH}), 74.8 (CH), 74.2 (CH_2), 59.8 (CH), 58.8 (CH_2), 56.0 ($\text{CH}_3\text{-O}$), 50.1 (CH_2), 37.7 (CH), 27.6 (CH_2), 26.3 (CH), 25.9 (CH_2), 24.4 (CH_2), 12.4 (CH_3).

IR: 2933 cm^{-1} , 2870 cm^{-1} , 1729 cm^{-1} ($\nu\text{C=O}$).

MS [ESI, positive]: 592 [M+Na] $^+$, 570 [M+H] $^+$, 286 [M+2H] $^{2+}$.

4.6. Synthesis of Selector 3

9-(3,5-Dichloro-4-propargyloxyphenylcarbamoyl)dihydroquinine (SO3)

1.85 g of commercially available DHQN (5.7 mmol) were dissolved in 100 mL of toluene. After flushing the apparatus with nitrogen 50 mL of toluene were distilled off under nitrogen atmosphere. After finishing the drying process 1.41 g of purified solid **L2** (5.8 mmol) and 30 μL of DBTDL as a catalyst were added. The reaction mixture

was refluxed for 18 h. The clear dark green solution was then evaporated to dryness and because of several by-products visible on TLC the crude product was purified by flash column chromatography on silica (150 g silica, CH₂Cl₂/MeOH 10:1). The fractions with product were collected, filtered and evaporated under reduced pressure. The pre-purified not fully dry greenish solid was then coated onto 7.50 g of silica and further purified by flash column chromatography on silica (150 g silica, CH₂Cl₂/MeOH 10:1). The fractions with the pure product monitored by TLC were collected, filtered, evaporated and the obtained solid product was dried under reduced pressure.

Yield: 2.10 g (3.7 mmol, 65%) of a slightly greenish solid.

¹H-NMR [CDCl₃]: δ = 8.60 (d, 1H), 7.91 (d, 1H), 7.41 (d, 1H), 7.30 (d, 1H), 7.20 (s, 2H), 7.19 (d, 1H), 6.46 (d, 1H), 4.64 (d, 2H), 3.89 (s, 3H), 3.27 (q, 1H), 3.08-2.89 (broad, 2H), 2.56 (m, 1H), 2.43 (t, 1H), 2.29(d, 1H), 1.83-1.71 (broad, 2H), 1.69-1.59 (broad, 1H), 1.51-1.32 (broad, 3H), 1.32-1.21 (broad, 2H), 0.80 (t, 3H).

¹³C-NMR [CDCl₃]: δ = 158.6 (C_{ar}-O), 152.8 (C=O), 147.7 (C_{ar}H), 146.4 (C_{ar}), 145.2 (C_{ar}), 143.7 (C_{ar}), 135.4 (C_{ar}), 132.1 (C_{ar}H), 130.4 (C_{ar}Cl), 127.6 (C_{ar}), 122.4 (C_{ar}H), 119.2 (C_{ar}H), 101.8 (C_{ar}H), 78.3 (CH≡), 76.6 (C₄), 60.9 (CH₂), 59.3 (CH), 58.5 (CH₂), 56.2 (CH₃-O), 43.0 (CH₂), 37.7 (CH), 28.7 (CH₂), 28.1 (CH₂), 25.6 (CH), 24.7 (CH₂), 12.5 (CH₃).

IR: 3298 cm⁻¹ (ν≡CH), 2930 cm⁻¹, 2868cm⁻¹, 1730 cm⁻¹ (νC=O).

MS [ESI, positive]: 1158 [2M+Na]⁺, 568 [M+H]⁺, 284 [M+2H]²⁺.

4.7. Synthesis of Selector 4

3,5-Dichloro-4-propargyloxyphenylisocyanate (L2)

80 mL of toluene were dried via azeotropic distillation (30 mL of the solvent were removed). After addition of 2.38 g of dry acyl azide **5b** (8.8 mmol), the yellowish solution was refluxed for 3 h to get the isocyanate **L2** via Curtius-rearrangement. Then the solution was cooled to room temperature. An infrared spectrum of the solution confirmed the successful quantitative acyl azide conversion to isocyanate.

IR: 2261 cm⁻¹ (νN=C=O).

9-(3,5-Dichloro-4-propargyloxyphenylcarbamoyl)dihydroquinidine (SO4)

2.10 g of DHQD (6.4 mmol) were suspended in 80 mL of toluene. After flushing the apparatus with nitrogen 40 mL of toluene were distilled off under nitrogen atmosphere. The suspension was cooled below the boiling point of toluene and then the previously prepared solution of **L2** in dry toluene was added under nitrogen. Additional 30 mL of solvent were distilled off before adding 40 μ L of DBTDL as a catalyst. The reaction mixture was then refluxed for 18 h. The initially white suspension became gradually turbid yellowish and a slightly brownish precipitate was formed at the bottom of the flask.

After 18 h the reaction mixture was evaporated to dryness. The crude product was coated onto 15 g of silica and purified by flash column chromatography (200 g silica, CH₂Cl₂/MeOH 10:1). The fractions with pure product monitored by TLC were collected, filtered and evaporated to dryness.

Yield: 2.07 g (3.6 mmol, 56%) of slightly brownish crystals.

¹H-NMR [CDCl₃]: δ = 8.68 (d, 1H), 7.99 (d, 1H), 7.45 (d, 1H), 7.37 (s, 2H), 7.34 (d, 1H), 7.30 (d, 1H), 6.53 (d, 1H), 4.71 (d, 2H), 3.95 (s, 3H), 3.28 (q, 1H), 2.93-2.85 (broad, 1H), 2.82-2.54 (broad, 3H), 2.50 (t, 1H), 1.80-1.72 (broad, 2H), 1.61-1.53 (broad, 2H), 1.50-1.38 (broad, 2H), 1.27-1.21 (broad, 2H), 0.90 (t, 3H).

¹³C-NMR [CDCl₃]: δ = 158.5 (C_{ar}-O), 152.9 (C=O), 147.7 (C_{ar}H), 146.4 (C_{ar}), 145.1 (C_{ar}), 144.2 (C_{ar}), 135.5 (C_{ar}), 132.1 (C_{ar}H), 130.4 (C_{ar}Cl), 127.8 (C_{ar}), 122.3 (C_{ar}H), 119.2 (C_{ar}H), 101.9 (C_{ar}H), 78.2 (CH \equiv), 76.6 (C₄), 74.2 (CH), 60.9 (CH₂), 59.8 (CH), 56.0 (CH₃-O), 51.2 (CH₂), 37.7 (CH), 27.6 (CH₂), 26.3 (CH), 25.9 (CH₂), 24.4 (CH₂), 12.4 (CH₃).

IR: 3296 cm⁻¹ (ν ≡CH), 2932 cm⁻¹, 2870 cm⁻¹, 1728 cm⁻¹ (ν C=O).

MS [ESI, positive]: 568 [M+H]⁺, 284 [M+2H]²⁺.

4.8. Immobilization of SO1 onto MP-Silica = CSP1

2.57 g of mercaptopropyl-modified silica (5 μ m, 120 Å, endcapped with hexamethyl-disilazane, 650 μ mol thiol-groups per gram modified silica, corresponding to 1.67 mmol thiol-groups), 1.76 g of **SO1** (3.09 mmol) and 228 mg of AIBN as a radical starter were suspended in 25 mL of MeOH under nitrogen atmosphere. The suspension was mechanically stirred and heated under reflux. After 18 h the reaction mixture was cooled to room temperature and the modified silica was filtered with a

frit and washed with MeOH and CH₂Cl₂ (each 3x50 mL). After drying under vacuum at 60°C SO loading was determined by elemental analysis (EA).

Yield: 2.56 g.

EA: C: 10.93 w-%; H: 1.75 w-%; N: 0.749 w-%; S: 1.94 w-%; Cl: 0.960 w-%.

SO loading calculated according to the nitrogen content: 179 µmol/g.

4.9. Immobilization of SO₂ onto MP-Silica = CSP2

2.49 g of **MP-Silica** (5 µm, 120 Å, endcapped with hexamethyl-disilazane, 660 µmol thiol-groups per gram modified silica, corresponding to 1.64 mmol thiol-groups), 1.76 g **SO₂** (3.10 mmol) and 212 mg of AIBN as a radical starter were suspended in 30 mL of MeOH under nitrogen atmosphere. The suspension was mechanically stirred and heated under reflux. After 18 h the reaction mixture was cooled to room temperature and the silica was filtered with a frit and washed with MeOH and CH₂Cl₂ (each 3x50 mL). After drying under vacuum at 60°C SO loading was determined by elemental analysis.

Yield: 2.64 g.

EA: C: 9.41 w-%; H: 1.64 w-%; N: 0.59 w-%; S: 1.92 w-%; Cl: 0.91 w-%.

SO loading calculated according to the nitrogen content: 144 µmol/g.

4.10. Synthesis of AzP-Silica

Chloropropyl-modified silica (CP-Silica)

15.78 g of silica (Daisogel for HPLC; Grade SP-120-5P, 5 µm, 120 Å) were suspended in 200 mL toluene and dried via azeotropic distillation. During the distillation 20 mg of p-toluenesulfonic acid were added to the suspension and also dried together with toluene and silica. After distilling off 100 mL of the solvent, the descending condenser was replaced by a dry reflux condenser and 4.6 mL of 3-chloropropyltrimethoxysilane (25 mmol) were added to the suspension. The reaction mixture was mechanically stirred and heated under reflux for 18 h. The suspension was then cooled to room temperature, filtered with a frit, washed with toluene and methanol (each 2x100 mL) and resuspended in 100 mL toluene again. This suspension was mechanically stirred for 0.5 h and heated under reflux.

Afterwards the suspension was filtered and washed the same way as before. **CP-Silica** was then dried under vacuum at 60°C and chloropropyl-loading was determined by elemental analysis.

Yield: 17.19 g.

EA: C: 3.61 w-%; H: 1.01 w-%; N: < 0.03 w-%; S: < 0.01 w-%; Cl: 2.63 w-%.

Chloropropyl-loading calculated according to the chlorine content: 742 µmol/g.

Azidopropyl-modified silica (**AzP-Silica**)

17.19 g of **CP-Silica** were suspended in 110 mL 0.5 M NaN₃ in warm DMSO (55 mmol) and 60 mg of tetrabutylammonium iodide as a catalyst were added. This reaction mixture was then mechanically stirred for 72 h at 80°C. **AzP-Silica** was then filtered with a frit, washed with 500 mL H₂O and 250 mL MeOH and dried under vacuum. Azide-loading was determined by elemental analysis.

Yield: 16.07 g.

EA: C: 3.64 w-%; H: 0.92 w-%; N: 2.64 w-%; S: < 0.01 w-%; Cl: 0.18 w-%.

Azidopropyl-loading calculated according to the nitrogen content: 629 µmol/g (85% conversion from chloropropyl to azidopropyl).

4.11. Immobilization of SO₃ onto AzP-Silica = CSP3

3.00 g of **AzP-Silica** (corresponding to 1.89 mmol -N₃) and 1.78 g **SO₃** (3.13 mmol) were suspended in 60 mL of ACN in a glass bottle. 1.06 mL (6.25 mmol) of *N,N*-diisopropylethylamine were added and the suspension was sealed with a septum and degassed by flushing with N₂ through a syringe needle for 10 min. 25 mg of CuI (0.13 mmol, 6.9 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker at room temperature. After 48 h additional 22 mg of catalyst (0.12 mmol, 6.3 mol%) were added under nitrogen flushing, the glass bottle was closed and the reaction continued under given conditions. After 72 h the other reaction mixture was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP3** was then dried under vacuum at 60°C for 72 h. SO loading was determined by elemental analysis.

Yield: 4.07 g.

EA: C: 19.20 w-%; H: 2.16 w-%; N: 4.24 w-%; S: < 0.02 w-%; Cl: 3.38 w-%.

SO loading calculated according to the chlorine content: 477 $\mu\text{mol/g}$ (76% conversion of azido-groups).

4.12. Immobilization of SO₄ onto AzP-Silica = CSP4

3.00 g of **AzP-Silica** (corresponding to 1.89 mmol -N₃) and 1.73 g of **SO₄** (3.04 mmol) were suspended in 60 mL of ACN in a glass bottle. 1.06 mL of DIPEA (6.25 mmol) were added and the suspension was degassed for 10 min as described above. 25 mg of CuI (0.13 mmol, 6.9 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. After 48 h additional 21 mg of catalyst (0.11 mmol, 5.8 mol%) were added under nitrogen flushing and the reaction continued under given conditions. After additional 24 h the other reaction mixture was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP4** was then dried under vacuum at 60°C for 72 h. SO loading was determined by elemental analysis.

Yield: 4.13 g.

EA: C: 19.04 w-%; H: 2.19 w-%; N: 4.18 w-%; S: < 0.02 w-%; Cl: 3.48 w-%.

SO loading calculated according to the chlorine content: 490 $\mu\text{mol/g}$ (78% conversion of azido-groups).

4.13. Immobilization of SO₃ onto AzP-Silica = CSP5

3.50 g of **AzP-Silica** (corresponds to 2.20 mmol -N₃) and 458 mg of **SO₃** (0.81 mmol) were suspended in 60 mL of ACN in a glass bottle. 1.24 mL of DIPEA (7.31 mmol) were added and the suspension was degassed by flushing with N₂ for 10 min as described above. 28 mg of CuI (0.15 mmol, 7.4 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. After 48 h additional 25 mg of catalyst (0.13 mmol, 6.0 mol%) were added under nitrogen flushing and the reaction continued under given conditions. After

additional 24 h the greenish reaction suspension was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP5** was then dried under vacuum at 60°C for three days. SO loading was determined by elemental analysis.

Yield: 3.90 g.

EA: C: 10.04 w-%; H: 1.41 w-%; N: 3.42 w-%; S: < 0.02 w-%; Cl: 1.52 w-%.

SO loading calculated according to the chlorine content: 214 µmol/g (93% of **SO3** immobilized).

4.14. Immobilization of **SO4** onto **AzP-Silica** = **CSP6**

2.40 g of **AzP-Silica** (corresponding to 1.51 mmol -N₃) and 341 mg of **SO4** (250 µmol/g silica) were suspended in 50 mL of ACN in a glass bottle. 886 µL of DIPEA were added (5.21 mmol) and the suspension was degassed by flushing with N₂ for 10 min. 36 mg of CuI (189 µmol, 12.5 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. The other suspension was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP6** was then dried under vacuum at 60°C for 24 h. SO loading was determined by elemental analysis.

Yield: 2.68 g.

EA: C: 9.90 w-%; H: 1.38 w-%; N: 3.11 w-%; S: < 0.02 w-%; Cl: 1.83 w-%.

SO loading calculated according to the chlorine content: 232 µmol/g (93% of **SO4** immobilized).

4.15. Preparation of **CSP7**

1.23 g of **CSP4** (490 µmol **SO4** per gram silica) were combined with 1.28 g of **AzP-Silica** (azidopropyl-loading of 629 µmol/g) and suspended in 250 mL of MeOH to result in a calculated final selector-concentration of 240 µmol/g. This suspension was mechanically stirred at room temperature for 4 h. Afterwards the homogeneously mixed silica material was filtered and washed with 50 mL of MeOH. **CSP7** was dried under vacuum at 60°C for 24 h. SO loading was determined by elemental analysis.

Yield: 2.50 g.

EA: C: 11.14 w-%; H: 1.54 w-%; N: 3.34 w-%; S: < 0.02 w-%; Cl: 1.69 w-%.

SO loading calculated according to the chlorine content: 238 $\mu\text{mol/g}$ (99% of the expected value).

4.16. Immobilization of SO₄ onto AzP-Silica = CSP8

2.50 g of **AzP-Silica** (corresponding to 1.57 mmol -N₃) and 512 mg of **SO₄** (0.90 mmol) were suspended in 60 mL of ACN in a glass bottle. 1.0 mL of DIPEA was added (5.88 mmol) and the suspension was degassed by flushing with N₂ for 10 min. 50 mg of CuI (263 μmol , 17 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. The yellow suspension was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP8** was then dried under vacuum at 60°C for 24 h. SO loading was determined by elemental analysis.

Yield: 2.79 g.

EA: C: 12.96 w-%; H: 1.65 w-%; N: 3.28 w-%; S: < 0.02 w-%; Cl: 2.23 w-%.

SO loading calculated according to the chlorine content: 314 $\mu\text{mol/g}$ (87% of **SO₄** immobilized).

4.17. Immobilization of SO₄ onto AzP-Silica = CSP9

10.0 g of **AzP-Silica** (corresponding to 6.29 mmol -N₃) and 853 mg of **SO₄** (1.50 mmol) were suspended in 200 mL of ACN in a glass bottle. 10 mL of DIPEA were added (58.8 mmol) and the suspension was degassed by flushing with N₂ for 15 min. 200 mg of CuI (1.05 mmol, app. 17 mol% according to -N₃) as a catalyst were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. The yellow suspension was filtered with a frit and washed with ACN, MeOH, 2x2 w-% EDTA in H₂O, MeOH/H₂O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 300 mL). **CSP9** was then dried under vacuum at 60°C for 24 h. SO loading was determined by elemental analysis.

Yield: 10.46 g.

EA: C: 7.75 w-%; H: 1.24 w-%; N: 2.82 w-%; S: < 0.02 w-%; Cl: 1.24 w-%.

SO loading calculated according to the chlorine content: 150 $\mu\text{mol/g}$ (**SO4** quantitatively immobilized).

4.18. Endcapping of **CSP9** resulting in **CSP10**

2.5 g of **CSP9** (**SO4** loading of 150 $\mu\text{mol/g}$) were suspended in 60 mL of ACN in a glass bottle. 1.0 mL of DIPEA was added (5.88 mmol) and the suspension was degassed by flushing with N_2 for 10 min. 50 mg of CuI (0.26 mmol, app. 22 mol% according to free $-\text{N}_3$) as a catalyst and 100 μL of propargyl alcohol (1.73 mmol) were added under nitrogen flushing and the glass bottle was closed and sealed with Parafilm[®]. The sealed glass bottle was shaken for 72 h on an overhead shaker. The yellow suspension was filtered with a frit and washed with ACN, MeOH, 2 w-% EDTA in H_2O , MeOH/ H_2O 1:1 v/v, 10 v-% AcOH in MeOH and pure MeOH (each 150 mL). **CSP10** was then dried under vacuum at 60°C for 24 h. SO loading was determined by elemental analysis.

Yield: 2.49 g of a slightly yellowish modified silica.

EA: C: 8.98 w-%; H: 1.33 w-%; N: 2.72 w-%; S: < 0.02 w-%; Cl: 1.16 w-%.

SO loading calculated according to the chlorine content: 138 $\mu\text{mol/g}$ (92% of **CSP9**, 8% of **SO4** have been splitted off during endcapping and the work-up process).

4.19. Column-packing

Column-packing was carried out in the same way for every single CSP and the AzP-Silica-Column using standard slurry-method. The modified silica was sieved through a 40 μm sieve and 2.30 g of it were suspended in 20 mL of iPrOH and 1.0 mL AcOH.

The suspension was homogenized in an ultrasonic bath for 20 min and the silica material was packed *in house* under high pressure (app. 650 bar) into a 150x4 mm ID Bischoff stainless steel HPLC column followed by rinsing with methanol (**columns 1 to 10, 13, 14 and 16**).

When packing 75x4 mm ID columns only 1.80 g of CSP were used for packing (**columns 11, 12 and 15**). Before using the packed columns they were rinsed with 100 mL 1.0 w-% aqueous EDTA solution (except **columns 1, 2 and 13 to 16**), 50 mL bidistilled H₂O and 100 mL of MeOH.

II. List of Abbreviations

| | | | |
|------------|---|----------------|---|
| /// | no value, no data | MeOH | methanol |

IV. Conclusion and Outlook

The focus of the present master thesis was the synthesis and evaluation of novel arylcarbamoylated cinchona-based weak anion exchange type chiral stationary phases for liquid chromatography.

Commercially available dihydroquinine and corresponding pseudoenantiomeric dihydroquinidine as the building blocks were carbamoylated with two different linkers. In total four different selectors were successfully synthesized, wherein each two of them are pseudoenantiomers. Due to the protonation of the quinuclidine ring of the building blocks under weakly acidic mobile phase conditions anion exchange takes place.

On the basis of two differently substituted linkers (one allylated and one propargylated) it was possible to use two different immobilization strategies – radical mediated thiol-ene addition or Cu(I) and base catalyzed Huisgen alkyne-azide click chemistry. The radical addition onto mercaptopropyl-modified silica yielded low immobilization efficiencies; on the other hand, it was possible to control the amount of immobilized selector via alkyne-azide click chemistry, which yielded saturated selector densities in case the selector was offered in excess. Altogether ten CSPs with different selector loadings were synthesized through immobilization of the four selectors.

All CSPs were then evaluated in terms of their capability for enantioseparation with a set of 67 analytes; most of them were chiral acidic compounds. For comparative purposes two commercially available CSPs (QN-AX and QD-AX) were used as well. As a trend it was observed that the immobilization via radical thiol-ene addition results in higher resolution values (taking into account that the selector densities are equal), but this behavior could also be caused by packing phenomena. Free azido groups on modified silica show no contribution to retention. Endcapping of the free azido groups results in higher selectivity and lower resolution. A 1:1 physical mixture prepared from a high loaded CSP and pure azidopropyl-modified silica behaves similarly to a half-length column containing the high loaded material. The elution order changes from DHQN to DHQD type CSPs, whereas DHQD type CSPs exhibit higher selectivity and resolution. The higher the selector loading, the higher the retention. The maximum resolution and selectivity were observed at a selector density of app. 310 $\mu\text{mol/g}$.

All CSPs are well suitable for the separation of *N*-protected aminophosphonates, which is an advantage in comparison to the commercially available QN-AX and QD-AX anion exchangers.

A loading study confirmed an ion exchange mechanism for the retention of acidic analytes under polar organic mode mobile phase conditions. The stoichiometric displacement model was proved to be valid as well.

In summary the synthesis of novel weak anion exchange type CSPs based on carbamoylated cinchona alkaloids was carried out successfully. New findings were achieved employing different immobilization strategies and selector densities. By the usage of the present synthesis protocols and immobilization strategies in combination with a derivatization of the substituted linker it is possible to perform further investigations in the field of enantioseparation in the future.

V. Zusammenfassung

Der Schwerpunkt der vorliegenden Masterarbeit war die Synthese und Evaluierung neuartiger Chinin-basierter chiraler Anionenaustauschermaterialien für die Trennung chiraler organischer Säuren mittels Hochleistungs-Flüssigkeitschromatographie.

Kommerziell erhältliches Dihydrochinin und das entsprechende pseudoenantiomere Dihydrochinidin wurden als chirale Grundbausteine mit zwei verschiedenen Isocyanaten carbamoyliert. Insgesamt konnten vier verschiedene Selektoren erfolgreich synthetisiert werden, wobei jeweils zwei davon als pseudoenantiomere Paare angesehen werden können. Durch Protonierung des Chinuclidinrings der Selektoren unter leicht sauren Bedingungen ist in weiterer Folge Anionenaustausch möglich.

Aufgrund von zwei unterschiedlich substituierten Isocyanaten als Linker (allyliert und propargyliert) war es möglich, zwei verschiedene Strategien für die Immobilisierung der Selektoren zu verwenden - radikale Thiol-En Addition oder Cu(I) und basenkatalysierte Huisgen Alkin-Azid Klick-Chemie. Die radikalische Immobilisierung auf Mercaptopropyl-modifiziertem Kieselgel ergab einerseits eine niedrige Immobilisierungseffizienz, andererseits war es möglich, die Menge an immobilisiertem Selektor über Alkin-Azid Klick-Chemie zu steuern. Zusammenfassend konnten zehn CSP mit unterschiedlicher Selektorbeladung synthetisiert werden.

Alle CSP wurden bezüglich ihrer Fähigkeit zur Trennung von Enantiomeren mit einem Set von 67 Analyten untersucht, wobei die meisten davon chirale saure Verbindungen waren. Zu Vergleichszwecken wurden zwei kommerziell erhältliche CSP (QN-AX und QD-AX) verwendet.

Als Trend wurde beobachtet, dass die Immobilisierung über radikalische Thiol-En-Addition bei gleicher Selektordichte höhere Auflösungen ergibt, was allerdings auch auf Packungsphänomene zurückzuführen sein könnte. Freie Azidogruppen auf modifiziertem Kieselgel liefern keinen Beitrag zur Retention der Analyten. Endcapping der freien Azidogruppen führt einerseits zu höherer Selektivität, andererseits zu geringerer Auflösung. Eine 1:1 physikalische Mischung hergestellt aus einer hoch belegten CSP und Azidopropyl-modifiziertem Kieselgel verhält sich ähnlich wie eine Säule, welche mit hoch belegtem Material gepackt wurde und nur die halbe Länge aufweist.

Eine Umkehr der Elutionsreihenfolge von DHQN zu DHQD Typ CSP konnte bei allen Analyten beobachtet werden, wobei die DHQD Typ CSP generell eine höhere Selektivität und Auflösung zeigten. Je höher die Selektordichte, desto größer war die Retention, jedoch begleitet von einer Abnahme der Selektivität. Das Maximum an Auflösung und Selektivität wurde bei einer Selektordichte von zirka 310 $\mu\text{mol/g}$ beobachtet.

Die synthetisierten chiralen stationären Phasen waren sehr gut für die Trennung von *N*-geschützten Aminophosphonaten geeignet, was ein Vorteil im Vergleich zu den im Handel erhältlichen QN-AX und QD-AX Anionenaustauschermaterialien ist.

Eine Beladungsstudie bestätigte einen Ionenaustausch-Mechanismus für die Retention von sauren Analyten. Die Gültigkeit des stöchiometrischen Verdrängungs-Modells konnte ebenfalls erwiesen werden.

Zusammenfassend konnte die Synthese neuer Anionenaustauscherphasen für Hochleistungsflüssigkeitschromatographie auf der Basis von arylcarbamoyleierten Chinin-Derivaten erfolgreich durchgeführt werden. Neue Erkenntnisse konnten durch den Einsatz unterschiedlicher Immobilisierungs-Strategien und Selektordichten auf der Kieselgeloberfläche gewonnen werden. Durch diese Erkenntnisse und die Verwendung der vorliegenden Syntheseprotokolle und Immobilisierungsstrategien in Kombination mit einer Derivatisierung des substituierten Linkers ist es möglich, weitere Untersuchungen auf dem Gebiet der Enantiomerentrennung durchzuführen.

VI. Curriculum Vitae

Name: Hubert Hettegger
Geburtsdatum: 29.09.1988 (Schwarzach im Pongau)
Staatsbürgerschaft: Österreich
Adresse: Höritzergasse 4/7
1140 Wien

Schulbildung:

| | |
|-----------|---|
| 1994-1998 | Volksschule St. Veit im Pongau |
| 1998-2006 | Privatgymnasium der Herz Jesu Missionare in Salzburg/Liefering |
| 2006 | Matura |

Studium:

| | |
|---------------|--|
| 2006 bis 2010 | Bachelorstudium Chemie an der Universität Wien |
| 2010 bis 2012 | Masterstudium Chemie an der Universität Wien |
| 2011 bis 2012 | Masterarbeit |
