EMBEDDED EIGENVALUES FOR WATER-WAVES IN A THREE
DIMENSIONAL CHANNEL WITH A THIN SCREEN

VALERIA CHIADÓ PIAT, SERGEY A. NAZAROV, AND JARI TASKINEN

Abstract. We construct asymptotic expansions as $\varepsilon \to +0$ for an eigenvalue embedded into the continuous spectrum of water-wave problem in a cylindrical three dimensional channel with a thin screen of thickness $O(\varepsilon)$. The screen may be either submerged or surface-piercing, and its wetted part has a sharp edge. The channel and the screen are mirror symmetric so that imposing the Dirichlet condition in the middle plane creates an artificial positive cut-off-value $\Lambda_\dagger$ of the modified spectrum. Depending on a certain integral characteristic $I$ of the screen profiles, we find two types of asymptotics of eigenvalues, $\lambda_\varepsilon = \Lambda_\dagger - O(\varepsilon^2)$ and $\lambda_\varepsilon = \Lambda_\dagger - O(\varepsilon^4)$ in the cases $I > 0$ and $I = 0$, respectively. We prove that in the case $I < 0$ there are no embedded eigenvalues in the interval $[0, \Lambda_\dagger]$, while this interval contains exactly one eigenvalue, if $I \geq 0$. For the justification of these result, the main tools are a reduction to an abstract spectral equation and the use of the max-min-principle.

1. Introduction

1.1. Formulation of the problem. Spectral elliptic problems modelling physical phenomena in unbounded domains nearly always have continuous spectra, which allow wave processes in the related frequency ranges in the physical systems under consideration. The spectrum may also contain eigenvalues embedded in the continuous spectrum. Eigenfunctions corresponding to these eigenvalues have finite energy and usually decay rapidly at infinity, which means that they are localized in a bounded region and for this reason called "trapped modes". Such trapped modes prevent wave propagation and promote the accumulation of energy, and thus are related with interesting physical phenomena. They may be unwanted, as they may cause damage to mechanical structures, or wanted, for example for the design of wave filters and dampers.

The physical system considered in this paper is the linearised water-wave model. We investigate the interaction of water-waves with a thin screen, which is submerged or surface piercing in a cylindrical three dimensional channel. The channel is infinite and invariant along the longitudinal $x_1$-direction, moreover, it and the screen are assumed to be mirror symmetric with respect to the transversal $x_2$-direction. The wave motion is supposed to take place in an incompressible and inviscid fluid. Our aim is to discuss the existence and uniqueness of an eigenvalue embedded in the continuous spectrum. The main results, Theorems 1.1 and 3.1, state that such an eigenvalue exists depending on the behaviour of a certain integral characteristic $I(h)$.

Key words and phrases. linear water wave system, cylindrical channel, Steklov condition, asymptotic analysis, artificial Dirichlet condition, continuous spectrum, embedded eigenvalue.

to be defined later. Indeed, we shall show that, in the case $I(h) < 0$, no eigenvalues exist in the interval $(0, \Lambda_1)$, where $\Lambda_1$ is a positive, artificial cut-off point, and that for $I(h) \geq 0$ an eigenvalue does exist in $(0, \Lambda_1)$. However, in the cases $I(h) > 0$ and $I(h) = 0$ the eigenvalues have different asymptotic behaviour. For a sufficiently thin screen an eigenvalue is shown to be unique in $(0, \Lambda_1)$ so that the inequality $I(h) \geq 0$ becomes a criterion for a trapped mode. The edge of the screen is assumed to be sharp, which simplifies our justification scheme but on the other hand requires an elaborate analysis of singularities of solutions on the edge, see Section 3.3.

The special feature of the linear-water wave equation is the appearance of spectral parameter in the Steklov boundary condition of the free water surface. This makes a direct application of the classical Sobolev-space methods difficult, see for example the review paper [14] and the monograph [13], especially for an approach based on the application of the Dirichlet-to-Neumann-(or Steklov-Poincaré-)operator. We follow here the modified techniques used for example in [18, 25] which are based, among other things, on an unconventional definition of the problem operator with mixed types of inner products containing both volume and surface integrals; see (4.13). This method has been used to proving or disproving the existence of an eigenvalue in some interval, but here we use it, together with a new asymptotic approach, for obtaining precise information on the position of the lowest embedded eigenvalue. (We expect the method will eventually make it possible to find a point with complex resonance, if the symmetry assumed in this paper is broken. However, this study is postponed to a planned forthcoming paper, since it will require new techniques.)

Let us proceed by describing the water domain in detail. We define a three dimensional channel (Fig. 1.1.a) by

\begin{equation}
\Pi = \{ x = (x_1, x_2, x_3) = (x_1, x') : x_1 \in \mathbb{R}, x' \in \varpi \} = \mathbb{R} \times \varpi,
\end{equation}

where the cross-section $\varpi \subset \mathbb{R}^2$ is a bounded domain, the boundary $\partial \varpi$ of which consists of the line segment

\begin{equation}
\gamma = \{ x' = (x_2, x_3) : z = x_3 = 0, |x_2| < l \}, \quad l > 0,
\end{equation}

and of a smooth arc $\varsigma \subset \mathbb{R}^-_2 = \{(x_2, x_3) : x_3 < 0 \}$ connecting the points $P^\pm = (\pm l, 0)$.

The thin screen $\Theta^\varepsilon$ depending on the small parameter $\varepsilon > 0$ is described as follows. Let $\theta \subset \mathbb{R}^2$ an open subset of $\varpi$, such that $P^\pm \notin \bar{\theta} = \theta \cup \partial \theta$. Assuming that two, not identically zero profile functions $h_\pm \in C^2(\theta)$ are given such that $h = h_+ + h_- \geq 0$, we define the thin screen, flat screen and the profile boundary, respectively, by

\begin{align}
\Theta^\varepsilon &= \{ x : x' \in \varrho, -\varepsilon h_-(x') \leq x_1 \leq \varepsilon h_+(x') \} , \\
\Theta^0 &= \{ x : x' \in \varrho, x_1 = 0 \}, \\
\Theta^\varepsilon_\pm &= \{ x : x' \in \theta, x_1 = \pm \varepsilon h_\pm(x') \} .
\end{align}

By rescaling we reduce the characteristic size of the cross section $\varpi$ to one and, therefore, make the Cartesian coordinates $x$ and all geometric parameters dimensionless. For the sake of simplicity we assume that the curve $\psi = \partial \theta \cap \varpi$ is smooth and that $\psi$ and $\varsigma$ both intersect $\gamma$ at right angle $\alpha = \pi/2$. Note in particular that in this case the boundary is certainly non-cuspidal; cuspidal boundaries, possibly causing non-empty continuous spectra and thus wave processes even in finite volume domains, were studied in [24].
We denote by $\Omega^\varepsilon = \Pi \setminus \Theta^\varepsilon$, $\varepsilon \geq 0$, the channel (1.1) with the thin or flat vertical screen (1.3), Fig. 1.2.a, and consider the propagation of water-waves along the horizontal free surface

\begin{equation}
\Gamma^\varepsilon = \Gamma \setminus \Theta^\varepsilon,
\end{equation}

where $\Gamma = \mathbb{R} \times \gamma$ is the intact channel surface. Notice that $\Gamma$ can be pierced by the screen, but in the case $\partial \theta \cap \gamma = \emptyset$ the obstacle $\Theta^\varepsilon$ is submerged, and, therefore $\Gamma^\varepsilon = \Gamma$. The bottom and walls $\Sigma = \mathbb{R} \times \varsigma$ of the channel $\Pi$ can be touched by the obstacle, too, and we denote

\begin{equation}
\Sigma^\varepsilon = \Sigma \setminus \Theta^\varepsilon.
\end{equation}

Our analysis is based on the usual assumptions of the linear water-wave theory: the motion is irrotational and of small amplitude. These assumptions and the incompressibility of the fluid allow us to define a three-dimensional velocity potential, $W^\varepsilon = W^\varepsilon(x,t)$, which satisfies the Laplace equation in the water domain. On the free surface we impose kinematic and dynamic boundary conditions which, ignoring surface tension, translate to continuity of the normal velocity and the pressure. We take the constant ambient pressure above the free surface to be zero. For small-amplitude waves, it makes sense to consider linearised equations of motion and, assuming that the motion is time harmonic along the cylinder in the $x_1$-direction, we thus seek for a velocity potential of the form $W^\varepsilon(x,t) = \text{Re} \left( u^\varepsilon(x) e^{i(kx_1 - \omega^\varepsilon t)} \right)$, where both the radian frequency $\omega^\varepsilon$ and the wave number $k$ are taken real, say $k > 0$, so that the solution stays bounded for all $x$ and $t$. Due to small surface elevations, the boundary condition on the free surface is written at a flat horizontal surface. On substituting $W^\varepsilon$ into the linearised equations of motion, we obtain the following equations. For any $\varepsilon > 0$, the velocity potential $u^\varepsilon$ satisfies the Laplace equation

\begin{equation}
-\Delta u^\varepsilon(x) = 0, \quad x \in \Omega^\varepsilon,
\end{equation}

the Neumann (no-flow) boundary condition on the wetted surfaces (1.7) and (1.5),

\begin{equation}
\partial_n u^\varepsilon(x) = 0, \quad x \in \Sigma^\varepsilon \cup \theta^\varepsilon_+ \cup \theta^\varepsilon_-,
\end{equation}

and the kinematic condition on the linearised water surface (1.6)

\begin{equation}
\partial_z u^\varepsilon(x) = \lambda^\varepsilon u^\varepsilon(x), \quad x \in \Gamma^\varepsilon.
\end{equation}
We denote the gradient and Laplacian with respect to the variable $x$ by $\nabla$ and $\Delta$, while $\partial_z$ and $\partial_\nu$ stand for the partial derivative with respect to $z = x_3$ and the outer unit normal, respectively. Moreover, $\lambda^\varepsilon = g^{-1}(\omega^\varepsilon)^2$ is a spectral parameter, where $g > 0$ is the acceleration of gravity.

Since the boundary $\partial \Omega^\varepsilon$ has an edge-type irregularity, we impose the traditional Meixner condition [16], which implies the square integrability of the velocity vector $\nabla u^\varepsilon$. This condition is assumed throughout the paper, see Section 3.3.

We make the following assumptions on symmetry and shape of the screen, the role of which will be discussed in Section 1.3.

1°. Both $\varpi$ and $\theta$ are symmetric with respect to the axis $\{x' : x_2 = 0\}$.

2°. Both profile functions $h^\pm$ in (1.3), (1.5) are even in $x_2$.

3°. We have $h^\pm(x') = 0$ for $x' \in \psi = \partial \theta \setminus \gamma$.

1.2. Main results and plan of the paper. It is known that the spectrum of the problem (1.8)–(1.10) is continuous and coincides with the intact closed positive semi-axis $\mathbb{R}^+ = [0, +\infty) \subset \mathbb{C}$, see [13]. However, it may contain embedded eigenvalues associated with exponentially decaying eigenfunctions. The main purpose of our paper is to derive and justify an asymptotic formula for such eigenvalues as well as to prove a uniqueness result. To this end we shall use in Section 1.3 the symmetry assumptions 1°–3° to introduce a problem (1.15)–(1.18) with an artificial Dirichlet condition on the symmetry plane. The continuous spectrum of this problem is known to be the interval $[\Lambda^\dagger, +\infty)$, where the threshold $\Lambda^\dagger$ is positive. In Sections 2 and 3 we construct formal asymptotics for an eigenvalue

$$(1.11) \quad \lambda^\varepsilon = \Lambda^\dagger - \widehat{\lambda}^\varepsilon, \quad \widehat{\lambda}^\varepsilon \to +0 \text{ as } \varepsilon \to +0.$$ 

of the problem (1.15)–(1.18); $\lambda^\varepsilon$ is also an eigenvalue of the problem (1.8)–(1.10).

Two different cases with $\widehat{\lambda}^\varepsilon \approx \lambda_0^2\varepsilon^2$, (2.1), and $\widehat{\lambda}^\varepsilon \approx \lambda_1^4\varepsilon^4$, (3.2), will be found. In Section 2 we introduce an integral characteristic (2.28), denoted by $I(h)$, such that for $I(h) > 0$ the correction term $\widehat{\lambda}^\varepsilon \approx \lambda_0^2\varepsilon^2$ is positive, but for $I(h) < 0$ it is not. Accordingly, we formulate the first main result of our paper as follows

**Theorem 1.1.** Assume that the conditions 1°–3° hold true. Then, there exists $\varepsilon_1 = \varepsilon_1(\theta, h^\pm) > 0$ such that...
1) if $I(h) < 0$, the problem (1.8)–(1.10) has no eigenvalue in the segment $[0, \Lambda_1]$, when $\varepsilon \in (0, \varepsilon_1]$. 
2) if $I(h) > 0$, the problem (1.8)–(1.10) has for every $\varepsilon \in (0, \varepsilon_1]$ a unique eigenvalue (1.11) inside the segment $[0, \Lambda_1]$. The coefficient $\lambda_0 > 0$ is given by (2.31), (2.28) and the asymptotic remainder $\tilde{\lambda}^c = \lambda^c - (\Lambda_1 - \lambda_0 \varepsilon_0^2) = \lambda_0 \varepsilon_0^2 - \tilde{\lambda}^c$ satisfies the estimate

$$|\tilde{\lambda}^c| \leq c_1 \varepsilon^{5/2},$$

where $c_1$ is independent of the small parameter $\varepsilon$.

The most complicated case $I(h) = 0$ will be examined in Section 3, where we borrow an elegant idea [6] of the Dirichlet boundary condition on the midplane of the waveguide $\Pi_\varepsilon$, for which we need the symmetry assumptions $1^\circ$. These requirements allow us to restrict the problem (1.8)–(1.10) to the half-channel $\Omega_\varepsilon$,

$$\Omega_\varepsilon = \{ x \in \Omega^c : x_2 > 0 \},$$

and to impose the artificial Dirichlet condition on the middle plane

$$\Upsilon^c = \{ x \in \Omega^c : x_2 = 0 \} = \Upsilon \setminus \Theta^c,$$

$$\Upsilon = \nu \times \mathbb{R}, \quad \nu = \{ x' \in \varpi : x_2 = 0 \}.$$

All objects restricted to the domain (1.13) are supplied with the subscript $r$ so that the new problem reads as

$$-\Delta u^c(x) = 0, \quad x \in \Omega_\varepsilon^c,$$

$$\partial_{\nu} u^c(x) = 0, \quad x \in \Sigma_r \cup \theta^c_{+r} \cup \theta^c_{-r},$$

$$\partial_{\zeta} u^c(x) = \lambda^c u^c(x), \quad x \in \Gamma_r,$$

$$u^c(x) = 0, \quad x \in \Upsilon^c.$$
As motivation for studying this problem with the artificial boundary condition we mention that the continuous spectrum of the problem (1.15)–(1.18) coincides with the ray \([\Lambda_t, +\infty)\), where \(\Lambda_t > 0\) (see below). Hence, there may still exist discrete spectrum of (1.15)–(1.18) contained in the interval \((0, \Lambda_t)\), and if this happens, one can make an odd, smooth and harmonic extension of a corresponding eigenfunction \(u^k \in H^1(\Omega^k_r; \mathcal{Y}^k)\) of (1.15)–(1.18), which thus becomes an eigenfunction of the original problem (1.8)–(1.10). This gives us a way to study eigenvalues embedded into the interval \((0, \Lambda_t)\) of the continuous spectrum. Notice that \(\Lambda_t\) is nothing but the first eigenvalue of the model problem on the half-plane \(\mathcal{W}\): \[\Delta'U(x') = 0, \quad x' \in \mathcal{W},\]
\[\partial_{n}U(x') = 0, \quad x' \in \mathcal{S},\]
\[\partial_{z}U(x') = \Lambda U(x'), \quad x' \in \Gamma,\]
\[U(x') = 0, \quad x' \in \mathcal{Y}.\]

Here, \(\Delta'\) is the Laplacian in the coordinates \(x'\). Due to the Dirichlet condition (1.22), the first eigenvalue \(\Lambda = \Lambda_t\) is positive and can be computed from the max-min-principle \[\Lambda_t = \inf_{V} \frac{\|\nabla'V; L^2(\mathcal{W})\|^2}{\|V; L^2(\Gamma)\|^2},\]
where \(\| \cdot ; L^2(D)\|\) denotes the standard norm of the Lebesgue \(L^2\)-space on a domain \(D\), the infimum is taken over all \(V \in H^1_0(\mathcal{W}; \mathcal{V}) \setminus H^1_0(\mathcal{W}; \Gamma)\) and \(H^1_0(\mathcal{W}, \mathcal{Y})\) is the Sobolev space of functions vanishing in the subdomain \(\mathcal{W} \subset \mathcal{W}\). According to the strong maximum principle the corresponding eigenfunction \(U_t\) can be chosen positive in \(\mathcal{W}\) and subject to the normalization condition \[\int_0^t |U_t(x_2, 0)|^2 dx_2 = 1.\]

Since the cut-off value (1.23) is positive, the problem (1.15)–(1.18) may still have non-empty discrete spectrum in the interval \((0, \Lambda_t)\). Moreover, the odd extension with respect to \(x_2\) of an eigenfunction \(u^k \in H^1(\Omega^k_r; \mathcal{Y}^k)\) of (1.15)–(1.18) is smooth and harmonic, and therefore it becomes an eigenfunction of the original problem (1.8)–(1.10). In this way, eigenvalues embedded into the interval \((0, \Lambda_t)\) can be examined using operator theory.

\section{Remark 1.2.} It was observed in [20], in connection with a different spectral problem, that the existence of the eigenvalue (1.11) for (1.8)–(1.10) implies that the limit problem corresponding to \(\varepsilon = 0\):
\[\Delta u^0(x) = 0, \quad x \in \Omega^0_r = \Pi_r \setminus \Theta^0_r,\]
\[\partial_{n}u^0(x) = 0, \quad x \in \Sigma_r \cup \theta^0_r \cup \theta^0_{-r}\]
\[\partial_{z}u^0(x) = \Lambda u^0(x), \quad x \in \Gamma,\]
\[u^0(x) = 0, \quad x \in \mathcal{Y},\]
\[\text{has a solution, which is stabilizing at infinity (i.e. asymptotically equal to a function depending on } x' \text{ only). In our case this stabilizing at infinity-solution can be readily found: it is}\]
\[u^{(0)}(x) = U_t(x'),\]
where $U_\dagger$ is the eigenfunction of (1.19)–(1.22) associated with the eigenvalue $\Lambda_\dagger$. Indeed, on the surfaces $\theta_0^\pm = \{x : x' \in \theta, x_1 = 0\}$ of the flat screen (1.4), the derivative $\partial_\nu$ equals $\mp \partial_1 = \mp \partial/\partial x_1$, while the standing wave (1.29) does not depend on the longitudinal coordinate $x_1$.

1.4. Literature review. The first example of a (non-embedded) eigenvalue belonging to the discrete spectrum of a problem on oblique waves for a submerged circular cylinder was proposed in [27]. An eigenvalue embedded in the continuous spectrum was constructed in [12] by means of the semi-inverse method. The results in these pioneering papers were obtained by analytic calculations, and they have inspired many other publications with analytic, operator theoretic, or numerical methods (see the reviews in [13] and [14]). In particular, the existence of eigenvalues below the continuous spectrum has been verified with the help of a comparison principle in the paper [28], which also extends the results of [27] to a cylinder with an arbitrary cross-section with positive area.

In the paper [18] the existence of an embedded eigenvalue is shown in the cases of a two-dimensional deep water-domain and a three-dimensional channel, which is similar to the one in the present work, but instead of a thin screen contains a massive body as an obstacle. In both cases the problem is assumed to have the geometric symmetry $1^\circ–2^\circ$, which concerns both the water container and the submerged or surface-piercing body. We remark that by the results of [18], an absolutely flat ($h = 0$) transversal screen (1.4) does not support a trapped mode, but its inclination does. More accurate information on the trapping for small inclination angles in the two-dimensional case is obtained in [30] by using asymptotic analysis. The result on the flat screen cannot directly be obtained from [27], [28], because the volume of $\Theta^\varepsilon$ vanishes at $h = 0$.

In comparison with the present work, [18] cannot yield a uniqueness statement or precise information of the position of the embedded eigenvalue $\lambda^\varepsilon$, since it does not include the elaborate asymptotic construction and matching of the outer and inner expansions of the eigenfunction $u^\varepsilon$ and the resulting asymptotic formulas for $\lambda^\varepsilon$. The approach in the references relies upon a reformulation of the water-wave problem as a self-adjoint operator in a specific Hilbert space and an application of the max-min-principle, see e.g. [2, Thm. 10.2.2.] and [26]. This method has given rather simple proofs of known facts and also new results; the reason is mainly that in certain geometric situations it is possible to construct trial functions, which help to evaluate properly the Rayleigh quotient in the max-min-principle. In this paper, these approximations of eigenvalues and eigenfunctions are made much more precise by perfecting the mentioned method with the help of asymptotic analysis. In Section 6.1 we shall make some further remarks on the relations of [18] and the present work.

In addition to the above described approach of [6], which requires the symmetry conditions $1^\circ$ and $2^\circ$, there exists another method [20, 22] to detect embedded eigenvalues. This is based on the asymptotic analysis of the so-called augmented scattering matrix, which provides a criterion for the existence of trapped modes. This approach does not require the symmetry of the domains $\pi$, $\theta$, or the evenness of the profile functions $h_{\pm}$. Instead, it uses the natural instability of embedded eigenvalues (indeed, their position is sensitive even to small changes of the geometry of the problem domain) and performs a very fine tuning of several geometric parameters of the screen shape in order to keep an eigenvalue in the continuous
spectrum. We emphasize that the embedded eigenvalue \( \lambda^e \) of this paper (see (2.1), (2.31), (3.2), (3.25)) is stable, when \( h_\pm \) are perturbed with functions even in \( x_2 \), but asymmetric perturbations may lead \( \lambda^e \) out of the spectrum and turn it into a point of complex resonance, cf. [1, 21].

The method of matched asymptotic expansions, cf. [29, 9] will be employed in Sections 2 and 3 by applying the interpretation of [19, 20]. Related asymptotic procedures have also been used in [8, 7, 19, 3, 4] etc. to describe asymptotic behaviour of eigenvalues in cylindrical waveguides with small regular and singular perturbations, but these works differ from the present one, since in our case the obstacle is not small in \( x_2 \) and \( z \)-directions.

Methods of asymptotic analysis are also used in the paper [30], which treat problems for two-dimensional water-wave and acoustic waveguides with screens similar to this paper. However, the present work is quite different in several aspects; let us conclude this section by discussing these.

First of all, the flat screen (1.4), which is the defect in the reference waveguide \( \Omega^0 = \Pi \setminus \Theta^0 \) is still large in the sense that it is not contained in a ball of radius \( \varepsilon \), contrary to the previous citation.

As usual, a more simple ansatz and other technical reasons imply that asymptotic analysis is much simpler in dimension 2. This in particular makes it possible in [30] to control the boundary layer terms of the asymptotic ansätze (describing the eigenfunction in the vicinity of the obstacle) for fairly general linear screens. Corresponding boundary layers have not been investigated yet in dimension 3, nor can we present their structure here. Thus, we unfortunately have to accept the restriction 3°: this makes the edge of the screen

\[
\Psi = \{ x : x_1 = 0, x' \in \psi \}
\]

dihedral or cuspidal, see Fig. 1.2.b-d, but it also makes the boundary layer effect to lose its significance. We refer to Section 6.2 of the present paper for a discussion on the boundary layer phenomenon in some special cases and also to [15, Part IV] for particular results.

Second, we deal with screens which pierce the free surface, Fig. 1.2.b, and abut the walls and bottom, Fig. 1.2.d, while in [30] the screen is situated inside the channel, Fig. 1.2.c. Note that in the case of a surface-piercing screen \( \Theta^e \) we are able to single out shapes, which do not support trapped modes for any \( \lambda^e \in (0, \Lambda^\dagger) \), while screens which always trap a wave are outlined in Fig. 1.2.c,d.

Third, although the sharp edge (1.30) of the screen causes singular behaviour of the velocity potential \( u^e \), the assumption 3° enables the use of asymptotic methods generated by regular perturbations of the boundary.

Finally, we shall find two different types of asymptotic expansions of the eigenvalue (1.11), which depend on some integral characteristics of the screen and which are in full agreement with the sufficient condition for the existence of trapped modes, see Section 6.1. In this way the sufficient condition of [18] becomes also a necessary one for a small \( \varepsilon \).

2. Asymptotic analysis. Non-degenerate case

2.1. Outer expansions. In this section we propose an asymptotic representation for an eigenvalue \( \lambda^e \) of (1.15)–(1.18) under the assumption that the integral characteristic \( I(h) \), (2.28), below, does not vanish. We shall establish the asymptotic
Perturbation theory of linear operators, see e.g. [10, Ch. 6], yields the representations

\[ \lambda^\varepsilon = \Lambda^\varepsilon - \varepsilon^2 \lambda_0 + \tilde{\lambda}^\varepsilon, \]

and find a sufficient condition for the crucial property \( \lambda_0 > 0 \) (see Theorem 1.1). The estimate \( |\tilde{\lambda}^\varepsilon| \leq c_1 \varepsilon^{5/2} \) for the remainder will be obtained in Section 5.4.

We assume the following asymptotic ansatz for a trapped wave:

\[ u^\varepsilon(x) = c_\pm(\varepsilon)e^{\mp \mu(\varepsilon)x_1}V(\varepsilon; x') + \ldots, \pm x_1 \gg 1. \]

This involves exponential waves in the intact channel (1.1) at the spectral parameter (2.1), while the screen effects the expansion only through the coefficients \( c_\pm \), which have the Taylor expansion \( c_\pm(\varepsilon) = c_\pm(0) + \varepsilon c'_\pm(0) + O(\varepsilon^2) \). The dots in (2.2) stand for higher order terms, and the couple \( \{\mu(\varepsilon), V(\varepsilon; x')\} \) is a solution of the following problem in a two-dimensional domain,

\[ -\Delta V(\varepsilon; x') = \mu(\varepsilon)^2 V(\varepsilon; x'), \quad \lambda' \in \omega_r, \]

\[ \partial_n V(\varepsilon; x') = 0, \quad V(\varepsilon; x') = 0, \quad x' \in v, \quad \partial_z V(\varepsilon; x') = \lambda^\varepsilon V(\varepsilon; x'), \quad x' \in \gamma_r. \]

Perturbation theory of linear operators, see e.g. [10, Ch. 6], yields the representations

\[ \mu(\varepsilon) = 0 + \varepsilon \mu_0 + \tilde{\mu}(\varepsilon), \quad V(\varepsilon; x') = U_1(x') + \varepsilon^2 V_0(x') + \tilde{V}(\varepsilon; x') \]

(\( U_1 \) as in (1.24)) the following problem for the correction terms in (2.4),

\[ -\Delta' V_0(x') = \mu_0^2 U_1(x'), \quad \lambda' \in \omega_r, \]

\[ \partial_n V_0(x') = 0, \quad V_0(x') = 0, \quad x' \in v, \]

\[ \partial_z V_0(x') = \Lambda_1 V_0(x') - \lambda_0 U_1(x'), \quad x' \in \gamma_r, \]

as well as the error estimates

\[ |\tilde{\mu}(\varepsilon)| \leq c \varepsilon^2, \quad \|\tilde{V}(\varepsilon, \cdot); H^1(\omega_r)\| \leq c \varepsilon^3. \]

We mention that (2.3) is obtained by inserting the exponential waves \( e^{\mp \mu(\varepsilon)x_1}V(\varepsilon, x') \) into the problem (1.15)–(1.18), while (2.5)–(2.7) follows by substituting (2.1), (2.4) into (2.3) and extracting terms of order \( \varepsilon^2 \).

Since \( \Lambda_1 \) is a simple eigenvalue of the \( \square \) model problem (1.19)–(1.22) in \( \omega_r \), the Fredholm alternative yields only one compatibility condition, which by the Green formula turns into

\[ \mu_0^2 \int_{\omega_r} |U_1(x')|^2 d\lambda' = - \int_{\omega_r} (U_1(x')\Delta' V_0(x') - V_0(x')\Delta U_1(x')) d\lambda' \]

\[ = \int_{\partial \omega_r} (V_0(x')\partial_n U_1(x') - U_1(x')\partial_n V_0(x')) d\lambda' = \lambda_0 \int_0^l |U_1(x_2, 0)|^2 dx_2. \]

This was obtained by taking into account the differential equations (1.19) and (2.5) as well as the boundary conditions (1.20)-(1.22) and (2.6), (2.7). Moreover, according to the normalization condition (1.24) we have

\[ \mu_0 = \| U_1; L^2(\omega_r) \|^{-1} \lambda_0^{1/2}. \]

As a consequence, the outer expansions (2.2) looks as follows:

\[ u^\varepsilon(x) = c_\pm(0)U_1(x') + \varepsilon(c'_\pm(0)U_1(x') \mp c_\pm(0)\mu_0 x_1 U_1(x')) + \ldots, \pm x_1 \gg 1. \]
2.2. Inner expansion. In a bounded part of the channel $\Omega_r^\varepsilon$, e.g. near the screen $\Theta^\varepsilon$, we can take a traditional expansion for a trapped mode:

$$u^\varepsilon(x) = v_0(x) + \varepsilon v_1(x) + \ldots,$$

where the dots indicate terms of order at most $O(\varepsilon^2)$. The matching procedure, cf. [29, 9, 19, 20], requires that the behaviour of $v_0(x)$ and $v_1(x)$ as $x_1 \to \pm \infty$ is given by the similar terms in (2.10). Thus, as the first step we notice that $v_0$ behaves at infinity as the standing wave $U_\uparrow$, that is,

$$v_0(x) = c_{\pm}(0)U_\uparrow(x') + \ldots \text{ for } x_1 \to \pm \infty.$$

Recalling the solution (1.29) of the limit problem (1.25)–(1.28), we have to set

$$c_{\pm}(0) = 1 \text{ and } v_0(x) = U_\uparrow(x').$$

To derive a problem for the correction term $v_1$ in (2.11) we first observe that passing to the limit $\varepsilon \to 0^+$ flattens the curved screen $\Theta^\varepsilon$ into the planar one $\Theta^0$, cf. formulas (1.3) and (1.4). Hence, the equation (1.15) in $\Omega$ and the Neumann condition (1.16) on $\Sigma^\varepsilon_r$ yield

$$-\Delta v_1(x) = 0, \ x \in \Omega,$$

and

$$-\partial_\nu v_1(x) = 0, \ x \in \Sigma^\varepsilon_r,.$$

In the same way, the artificial Dirichlet condition (1.18) turns into

$$v_1(x) = 0, \ x \in \Gamma^0,$$

while the spectral condition (1.17) gains the threshold parameter because of the relation $\lambda^\varepsilon = \Lambda_\uparrow + O(\varepsilon^2)$, so that

$$-\partial_\nu v_1(x) = \Lambda_\uparrow v_1(x), \ x \in \Gamma^0_r.$$

It remains to transfer the Neumann condition (1.16) from the curved surfaces $\theta^\varepsilon_{\pm,r}$ onto the flat ones $\theta^0_{\pm,r}$. To do so, we recall definition (1.3) and write the representation

$$v^\varepsilon_{\pm}(x') = (1 + \varepsilon |\nabla' h_{\pm}(x')|)^{-1/2} (\pm 1, \varepsilon \nabla' h_{\pm}(x'))$$

for the unit normal vector. Hence,

$$\left(1 + \varepsilon^2 |\nabla' h_{\pm}(x')|^2\right)^{1/2} v^\varepsilon_{\pm} = \mp \partial_1 + \varepsilon \nabla' h_{\pm}(x') \cdot \nabla',$nabla' = (\partial_2, \partial_3), \partial_1 = \partial/\partial x_1$$

where $\nabla' = (\partial_2, \partial_3), \partial_1 = \partial/\partial x_1$ and the central dot stands for the scalar product in $\mathbb{R}^2$. This and the Taylor formula with respect to $x_1$ yield

$$(1 + \varepsilon^2 |\nabla' h_{\pm}(x')|^2)^{1/2} v_{\pm} = \mp \partial_1 v(\pm \varepsilon h_{\pm}(x'), x') + \varepsilon \nabla' h_{\pm}(x') \cdot v(\pm \varepsilon h_{\pm}(x'), x')$$

$$= \partial_1 v(\pm \varepsilon h_{\pm}(x'), x') - \varepsilon h_{\pm}(x') \partial^2_1 v(\pm \varepsilon h_{\pm}(x'), x')$$

Finally, inserting (2.11), (2.12) into (2.18) and extracting terms $O(\varepsilon)$ yield the following Neumann conditions on the faces $\theta^0_{\pm,r}$ of the planar screen $\Theta^0_r$:

$$\mp \partial_1 v_1(\pm 0, x') = -\nabla' h_{\pm}(x') \cdot \nabla' U_\uparrow(x'), \ x' \in \theta_r.$$
2.3. Solutions of the limit problem at threshold and the matching procedure. As mentioned in the beginning of Section 2.2, the behaviour of the correction term \( v_1(x) \) as \( x_1 \to \pm \infty \) in the inner expansion (2.11) is to be matched with the coefficients of \( \varepsilon \) in the outer expansion (2.10). Thus, we need a solution \( v_1 \) of (2.13)–(2.16), (2.19) with linear growth at infinity. We shall next find this and then perform the matching, which will yield a formula for the number \( \lambda_0 \) in (2.1).

To construct \( v_1 \) we observe that in addition to the solution (1.29) (even in \( x_1 \)), the limit problem (1.25)–(1.28) in \( \Omega^1_r \) has a solution, which is odd in \( x_1 \) and has the representation

\[
(2.20) \quad u^{(1)}(x) = \tilde{u}^{(1)}(x) + \sum_{\pm} \chi_{\pm}(x_1)(x_1 \pm b)U_1(x'),
\]

where the remainder \( \tilde{u}^{(1)}(x) \) decays exponentially as \( x_1 \to \pm \infty \), \( b \) is a constant depending on \( \varpi, \theta \), and \( \chi_{\pm} \) are smooth cut-off functions such that

\[
(2.21) \quad \chi_{\pm}(x_1) = 1 \text{ for } \pm x_1 > 2, \quad \chi_{\pm}(x_1) = 0 \text{ for } \pm x_1 < 1, \quad 0 \leq \chi_{\pm} \leq 1.
\]

There are no other solutions with at most polynomial growth at infinity. These facts follow from general results of the elliptic theory in domains with cylindrical outlets to infinity, see e.g. [23, Ch. 5]. They can also be obtained using the Fourier method by reducing the problem (1.25)–(1.28) to the quarter

\[
(2.22) \quad \Pi_{r,+} = \{ x \in \Pi : x_1 > 0, x_2 > 0 \}
\]

of \( \Pi \) and imposing either the Neumann condition (even case) or the Dirichlet condition (odd case) on the subset \( \{ x : x_1 = 0, x' \in \varpi_r \setminus \overline{\varpi}_r \} \) of the end of the semi-infinite cylinder (2.22).

By similar arguments we can find out that the problem (2.13)–(2.16), (2.19) in \( \Omega \) has a solution \( v_1 \) with linear growth at infinity. Since it is only defined up to a linear combination \( c_0u^{(0)} + c_1u^{(1)} \), we may choose the coefficients \( c_0, c_1 \) such that

\[
(2.23) \quad v_1(x) = \tilde{v}_1(x) + \sum_{\pm} \chi_{\pm}(x_1)(b_1^1|x_1| \pm b_1^0)U_1(x'),
\]

see (1.29), (2.20). The remainder \( \tilde{v}_1(x) \) decays exponentially and the coefficients \( b_1^1, b_1^0 \) are now uniquely defined. We do not need an explicit expression for \( b_1^0 \), and concerning this coefficient we thus only note that in the special case \( h_+ = h_- \) in (2.19), the function (2.23) is even in \( x_1 \) and therefore \( b_1^0 = 0 \).

Let us compute \( b_1^1 \). We insert \( v_1 \) and \( u^{(0)} \) into the Green formula on the truncated channel \( \Omega^0_r(R) = \{ x \in \Omega_r : |x_1| < R \} \) and obtain,

\[
0 = \int_{\partial \Omega^0_r(R)} (U_1(x') \partial_{x'} v_1(x) - v_1(x) \partial_{x'} U_1(x')) ds_x \\
= \sum_{\pm} - \int_{\partial_r} U_1(x') \nabla' h_{\pm}(x') \cdot \nabla' U_1(x') dx' + \sum_{\varpi_r} \pm \int_{\varpi_r} U_1(x') \partial_{x'} v_1(\pm R, x') dx'
\]

\[
(2.24) = - \int_{\partial_r} U_1(x') \nabla' h(x') \cdot \nabla' U_1(x') dx' + 2b_1^1 \int_{\varpi_r} |U_1(x')|^2 dx' + o(1)
\]

as \( R \to +\infty \). Here we have used the boundary conditions on \( \partial \Omega^0_r \), in particular (2.19), and the asymptotic expansion (2.23) at \( x_1 = \pm R \). Passing to the limit
\( R \rightarrow +\infty \) in (2.24) yields

\[
(2.25) \quad b_1^1 = -\frac{1}{2} \| U; L^2(\varpi_r) \|^{-2} I(h),
\]

where we have after integration by parts

\[
(2.26) \quad I(h) = \int_{\partial \theta_r} h(x') U_1(x') \partial_\nu U_1(x') ds_{x'},
\]

The first integral on the right vanishes due to (1.19), and our assumption 3\( \circ \) reduces the last term to an integral over the set

\[
(2.27) \quad \phi_r = \gamma_r \cap \partial \theta_r
\]

(3.2)

\[
(3.1) \quad b_1^1 = 0 \quad \text{and} \quad \lambda_0 = 0, \mu_0 = 0.
\]
The linear growth of the solution (2.23) of the problem (2.13)–(2.16), (2.19) is lost and thus the matching, performed in the last section, fails. As we still want to ensure the inclusion $\lambda^\varepsilon \in (0, \Lambda_\varepsilon)$, we amend the ansatz (2.1) by setting

$$\lambda^\varepsilon = \Lambda_\varepsilon - \varepsilon^4 \lambda_1 + \tilde{\lambda}^\varepsilon, \lambda_1 > 0.$$  

We also have to modify the ansätze (2.4) as follows:

$$\mu(\varepsilon) = 0 + \varepsilon^2 \mu_1 + \tilde{\mu}(\varepsilon), \ V(\varepsilon, \mathbf{x}') = U_1(\mathbf{x}') + \varepsilon^4 V_1(\mathbf{x}') + \tilde{V}(\varepsilon; \mathbf{x}')$$

Accordingly, estimates (2.8) must turn into

$$\text{(3.4)} \quad |\tilde{\mu}(\varepsilon)| \leq c\varepsilon^4, \quad \|\tilde{V}(\varepsilon, \cdot); H^1(\mathcal{W}_\varepsilon)\| \leq c\varepsilon^6.$$  

The pair $\{\mu_1, V_1\}$ in (3.3) satisfies the problem (2.5)–(2.7), which is again derived from (2.9) with evident changes. The compatibility condition in this problem is converted into the relation

$$\mu_1 = \|U_1; L^2(\mathcal{W}_\varepsilon)\|^{-1} \lambda_1^{1/2}.$$  

Finally, applying the above mentioned modifications to the outer expansions (2.2) results in the following ansatz,

$$u^\varepsilon_0 = c(0)U_1(\mathbf{x}') + \varepsilon c^\prime_1(0)U_1(\mathbf{x}') + \varepsilon^2 \left(c^\prime_2(0)U_1(\mathbf{x}') \mp c(0)\mu_1 x_1 U_1(\mathbf{x}')\right) + \ldots, \quad \pm x_1 >> 1.$$  

Then, the inner expansion (2.11) becomes

$$u^\varepsilon_0(\mathbf{x}) = v_0(\mathbf{x}) + \varepsilon v_1(\mathbf{x}) + \varepsilon^2 v_2(\mathbf{x}) + \ldots.$$  

3.2. First asymptotic terms. Let us derive formulae for the terms $v_1$ and $v_2$ in (3.7). The equations (2.12) still hold, and they can be obtained in the same way as in Section 2.2. Moreover, as was noticed in (3.7), the coefficient (2.25) in the decomposition (2.23) vanishes so that the function $v_1$ is reduced to

$$v_1(\mathbf{x}) = \tilde{v}_1(\mathbf{x}) + \sum_{\pm} \pm \chi_{\pm}(x_1)b^0_{\pm}U_1(\mathbf{x}').$$

Matching the multiplier of $\varepsilon$ in (3.6) with the corresponding term in (3.8) gives the second relation in (2.29).

Let us compose a boundary value problem in $\Omega^\varepsilon_1$ for the term $v_2$ in (3.7). Of course this function satisfies the differential equation (2.13) and the boundary conditions (2.14)–(2.16), when the subscripts are changed from 1 to 2. To derive the boundary conditions on the faces $\theta^0_{\pm, r}$, we refine the decomposition (2.18) and write

$$\left(1 + \varepsilon^2|\nabla' h_\varepsilon(\mathbf{x}')|^2\right)^{1/2} \partial_\varepsilon \nabla' \left(v_0(\mathbf{x}') + \varepsilon v_1(\pm \varepsilon h_\varepsilon(\mathbf{x}'), \mathbf{x}') + \varepsilon^2 v_2(\pm \varepsilon h_\varepsilon(\mathbf{x}'), \mathbf{x}')\right)$$

$$= 0 + \varepsilon\left(\pm \partial_1 v_2(\pm 0, \mathbf{x}') + \nabla' v_1(\pm 0, \mathbf{x}') - h_\varepsilon(\mathbf{x}') \partial^2_1 v_1(\pm 0, \mathbf{x}')\right) + \ldots;$$  

the desired boundary condition for $v_2$ follows from the requirement that in (3.9), terms of order $O(\varepsilon^2)$ or larger must vanish. Since the coefficient of $\varepsilon$ is null due to (2.19), it is enough to annul the coefficient of $\varepsilon^2$ in (3.9) by imposing the Neumann conditions

$$\pm \partial_1 v_2(\pm 0, \mathbf{x}') = -\nabla' h_\varepsilon(\mathbf{x}') \cdot \nabla' v_1(\pm 0, \mathbf{x}') - h_\varepsilon(\mathbf{x}') \Delta' v_1(\pm 0, \mathbf{x}')$$

$$= -\nabla' \cdot \left(h_\varepsilon(\mathbf{x}') \nabla' v_1(\pm 0, \mathbf{x}')\right), \mathbf{x}' \in \theta_r.$$
Thus, the function \( v_2 \) is determined from the problem (2.13), (2.14)–(2.16) (with the above mentioned change of the index), and (3.10).

3.3. Properties of the singularities of the solutions. The boundary value problems under consideration have been posed on domains with corner points and edges, which may cause singular behaviour for their solutions. Actually, some of our geometric assumptions in Section 1 were made in order to reduce the influence of the singularities to the asymptotic procedure.

First of all we mention that the eigenfunction \( U_1 \) of the problem (1.19)–(1.22) is infinitely differentiable everywhere in \( \overline{\Omega} \), because the arc \( \zeta \) is smooth and meets the \( x_2 \)- and \( x_3 \)-axis at the right angle. A reason for the exclusion of the singularities can be found, e.g., in [23, §2.4].

The behaviour of the solution \( v_1 \) of the problem (2.13)–(2.16), (2.19) near the edge \( \Psi \), which may be quite complicated because of the endpoints of the arc \( \psi_r \), which are tops of polyhedral angles. As known e.g. by [23, Ch. 10, Ch. 11], the behaviour of \( v_1 \) in the interior of \( \Psi \) is determined by the functions

\[
K_j(s) r^{j/2} \cos(j \varphi/2), \quad j = 0, 1, 2, \ldots,
\]

where \( s \in (0, L) \) is the arc length along \( \Psi \) such that \( s = 0 \) and \( s = L \) correspond to the tops of the polyhedral angles, and \( (r, \varphi) \in \mathbb{R}_+ \times (0, 2\pi) \) is the polar coordinate system in planes, which are perpendicular to \( \Psi \). The function (3.11) with \( j = 0 \) is smooth so that the main singularities of the derivatives of \( v_1 \) are produced by \( K_1(s) r^{1/2} \cos(\varphi/2) \). The coefficient function \( K_1 \) is called the intensity factor in the mechanics of solids, and since the data (the right hand side and the curve \( \partial \theta \)) in (2.19) is infinitely differentiable, it belongs to \( C^\infty(0, L) \). However, \( K_1 \) may become singular at the tops \( s = 0 \) and \( s = L \) of the polyhedral angles.

As for the point \( s = 0 \), which is marked by \( \bullet \) in Fig. 1.1.b, the function \( K_1 \) is smooth there, since \( v_1 \) can be extended as an odd function with respect to \( x_2 \) from \( \Omega^0 \) onto \( \Omega^0 \) (recall the artificial Dirichlet condition): such an extension preserves the differentiability properties of the data and renders the point in the middle of the smooth edge \( \Psi \). However, \( K_1 \) may be only Hölder-continuous at the point \( s = L \) which is marked by \( \blacksquare \) in Fig. 1.1.b; that is, \( K_1 \in C^{0, \delta}(0, L) \) for any \( \delta \in (0, 1) \), while

\[
|\partial^p K_1(s)| \leq C(L - s)^{1-p}, \quad p = 0, 1, 2, \ldots.
\]

Let us explain this last fact. According to the general procedure, e.g. [23, Ch. 10, Ch. 11], the asymptotic expansion of \( v_1 \) near the endpoint of \( s = L \) of the edge \( \Psi \) includes the power-law solutions

\[
\phi^\beta \phi(\vartheta)
\]

of the Laplace-Neumann problem in the polyhedron \( \mathbb{K} \), which is the complement of the quadrant \( \{x : x_1 = 0, x_2 > x_2^0, x_3 < 0\} \) in the lower half-space. In (3.13), \( (\varrho, \vartheta) \) are the polar coordinates, \( \beta \) is a real number specified below, and \( \phi \) is a function in the lower hemisphere without half of the meridian, Fig. 3.1.b. We extend this model problem evenly with respect to \( x_1 \) through the horizontal plane, and this turns it into the Neumann problem in the domain, which is the full space \( \mathbb{R}^3 \) with unbounded incision of the shape of the half-plane. The power-law solutions (3.13) with non-negative exponents \( \beta \) of this problem look like

\[
\phi_{k/2}(\vartheta) = r^{k/2} \cos(\pi k/2), \quad k = 0, 1, 2, \ldots,
\]
EMBEDDED EIGENVALUES FOR WATER-WAVES

Figure 3.1. Hemisphere with incision.

cf. (3.11). In this way the extension turns the endpoint \( s = L \) into an interior point of a smooth edge. At the same time the Neumann boundary condition on the plane \( \{ x : z = 0 \} \) (the horizontal one in Fig. 3.1.a) was obtained by neglecting the term \( \Lambda_1 v_1 \) in the Steklov condition (2.16). Thus, there emerges a discrepancy, the main term of which is \( \Lambda_1 K_1(L) r^{1/2} \cos(\varphi/2) \), and this has to be compensated by a solution of the following model problem in \( \mathbb{K} \):

\[
\frac{\varphi^{3/2}}{2} \left( C_0 \phi_3(\vartheta) \ln \varrho + \phi'_3(\vartheta) \right)
= \frac{1}{2} C_0 r^{3/2} \ln(r^2 + z^2) \cos \left( \frac{3}{2} \varphi \right) + (r^2 + z^2)^{3/4} \phi'_3(\vartheta).
\]

The first term on the right (with \( \cos(3\varphi/2) \)) does not affect the singularity of (3.11) (which is \( \cos(\varphi/2) \) anyway), but the second term may cause a peculiar behaviour of \( K_1(s) \) as \( s \to L - 0 \), and this is apparent in the estimates (3.12).

The asymptotic expansion of \( v_1 \) could be studied further, in particular it would be possible to verify that the derivative \( \partial_s K_1 \) is Hölder continuous. However, this would require a much more elaborate analysis, while the information contained in (3.12) suffices in order to conclude that the problem (2.13)–(2.16), (3.10) has a solution which belongs to \( H^1(\Omega^0_\rho) \) for any \( R > 0 \). The inclusion \( v_2 \in H^1_{loc}(\Omega^0_\rho) \) is obtained from the Hardy-type inequality

\[
\int_{\theta^1_{\pm, \rho}} r^{-1} (1 + |\ln r|)^{-2} |w(0, x')|^2 dx' \leq c \int_{\Omega^0_\rho(R)} (|\nabla w(x)|^2 + |w(x)|^2) dx,
\]

and the weak formulation of the problem in a weighted space with detached asymptotics, cf. [23, Ch. 6]. Instead of using these involved techniques one may directly observe that the right hand sides \( g_{\pm}(x') \) in (3.10) satisfy the bound \( |g_{\pm}(x')| \leq cr^{-1/2}(1 + r/\varrho) \) as a consequence of the assumption 3°.

We shall return to a discussion on the singularities in Section 6.3 and now finalize our consideration by writing down the following expansion near the edge:

\[
v_1(x) = \tilde{v}_1(x) + K_0(s) + K_1(s) r^{1/2} \cos(\varphi/2).
\]

Here, \( K_0 \in C^\infty[0, L] \), \( K_1 \) belongs to \( C^\infty[0, L] \) and satisfies (3.12), and the remainder satisfies the estimates

\[
r^{-1} |\tilde{v}_1(x)| + |\nabla \tilde{v}_1(x)| \leq C,
\]

\[
|\nabla^p \tilde{v}_1(x)| \leq cr^{-p+3/2}(1 + |\ln(L - s)|), \quad p = 2, 3, \ldots
\]
for small \( r > 0 \). Notice that the first of these estimates follow from the smooth term 
\( K_2(s) r^1 \cos(\varphi) \), see (3.11) with \( j = 2 \), but the last one indicates the singularities 
\( K_3(s) r^{3/2} \cos(3\varphi/2) \) and (3.15). We emphasize that the singularities in (3.17) and 
(3.18) satisfy the traditional Meixner condition [16] mentioned in Section 1.1.

3.4. Asymptotics of \( v_2 \) at infinity. We next apply the approach of Section 2.3 to 
find the term of \( v_2 \) with linear growth as \( x_1 \to \pm \infty \). Indeed, the determining 
problem for the function \( v_2 \), i.e. (2.13)–(2.16), (3.10), is the same as that for \( v_1 \) 
except for the last boundary condition, which is (2.19) for \( v_1 \) instead of (3.10) for 
\( v_2 \). However, the right hand sides of these two conditions differ only in the compact 
set \( \theta_r \), and we can conclude that \( v_2 \) admits the same representation (2.23) as \( v_1 \):

\[
(3.19) \quad v_2(x) = \tilde{v}_2(x) + \sum_{\pm} \chi_{\pm}(x_1) (b_2^1 |x_1| \pm b_2^0) U_1(x').
\]

Let us compute the coefficient \( b_2^1 \). Using integration by parts inside \( \Omega^0_\nu(R) \) and along 
\( \theta^0_{\pm, r} \), we obtain, similarly to (1.12),

\[
2b_2^1 \int_{\partial \omega_R} |U_1(x')|^2 \, dx' = \lim_{R \to +\infty} \sum_{\pm} \int_{\partial \omega_R} U_1(x') \partial_1 v_2(\pm R, x') \, dx'
\]

\[
= \sum_{\pm} \int_{\partial \omega_R} U_1(x') \partial_1 v_2(\pm R, x') \, dx'
\]

\[
= \sum_{\pm} \int_{\partial \omega_R} U_1(x') \nabla' \cdot (h_{\pm}(x') \nabla' v_1(\pm 0, x')) \, dx'
\]

\[
= \sum_{\pm} \left( -\int_{\partial \omega_R} h_{\pm}(x') \nabla' U_1(x') \cdot \nabla' v_1(\pm 0, x') \right) \, dx'
\]

\[
+ \int_{\partial \omega_R} h_{\pm}(x_2, 0) U_1(x_2, 0) \partial_z v_1(\pm 0, x_2, 0) \, dx_2
\]

\[
= \sum_{\pm} \left( \int_{\partial \omega_R} v_1(\pm 0, x') \nabla' h_{\pm}(x') \cdot \nabla' U_1(x') \, dx'
\]

\[
+ \int_{\partial \omega_R} v_1(\pm 0, x') h_{\pm}(x') \Delta' U_1(x') \, dx'
\]

\[
(3.20) \quad + \int_{\partial \omega_R} h_{\pm}(x_2, 0) \left( U_1(x_2, 0) \partial_z v_1(\pm 0, x_2, 0) - v_1(\pm 0, x_2, 0) \partial_z U_1(x_2, 0) \right) \, dx_2.
\]

The last and second but last integrals vanish, due to the Steklov conditions (1.21), 
(2.16) and the Laplace equation (1.19), respectively. Hence, similarly to (2.25), we have

\[
(3.21) \quad b_2^1 = -\frac{1}{2} ||U_1; L^2(\omega_R)||^{-2} J(h),
\]

where \( J(h) \) is obtained by taking (2.19) into account and integrating by parts in \( \Omega^0_\nu \):

\[
J(h) = \sum_{\pm} \int_{\partial \omega_R} v_1(\pm 0, x') \partial_1 v_1(\pm 0, x') \, dx'.
\]
We emphasize that the representation (3.8) of the bounded solution \( v_1 \) guarantees that the integrand

\[
\int_{\mathbb{R}} \left( \int_{\mathbb{R}} |\nabla v_1(x')|^2 dx' - \Lambda_\dagger \int_0^l |v_1(x_1, x_2, 0)|^2 dx_2 \right) dx_1.
\]

(3.22)

decays exponentially at infinity: in view of (1.19)–(1.22), we have \( j(U_\dagger) = 0 \) and hence, constant terms become null in the asymptotics of (3.23) as \( x_1 \to \pm \infty \). It is worth mentioning that the convergence of all integrals in (3.20) follows from the material in Section 3.3.

3.5. Asymptotics of the eigenvalue. In Section 4.1 we shall verify that the inequality

\[
J(h) > 0
\]

(3.24)

always holds under the general assumption of our paper. We are now in position to complete the matching procedure and to derive a formula for the correction term in (3.2). Recalling the conclusions (2.12) and (2.29) we compare linear terms in the coefficients of \( \varepsilon^2 \) in (3.6) and (3.7). According to (3.5), (3.19), and (3.21) we see that, first, \( \mp \mu_1 = \pm b_2^1 \), and, second,

\[
\|U_\dagger; L^2(\mathbb{R})\|^{-1} \lambda_1^{1/2} = \mu_1 = b_2^1 = \frac{1}{2} \|U_\dagger; L^2(\mathbb{R})\|^{-2} J(h).
\]

Because of (3.24) we can write

\[
\lambda_1 = \frac{1}{4} \|U_\dagger; L^2(\mathbb{R})\|^{-2} J(h),
\]

(3.25)

and formulate the main result on the asymptotics of the embedded eigenvalue in the case of the degenerate integral characteristic. The proof will be completed in Sections 4 and 5.

**Theorem 3.1.** Assume that the conditions 1°–3° hold true and that \( I(h) = 0 \), see (2.28). Then, there exist \( \varepsilon_2 = \varepsilon_2(\theta, h_\pm) > 0 \) and \( c_2 > 0 \) such that the problem (1.8)–(1.10) has for every \( \varepsilon \in (0, \varepsilon_2) \) a unique eigenvalue (3.2) inside the segment \((0, \Lambda_\dagger]\). The correction term \( \lambda_0 > 0 \) is given by (3.25), (3.22) and the asymptotic remainder meets the estimate

\[
|\tilde{\lambda}^\varepsilon| \leq c_2 \varepsilon^{9/2}.
\]

(3.26)

4. Uniqueness of the embedded eigenvalue.

4.1. Absence of trapped modes at the threshold. Section 4 is devoted to the proof of the uniqueness statements in Theorems 1.1 and 3.1. Sections 4.1 and 4.2 contain preliminary results on eigenvalues at the threshold situation and in a truncated water domain. We start by proving that the problem (1.25)–(1.28) has no trapped modes at the threshold \( \Lambda = \Lambda_\dagger \), cf. Section 2.3 and Theorems 1.1, 3.1. Let
$u^0 \in H^1_0(\Omega^0_\epsilon; \Sigma^0)$ be a solution of this homogeneous problem. The Green formula gives

$$\int_{\Omega^0_\epsilon} \left| \frac{\partial u^0}{\partial x_1}(x) \right|^2 dx + \int_{\Omega^0_\epsilon} |\nabla' u^0(x)|^2 dx - \Lambda \int_{\Gamma^0_\epsilon} |u^0(x_1, x_2, 0)|^2 dx_1 dx_2 = 0. \quad (4.1)$$

The max-min-principle (1.23) implies for all $V \in H^1_0(\omega_\epsilon; \nu)$

$$\int_{\Omega^0_\epsilon} |\nabla' V(x')|^2 dx' \geq \Lambda \int_{\gamma^0_\epsilon} V(x_2, 0) dx_2. \quad (4.2)$$

Setting $V(x') = u^0(x_1, x')$ in (4.2) and integrating the result in $x_1 \in (-\infty, 0) \cup (0, +\infty)$ shows that the difference of the second and third integrals in (4.1) is non-negative. Hence,

$$\int_{\Omega^0_\epsilon} |\partial_1 u^0(x)|^2 dx \leq 0$$

and therefore $u^0$ does not depend on the longitudinal variable $x_1$. Owing to the decay of $u^0$ at infinity, this is possible only if $u^0 = 0$.

A similar consideration proves the key inequality (3.24) of Section 3.5. Indeed, we have

$$J(h) = \int_{\Omega^0_\epsilon} \left| \partial_1 v_1(x) \right|^2 dx + \int_{-\infty}^{\infty} j(v_1; x_1) dx_1,$$

where the first integral converges, because the $x_1$-derivative of the function (2.23) decays exponentially. The integrand (3.23) is non-negative due to the inequality (4.2), and thus $J(h) \geq 0$. \hfill \blacksquare \quad \text{The equality } J(h) = 0 \text{ is possible only in the case } \partial_1 v_1 = 0 \text{ in } \Omega^0_\epsilon. \text{ The asymptotic behaviour (3.8) shows that } v_1(x) = \pm b^0 U_\epsilon(x') \text{ for } \pm x_1 > 0, \text{ and due to the continuity of } v_1, \text{ this is possible only if } b^0_\epsilon = 0, \text{ i.e. } v_1 = 0. \text{ But of course, the null function cannot be a solution of the problem (2.13)–(2.16) with inhomogeneous boundary conditions (2.19).}

### 4.2. Asymptotics of eigenvalues in a bounded domain.

In the next section we shall need some information on the eigenvalues of the problem

$$-\Delta w^\epsilon(x) = 0, \quad x \in \Omega^\epsilon_\epsilon(R), \quad (4.3)$$

$$\partial_\nu w^\epsilon(x) = 0, \quad x \in \Sigma_\epsilon^\epsilon(R) \cup \bigcup_{\pm} (\theta^\epsilon_{\epsilon, \tau} \cup \omega_\epsilon(\pm R)), \quad (4.4)$$

$$\partial_\nu w^\epsilon(x) = \beta^\epsilon w^\epsilon(x), \quad x \in \Gamma_\epsilon^\epsilon(R), \quad (4.5)$$

$$w^\epsilon(x) = 0, \quad x \in \Sigma^\epsilon(\pm R), \quad (4.6)$$

in the bounded domain $\Omega^\epsilon_\epsilon(R) = \{ x \in \Omega^\epsilon_\epsilon : |x_1| < R \}$ with some fixed $R > 0$; the sets $\Sigma_\epsilon^\epsilon(R), \Gamma_\epsilon^\epsilon(R)$, and $\Sigma^\epsilon(\pm R)$ are defined similarly. On the truncated cross-sections $\omega_\epsilon(\pm R)$, an artificial Neumann condition is imposed in (4.4), and the other conditions are inherited from (1.16)–(1.18). \hfill \blacksquare \quad \text{Fixing } R, \text{ we next derive an asymptotic formula for the lowest eigenvalue of this problem as } \epsilon \to 0.

Putting $\epsilon = 0$ turns the problem (4.3)–(4.6) into the limit problem in the bounded cylinder $\Pi_\epsilon(R) = (-R, R) \times \omega_\epsilon$ with the incision $\Theta_\epsilon^0$. For this problem, we readily find the eigenvalue $\beta^0_1 = \Lambda$ and the corresponding eigenfunction $w^0_1(x) = U_1(x')$. 
Since $U_\dagger > 0$ in $\varpi_r$, the strong maximum principle shows that this is the first, simple eigenvalue. We shall also need the second eigenvalue

$$\beta_2^0 > \beta_1^0 = \lambda_\dagger,$$

which of course may be multiple.

In view of the assumption $3^\circ$, Section 1.2 and the definition (1.3) of $\Theta^\circ$, there exists a diffeomorphism $\varphi$ of class $H^{1,\infty}$ which transforms $\Omega^\circ_r(R)$ into $\Omega^0_r(R)$ and which is "almost identical",

$$|\varphi^\circ(x) - x| \leq c\varepsilon, \quad \left| \frac{d\varphi^\circ}{dx} - \text{Id} \right| \leq c\varepsilon.$$

According to [10, 7.6.5], see also [23, Ch. 5], this means that $\beta^\circ_\varepsilon = \beta_\varepsilon^0 + O(\varepsilon)$ and in particular

$$\beta_2^\circ > \Lambda_\dagger \text{ for } \varepsilon \in (0, \varepsilon_0]$$

by virtue of (4.8). Let us compute the asymptotics of $\beta_1^\circ$.

In spite of the edge $\Psi$, the transition from $\Theta^\circ_r$ to $\Theta^0_r$ can be regarded as a regular perturbation of the boundary, cf. Section 3.3, and we thus choose the standard ansatz for the eigenvalue and the corresponding eigenfunction

$$\beta_1^\circ = \Lambda_\dagger - \alpha\varepsilon + \tilde{\beta}_1^\circ,$$

$$w_1^\circ(x) = U_\dagger(x') + \varepsilon W(x) + \tilde{w}_1^\circ(x).$$

We insert them into the problem (4.3)–(4.6), repeat the arguments of Section 2.2 and thus obtain the following problem for the correction terms in (4.9):

$$\begin{align*}
-\Delta W(x) &= 0, \quad x \in \Omega^0_r(R), \\
\partial_\nu W(x) &= 0, \quad x \in \Sigma^0_r, \quad \pm \partial_1 W(\pm R, x') = 0, \quad x \in \varpi_r, \\
\pm \partial_1 W(\pm 0, x') &= -\nabla' h_\pm(x') \cdot \nabla' U_\dagger(x'), \quad x' \in \theta_r \\
\partial_1 W(x) &= \Lambda_\dagger W(x) - \alpha U_\dagger(x'), x \in \Gamma^0_r(R), \\
W(x) &= 0, \quad x \in \Gamma^0(R).
\end{align*}$$

Moreover, since the eigenvalue $\Lambda_\dagger$ is simple, the only compatibility condition in this problem reads as

$$0 = \int_{\partial\Omega^0_r} (U_\dagger(x')\partial_\nu W(x) - W(x)\partial_\nu U_\dagger(x'))\, ds_x$$

$$= -\alpha \int_{\Gamma^0_r} |U_\dagger(x_2, 0)|^2 dx_2 \, ds_x - \sum_{\pm} \int_{\theta_r} U_\dagger(x') \nabla' h_\pm(x') \cdot \nabla' U_\dagger(x') \, dx'.$$

Hence, (1.24), (2.26), (2.28) imply

$$\alpha = (2R)^{-1} I(h).$$

Finally, again according to [10, 7.6.5], the remainder in (4.9) can be bounded by

$$|\tilde{\beta}_1^\circ| \leq c\varepsilon^2.$$
4.3. Max-min-principle. We now complete the uniqueness proof by using the methods of [18], which involve the introduction of an abstract linear operator $T^\varepsilon$ in a Sobolev-type Hilbert space and the use of the max-min-principle. We equip the Sobolev-space $H^\varepsilon = H^1_0(\Omega^\varepsilon_r; \Upsilon^\varepsilon)$ with the scalar product
\begin{equation}
\langle u^\varepsilon, v^\varepsilon \rangle = (\nabla u^\varepsilon, \nabla v^\varepsilon)_{\Omega^\varepsilon_r}
\end{equation}
and define the operator $T^\varepsilon$ by the identity
\begin{equation}
\langle T^\varepsilon u^\varepsilon, v^\varepsilon \rangle = (u^\varepsilon, v^\varepsilon)_{\Gamma^\varepsilon_r},
\end{equation}
where $(\cdot, \cdot)_{\Xi}$ stands for the natural scalar product of the Lebesgue space $L^2(\Xi)$. The inequality
\begin{equation}
\|u^\varepsilon; L^2(\Omega^\varepsilon_r)\|^2 + \|u^\varepsilon; L^2(\Gamma^\varepsilon_r)\|^2 \leq c\|\nabla u^\varepsilon; L^2(\Omega^\varepsilon_r)\|^2
\end{equation}
follows from the standard Friedrichs inequality in the truncated channel,
\begin{equation}
\|u^\varepsilon; L^2(\Omega^\varepsilon_p(R))\|^2 + \|u^\varepsilon; L^2(\Gamma^\varepsilon_p(R))\|^2 \leq c\|\nabla u^\varepsilon; L^2(\Omega^\varepsilon_p(R))\|^2,
\end{equation}
and the trace inequality in the cross-section $\varpi$,
\begin{equation}
\|U^\varepsilon; L^2(\varpi_r)\|^2 \leq c\|\nabla'U^\varepsilon; L^2(\varpi_r)\|^2.
\end{equation}
These inequalities are valid owing to the Dirichlet conditions (1.18) and (1.22), respectively. In (4.16) we set $U^\varepsilon(x') = u^\varepsilon(x)$ and in addition integrate over $x_1 \in (-\infty, -R) \cup (R, +\infty)$. The constant $c$ in (4.15) does not depend on $\varepsilon$, since the parts of the surface $\partial \Omega^\varepsilon_r$ which are inside $\Pi_r$ can be considered as graphs of functions in the variable $x'$, cf. [30].

The inequality (4.14) and the definition of the inner product (4.12) imply that the operator $T^\varepsilon$ is continuous, positive, and symmetric, hence, self-adjoint. Moreover, by (4.12) and (4.13), the variational formulation of the problem (1.15)–(1.18),
\begin{equation}
(\nabla u^\varepsilon, \nabla v^\varepsilon)_{\Omega^\varepsilon_r} = \lambda^\varepsilon(u^\varepsilon, v^\varepsilon)_{\Gamma^\varepsilon_r} \quad \forall v^\varepsilon \in H^1_0(\Omega^\varepsilon_r; \Upsilon^\varepsilon),
\end{equation}
can be formulated as the abstract equation
\begin{equation}
T^\varepsilon u^\varepsilon = \tau^\varepsilon u^\varepsilon \quad \text{in } H^\varepsilon,
\end{equation}
with the new spectral parameter
\begin{equation}
\tau^\varepsilon = 1/\lambda^\varepsilon.
\end{equation}
This relation implies that the continuous spectrum of $T^\varepsilon$ is $[0, \Lambda_{\text{th}}^{-1}]$. Moreover, the operator $-T^\varepsilon$ (with the minus sign) is bounded from below and eigenvalues $\tau_1^\varepsilon, \ldots, \tau_N^\varepsilon$ in its discrete spectrum can be obtained from the max-min-principle
\begin{equation}
-\tau_n^\varepsilon = \max_{H^\varepsilon} \min_{0 \neq v^\varepsilon \in H^\varepsilon \setminus \{0\}} \frac{-\langle T^\varepsilon v^\varepsilon, v^\varepsilon \rangle}{\langle v^\varepsilon, v^\varepsilon \rangle},
\end{equation}
where $H^\varepsilon_n$ is any subspace of $H^\varepsilon$ with codimension $n - 1$. More precisely, Theorem 10.2.2. of [2] or Theorem XIII.1 of [26] state that if the right hand side of (4.20) is less than $\Lambda_{\text{th}}^{-1}$, then the discrete spectrum of $T^\varepsilon$ contains at least $n$ points, which thus are isolated eigenvalues. By the relation (4.19) this also means that the discrete spectrum of the problem (1.15)–(1.18) contains at most $n$ points.
Let us assume that $I(h)$, (2.28), is negative. Then, by (4.10) and (4.11), the first eigenvalue (4.9) of the auxiliary problem (4.3)–(4.6) in the bounded domain satisfies $\beta_1 \geq \lambda_1$ for small $\varepsilon \in (0, \varepsilon_0]$ and therefore we have the inequality

$$\|\nabla v^\varepsilon; L^2(\Omega^\varepsilon_r(R))\|^2 \geq \beta_\varepsilon^p \|v^\varepsilon; L^2(\Gamma^\varepsilon_r(R))\|^2.$$  

We take the inequality (4.2) with $V(x') = v^\varepsilon(x_1, x')$, integrate it in $x_1 \in (-\infty, -R) \cup (R, +\infty)$, add it to (4.21) and obtain

$$\|\nabla v^\varepsilon; L^2(\Omega_r)\|^2 \geq \Lambda_1\|v^\varepsilon; L^2(\Omega_r)\|^2.$$  

Thus, for all $v^\varepsilon \in \mathcal{H}^\varepsilon$ we have

$$\frac{-\langle T^\varepsilon v^\varepsilon, v^\varepsilon \rangle}{\langle v^\varepsilon, v^\varepsilon \rangle} = -\frac{\|v^\varepsilon; L^2(\Gamma^\varepsilon_r)\|^2}{\|\nabla v^\varepsilon; L^2(\Omega^\varepsilon_r)\|^2} \geq \frac{1}{\Lambda_1},$$

so that the right hand side of (4.20) with $n = 1$ exceeds $-\lambda_1$.

By the above mentioned theorems of [2] and [26], the discrete spectrum of $T^\varepsilon$ is empty. By the remark after (4.20), this means that the discrete spectrum of the problem (1.15)–(1.18) is empty as well, and as explained above Remark 1.2, this implies that there are no embedded eigenvalues for the problem (1.8)–(1.10) contained in the interval $[0, \Lambda_1]$. The first assertion of Theorem 1.1 has thus been verified.

Let $I(h) \geq 0$. We now deal with the second eigenvalue $\beta_2$ and introduce the subspace of codimension $1$,

$$\mathcal{H}^\varepsilon_{-1} = \left\{ v^\varepsilon \in H^1_0(\Omega^\varepsilon_r; \Gamma^\varepsilon_r) : \int_{\Omega^\varepsilon_r(R)} v^\varepsilon(x)w^\varepsilon_1(x)dx = 0 \right\}.$$  

In (4.24), $w^\varepsilon_1$ is the first eigenfunction of the problem (4.3)–(4.6). Owing to the orthogonality condition in (4.24), any function $v^\varepsilon \in \mathcal{H}^\varepsilon_1$ satisifies the relation (4.21) with $p = 2$, which is an inequality of Poincaré type. We obtain the formula (4.22) by (4.7) and (4.2) and conclude that

$$\inf_{v^\varepsilon \in \mathcal{H}^\varepsilon \setminus \{0\}} \frac{-\langle T^\varepsilon v^\varepsilon, v^\varepsilon \rangle}{\langle v^\varepsilon, v^\varepsilon \rangle} = -\sup_{v^\varepsilon \in \mathcal{H}^\varepsilon \setminus \{0\}} \frac{\|v^\varepsilon; L^2(\Gamma^\varepsilon_r)\|^2}{\|\nabla v^\varepsilon; L^2(\Omega^\varepsilon_r)\|^2} \geq -\frac{1}{\Lambda_1} \geq -\frac{1}{\Lambda_1}.$$  

Once more, the above mentioned theorems of [2] or [26] implies that the discrete spectrum of the operator $T^\varepsilon$ can contain at most one eigenvalue. As in the previous case we deduce that the problem (1.8)–(1.10) can have at most one eigenvalue in the interval $[0, \Lambda_1]$.

The uniqueness statements in Theorems 1.1, (2), and (3.1) have been confirmed.

### 5. Existence of an eigenvalue.

#### 5.1. Searching for an eigenvalue.

We shall construct a non-trivial function $u^\varepsilon_{as} \in H^1(\Omega^\varepsilon_r, v^\varepsilon)$ and find positive numbers $\tau^\varepsilon_{as}, \delta$ such that

$$\|T^\varepsilon u^\varepsilon_{as} - \tau^\varepsilon_{as} u^\varepsilon_{as}, \mathcal{H}^\varepsilon\| = \delta\|u^\varepsilon_{as}, \mathcal{H}^\varepsilon\|,$$

$$\tau^\varepsilon_{as} - \delta > \frac{1}{\Lambda_1^\varepsilon}.$$  

A classical lemma on "approximate eigenvalues", see e.g. [31], and the formulas (5.1), (5.2) guarantee that the segment $[\tau^\varepsilon_{as} - \delta, \tau^\varepsilon_{as} + \delta]$ does not intersect the continuous spectrum $[0, \Lambda_1^\varepsilon]$ and contains an eigenvalue $\tau^\varepsilon_1$ of the operator $T^\varepsilon$. Then,

---

1This inequality is quite similar to (4.2) and both of them can be derived by using a reduction to an abstract equation and applying the min-principle.
the relation (4.19) of the spectral parameters implies the existence of the eigenvalue \( \lambda_1^\varepsilon = 1/\tau_1^\varepsilon \in (0, \Lambda_1) \) of the problem (1.15)–(1.18) and thus of the problem (1.8)–(1.10), as well as the estimate

\[
|\lambda_1^\varepsilon - \lambda_{as}^\varepsilon| \leq C \varepsilon \delta \quad \text{with} \quad \lambda_{as}^\varepsilon = \frac{1}{\tau_{as}^\varepsilon}, \quad C = \frac{\delta}{\tau_{as}^\varepsilon (\tau_{as} - \delta)}.
\]

In the previous section we have proved that an eigenvalue in \((0, \Lambda_1)\) is unique, if it exists. That is why the above mentioned lemma additionally yields an eigenfunction \( u_1^\varepsilon \in H^1_0(\Omega^\varepsilon; \mathcal{V}^\varepsilon) \), which corresponds to \( \lambda_1^\varepsilon \), but is not necessarily normalized in \( \mathcal{H}^\varepsilon \), and satisfies the estimate

\[
\|u_1^\varepsilon - v_{as}^\varepsilon; \mathcal{H}^\varepsilon\| \leq \delta \|u_{as}^\varepsilon; \mathcal{H}^\varepsilon\|.
\]

The simplest way to derive these and similar facts is to apply elementary tools of the theory of the spectral measure; in this way the reduction to the abstract equation becomes very important. In particular, the key estimate

\[
|\tau_1^\varepsilon - \tau_{as}^\varepsilon| \leq \delta
\]

is a consequence of the spectral decomposition of the resolvent, see [2, §6.2], which includes an estimate of the distance of a point to the spectrum in terms of the norm of the resolvent, see (5.1). The estimate (5.4) for the eigenfunction follows by using the spectral projection. A detailed explanation of this technique is given for example in [25].

5.2. **Approximate eigenvalue and eigenfunction.** We assume the condition \( I(h) > 0 \) and set

\[
\lambda_{as}^\varepsilon = \Lambda_1 - \varepsilon^2 \lambda_0
\]

and correspondingly \( \tau_{as}^\varepsilon = (\Lambda_1 - \varepsilon^2 \lambda_0)^{-1} \); here \( \lambda_0 \) is taken from (2.31). Moreover, by \( \{\mu_{as}(\varepsilon), V_{as}(\varepsilon; x')\} \) we understand the solution (2.4) of the model problem (2.3) on \( \varpi_r \) with the spectral parameter (5.6).

We connect the inner and outer expansions (2.11) and (2.2) of Section 2 by using the smooth cut-off functions (2.21) and the function

\[
X_\varepsilon(x_1) = 1 \text{ for } |x_1| < 1/\varepsilon, \quad X_\varepsilon(x_1) = 0 \text{ for } |x_1| > 1+1/\varepsilon, \quad 0 \leq X_\varepsilon \leq 1.
\]

Namely, we set

\[
u_{as}^\varepsilon(x) = X_\varepsilon(x_1)(v_0(x) + \varepsilon v_1(x)) + \sum_{\pm} \chi_{\pm}(x_1)(1 \pm \varepsilon \beta_0^0) e^{\mp \mu(\varepsilon)x_1} V(\varepsilon; x')
\]

and correspondingly

\[
\tau_{as}^\varepsilon = (\Lambda_1 - \varepsilon^2 \lambda_0)^{-1}
\]

is a consequence of the spectral decomposition of the resolvent, see [2, §6.2], which includes an estimate of the distance of a point to the spectrum in terms of the norm of the resolvent, see (5.1). The estimate (5.4) for the eigenfunction follows by using the spectral projection. A detailed explanation of this technique is given for example in [25].

5.2. **Approximate eigenvalue and eigenfunction.** We assume the condition \( I(h) > 0 \) and set

\[
\lambda_{as}^\varepsilon = \Lambda_1 - \varepsilon^2 \lambda_0
\]

and correspondingly \( \tau_{as}^\varepsilon = (\Lambda_1 - \varepsilon^2 \lambda_0)^{-1} \); here \( \lambda_0 \) is taken from (2.31). Moreover, by \( \{\mu_{as}(\varepsilon), V_{as}(\varepsilon; x')\} \) we understand the solution (2.4) of the model problem (2.3) on \( \varpi_r \) with the spectral parameter (5.6).

We connect the inner and outer expansions (2.11) and (2.2) of Section 2 by using the smooth cut-off functions (2.21) and the function

\[
X_\varepsilon(x_1) = 1 \text{ for } |x_1| < 1/\varepsilon, \quad X_\varepsilon(x_1) = 0 \text{ for } |x_1| > 1+1/\varepsilon, \quad 0 \leq X_\varepsilon \leq 1.
\]

Namely, we set

\[
u_{as}^\varepsilon(x) = X_\varepsilon(x_1)(v_0(x) + \varepsilon v_1(x)) + \sum_{\pm} \chi_{\pm}(x_1)(1 \pm \varepsilon \beta_0^0) e^{\mp \mu(\varepsilon)x_1} V(\varepsilon; x')
\]

and correspondingly

\[
\tau_{as}^\varepsilon = (\Lambda_1 - \varepsilon^2 \lambda_0)^{-1}
\]
We take a smooth extension, which has a singularity at the edge (1.30); the larger domain is shaded in Fig. 5.1.b. More precisely, we use the representation (3.17) near the edge and keep the form of $K_0(s)$, $K_1(s)^{1/2} \cos(\varphi/2)$ unchanged and handle the remainder $\hat{v}_1$ only. In this way the extensions $\hat{v}_1^\pm$ will still satisfy the estimates (3.18).

To avoid superfluous technical details we describe the first case and only comment on the second one at the end.

Let us derive a lower estimate for the $L^2$-norm of the function (5.8) written in the form

$$u_{as}^\varepsilon(x) = \left(1 - \sum_{\pm} \chi_\pm(x_1)\right)U_\varepsilon(x') + X_\varepsilon(x_1)\varepsilon\hat{v}_1(x)$$

$$+ \sum_{\pm} \chi_\pm(x_1)(1 \pm \varepsilon b_0)e^{\mp\mu_\varepsilon}U_\varepsilon(x'),$$

where the formulas (2.12) for $v_0$ and (2.23) for $v_1$ were applied. The first term on the right has compact support and the second one decays exponentially, but, according to (2.4), the decay of the third term is very slow. Thus,

$$\|u_{as}^\varepsilon; L^2(\Omega^\varepsilon_r)\|^2 \geq \|u_{in}^\varepsilon; L^2(\Omega^\varepsilon_r \setminus \Omega^\varepsilon_r(2))\|^2$$

$$\geq C_1 \int_2^\infty e^{-2\mu_0|x_1|}d|x_1| - C_0\varepsilon \geq \frac{C_2}{\varepsilon}, \quad C_p > 0,$$

where $\Omega^\varepsilon_r(2)$ is as in (4.3).

\section{Calculation of the discrepancies.}

Let us compute in the equation (1.15) the discrepancy of the function (5.8), which is written more briefly as follows:

$$u_{as}^\varepsilon = X_\varepsilon u_{in}^\varepsilon + \sum_{\pm} \chi_\pm u_{out,\pm}^\varepsilon - X_\varepsilon \sum_{\pm} \chi_\pm u_{mat,\pm}^\varepsilon.$$
Since $u_{in}^\varepsilon$, $u_{out,\pm}^\varepsilon$, and $u_{mat,\pm}^\varepsilon$ are harmonic, the first two terms on the right vanish. Coefficients of the differential operator $\chi_\pm[\Delta, X_\varepsilon]$ are supported in $\{x \in \Pi_\varepsilon : \pm x_1 - 1/\varepsilon \in [0, 1]\}$, where the difference $u_{in}^\varepsilon - u_{mat,\pm}^\varepsilon = \varepsilon \overline{v}_1$ is exponentially small, see (2.12) and (2.23). Recalling the asymptotic formulas (2.4) and (2.8) and the decomposition (2.10) specified in (2.9), (2.12), (2.29), and (2.25), we conclude that the difference $u_{out,\pm}^\varepsilon - u_{mat,\pm}^\varepsilon$ is of the order $\varepsilon^2$ in the set $\{x \in \Pi_\varepsilon : 1 \leq \pm x_1 \leq 2\}$. In this set the commutator $[\Delta, \chi_\pm]$ is not null, in view of (2.21). Hence,

\begin{equation}
|\Delta u_{as,\varepsilon}^\varepsilon(x)| \leq C\varepsilon^2 e^{-\alpha_0 |x_1|} \quad \text{for some } \alpha_0 > 0.
\end{equation}

On the cylindrical surface $\partial \Pi$ the normal derivative annihilates all three cut-off functions depending on the longitudinal variable only. We thus find that the asymptotic solution (5.8) satisfies the Neumann condition

\begin{equation}
\partial_n u_{as,\varepsilon}^\varepsilon(x) = 0, \quad x \in \Sigma_\varepsilon^r,
\end{equation}

and the discrepancy in the Steklov condition looks as follows:

\begin{equation}
\partial_\lambda u_{as,\varepsilon}^\varepsilon(x) - (\Lambda_\varepsilon - \varepsilon^2 \lambda_0)u_{as,\varepsilon}^\varepsilon(x) = \varepsilon^2 \lambda_0 X_\varepsilon(x_1) \left(u_{in,\varepsilon}^\varepsilon(x) - \sum_{\pm} \chi_\pm(x_1)u_{mat,\pm}^\varepsilon(x)\right)
\end{equation}

in $\Omega_\varepsilon^r$. In this set the exponential decay of the remainder in (2.23) we see that

\begin{equation}
|\partial_\lambda u_{as,\varepsilon}^\varepsilon(x_1, x_2, 0) - \lambda_\varepsilon u_{as,\varepsilon}^\varepsilon(x_1, x_2, 0)| \leq c\varepsilon^2 e^{-\alpha_0 |x_1|}, \quad x \in \Omega_\varepsilon^r.
\end{equation}

We are left with examining the boundary conditions (1.16) on the screen surfaces (1.5). Clearly, $u_{as,\varepsilon}^\varepsilon(x) = U_\varepsilon(x') + \varepsilon v_1(x)$ in a neighbourhood of $\Theta_\varepsilon^c$. We use the representation (2.17) for the normal derivative and the relation (2.19). As a result, we obtain

\begin{equation}
(1 + \varepsilon^2 |\nabla 'h_\pm(x')|^2)^{1/2} \partial_\lambda (U_\varepsilon(x') + \varepsilon v_1(x)) \bigg|_{x_1 = \pm \varepsilon h(x')}
= \varepsilon (\nabla 'h_\pm(x') \cdot \nabla 'U_\varepsilon(x') \mp \partial_1 v_1(\pm \varepsilon h_\pm(x'), x') + \varepsilon \nabla 'h_\pm(x') \cdot \nabla 'v_1(\pm \varepsilon h_\pm(x'), x')
= \pm \varepsilon (\partial_1 v_1(0, x') - \partial_1 v_1(\pm \varepsilon h_\pm(x'), x') + \varepsilon^2 \nabla 'h_\pm(x') \cdot \nabla 'v_1(\pm \varepsilon h_\pm(x'), x')
\end{equation}

Applying the Taylor formula and the estimates

\begin{equation}
|\nabla ^p v(x)| \leq c_p (1 + r^{-p+1/2} + r^{1/2}(L - s)^{1-p}), \quad p = 0, 1, 2,
\end{equation}

which follow for example from the relations (3.17) and (3.18), yield the inequality

\begin{equation}
|\partial_\lambda (U_\varepsilon(x') + \varepsilon v_1(\pm \varepsilon h_\pm(x'), x'))| \leq \varepsilon^2 r^{-1/2}, \quad x \in \theta^r_{\pm, r}.
\end{equation}

### 5.4. Final estimate.

By the definition of the Hilbert space norm and the formulas (4.12), (4.13) we have

\begin{align*}
\|T_{\varepsilon} u_{as,\varepsilon}^\varepsilon - \tau_{as} u_{as,\varepsilon}^\varepsilon : H^\varepsilon\| & = \inf \{ \langle T_{\varepsilon} u_{as,\varepsilon}^\varepsilon, w^\varepsilon \rangle - \tau_{as} \langle u_{as,\varepsilon}^\varepsilon, w^\varepsilon \rangle \} \\
& = \tau_{as} \inf \{ |\lambda_{as}^\varepsilon (u_{as,\varepsilon}^\varepsilon, w^\varepsilon)_{\Gamma^\varepsilon_{\varepsilon}} - \langle \nabla u_{as,\varepsilon}^\varepsilon, \nabla w^\varepsilon \rangle_{\Omega^\varepsilon_{\varepsilon}}| \} \\
& = \tau_{as} \inf \{ |\Delta u_{as,\varepsilon}^\varepsilon, \nabla w^\varepsilon \rangle_{\Omega^\varepsilon_{\varepsilon}} - (\partial_\lambda u_{as,\varepsilon}^\varepsilon - \lambda_{as}^\varepsilon u_{as,\varepsilon}^\varepsilon, w^\varepsilon)_{\Gamma^\varepsilon_{\varepsilon}} - \sum_{\pm} (\partial_\lambda u_{as,\varepsilon}^\varepsilon, w^\varepsilon)_{\omega_{\varepsilon, \varepsilon}}| \}.
\end{align*}
Here, the infimum is calculated over all functions \( v^\varepsilon \in \mathcal{H}^\varepsilon \) such that
\[
\|w^\varepsilon; \mathcal{H}^\varepsilon\| = \|\nabla w^\varepsilon; L^2(\Omega^\varepsilon_r)\| = 1;
\]
according to (4.15) and (3.16), these functions also satisfy
\[
\|w^\varepsilon, L^2(\Omega^\varepsilon_r)\| + \|w^\varepsilon, L^2(\Gamma^\varepsilon_r)\| + \sum_{\pm} \|r^{-1/2}(1 + |\ln r|)^{-1}w^\varepsilon; L^2(\theta^\varepsilon_{\pm,r})\| \leq C. \tag{5.18}
\]

Now the estimates (5.13), (5.15), and (5.17) imply the inequality
\[
\|T^\varepsilon u^\varepsilon_{as} - \tau^\varepsilon_{as} u^\varepsilon_{as}; \mathcal{H}^\varepsilon\| \leq c\varepsilon^2, \tag{5.19}
\]
which together with (5.10) show that the factor in (5.1) does not exceed \( c\varepsilon^{5/2} \), and therefore (5.2) is true. Hence, the operator \( T^\varepsilon \) has an eigenvalue \( \tau^\varepsilon_1 \in [\tau^\varepsilon_{as} - \delta, \tau^\varepsilon_{as} + \delta] \).

Finally, the calculation (5.3) and the formula (5.6) assure the relations (2.1) and
\[
\Delta \tau^\varepsilon_1 = \frac{\varepsilon}{\ln r} \theta^\varepsilon_1 = (\tau^\varepsilon_1)^{-1}
\]
for the eigenvalue \( \lambda^\varepsilon = \lambda^\ast_1 = (\tau^\varepsilon_1)^{-1} \) of the problems (1.15)–(1.18) and (1.8)–(1.10). Theorem 1.1 is proved.

Let us comment on the case \( h_+ < 0 \) depicted in Fig. 5.1.b, and outlined at the end of Section 3.3. The formulas (5.14) and (5.17) remain unchanged. The extension \( v^\varepsilon_+ \) is not harmonic in the thin domain \( \Xi^\varepsilon_+ = \{x : 0 > x_1 > \varepsilon h_+(x'), x' \in \theta_r\} \), and therefore
\[
\Delta v^\varepsilon_+(x) = 0 \quad \text{in } \Pi_{+r} \quad \text{but } \quad \Delta v^\varepsilon_+(x) = \varepsilon \Delta v^\varepsilon_1+(x) \quad \text{in } \Xi^\varepsilon_+. \tag{5.20}
\]

However, according to the relations (3.17), (3.18) and the Taylor formula in the variable \( x_1 \), we have
\[
|\nabla v^\varepsilon_1+(x)| = |\Delta v^\varepsilon_1+(x) - \Delta v^\varepsilon_1+(0, x')| \leq C|x_1|r^{-3/2}(1 + |\ln \varrho|).
\]

Furthermore, a direct consequence of the Newton-Leibnitz formula
\[
\int_{\Xi^\varepsilon_+} |w^\varepsilon(x)|^2 \, dx \leq c\varepsilon \int_{\Omega^\varepsilon_r} (|\nabla w^\varepsilon(x)|^2 + |w^\varepsilon(x)|^2) \, dx \tag{5.21}
\]
shows that
\[
\varepsilon \left| \int_{\Xi^\varepsilon_+} w^\varepsilon(x) \Delta v^\varepsilon_+(x) \, dx \right|^2 \\
\leq c\varepsilon^{1/2} \|w^\varepsilon; \Omega^\varepsilon_r(R)\| \left( \int_{\varepsilon h_+(x')}^0 |x_1|^2 \int_{\theta_r} r^{-3}(1 + |\ln \varrho|)^2 \, d\varrho' \, dx_1 \right)^{1/2} \\
\leq c\varepsilon^3 \left( \int_{\theta_r} h_+(x')^3 r^{-3}(1 + |\ln \varrho|)^2 \, d\varrho' \right)^{1/2} \leq c\varepsilon^3.
\]

Here we used the relation (5.18) for \( w^\varepsilon \) and observed that the last integral converges because the singular factor \( r^{-3} \) is compensated by \( h_+(x')^3 \), owing to the assumption \( 3^\circ \). A similar calculation shows that
\[
\left| \langle \partial_z u^\varepsilon_{as} - \lambda^\varepsilon_{as} u^\varepsilon_{as}, w^\varepsilon \rangle_{\Gamma^\varepsilon_r} \right| \leq c\varepsilon^2, \tag{5.22}
\]
and hence our previous conclusion (5.19) as well as Theorem 1.1, (2) are still valid. It should be mentioned that instead of (5.21) the derivation of (5.22) can be based
on the estimate
\[
\int_0^l \int_0^{\varepsilon h_+(x_2,0)} |w^\varepsilon(x_1, x_2, 0)|^2 dx_1 dx_2 \leq c\varepsilon(1 + |\ln \varepsilon|)^2 \|w^\varepsilon; H^1(\Omega^\varepsilon(R))\|^2
\]
which follows from a Hardy-type trace inequality analogous to (3.16).

Theorem 1.1 can be proven in the same way but the extension of the asymptotic ansätze in Section 3.1 requires much more cumbersome but still routine calculations, which we omit here for brevity.

6.1. Discussion. In the previous sections we have studied the position of the lowest embedded eigenvalue \(\lambda^\varepsilon\) of the linear water-wave problem (1.8)–(1.10) in a straight channel containing a thin screen. The thickness of the screen has been considered as a small parameter of order \(\varepsilon > 0\), and we have assumed that the geometry of the problem is symmetric along the longitudinal mid-plane. Our results in Theorems 1.1 and 3.1 show how the integral characteristic \(I(h), (2.28)\), and the lowest eigenvalue \(\Lambda^\dagger\) of the associated water-wave problem with artificial boundary condition (1.15)–(1.20) play crucial roles in the determination of the asymptotic position of \(\lambda^\varepsilon\).

Our formal analysis, with small modifications, can be applied to asymmetric screens, but this topic will be postponed to a planned forthcoming paper, since the justification scheme would require essential changes. Asymmetry of the screen may lead to complex resonances or unstable embedded eigenvalues. (Notice that the eigenvalue found above belongs to the discrete spectrum of the problem (1.15)–(1.18) with the artificial Dirichlet condition, and it is therefore stable for small, symmetric perturbations of the profile functions \(h^\pm\) in (1.3).)

As for possible other embedded eigenvalues, we have not made any effort to analyse for example eigenvalues above the threshold \(\Lambda^\dagger\). Embedded eigenvalues are in general unstable by nature. This has to be taken into account in the asymptotic analysis of eigenvalues larger than \(\Lambda^\dagger\), and the investigation of such eigenvalues should be based on the fine-tuning procedure of [21, 22] mentioned already in Section 1.2; this also allows one to stabilise the eigenvalues to stay in the continuous spectrum. Since the present approach does not include a stabilisation procedure, we refrain from the computing of numerical examples, which would require ideas beyond the scope of the paper.

Let us make some further comments on the relation with the results of [18]. The sufficient condition for the existence of a trapped mode in [18] was formulated as the inequality
\[
(6.1) \quad \int_{\Theta^\varepsilon} |\nabla U_\dagger(\mathbf{x}')|^2 d\mathbf{x} - \Lambda^\dagger \int_{\Gamma^\dagger \Theta^\varepsilon} |U_\dagger(\mathbf{x}')|^2 dx_1 dx_2 \geq 0.
\]
This turns into the inequality \(\varepsilon I(h) \geq 0\), (2.28), by using (1.3) and an integration with respect to \(x_1\). If \(3^\dagger\) is in addition assumed, Theorems 1.1 and 3.1 yield a positive number \(\varepsilon_0(\theta, h^\pm)\) depending on the screen profiles such that if \(0 < \varepsilon < \varepsilon_0(\theta, h^\pm)\), then (6.1) is also a necessary condition for a unique trapped mode, thus improving the results of [18]. For large \(\varepsilon\) this necessity and uniqueness may of course be lost.
2. Particular screens. We now discuss two examples which show that our assumption \( 3^o \) means an essential simplification of calculations, since removing it would make the asymptotic analysis in Section 2.3 not valid. As was mentioned in Section 1.3 and follows from the sufficient condition (6.1), any submerged screen \( \Theta^\varepsilon \subset \Pi \) traps a surface wave, with the exception of the case of a vertical planar screen. Let us discuss the boundary layer phenomenon for the flattened ellipsoid

\[ \Theta^\varepsilon = \{ x : R^{-2}(x_2^2 + (x_3 - z_0)^2) + \varepsilon^{-2}x_1^2 \leq 1 \} \]

(cf. \cite{30} for the much more simple two dimensional case) and for the penny-shaped obstacle

\[ \Theta^\varepsilon = \{ x : x_2^2 + (x_3 - z_0)^2 \leq R^2, \, |x_1| < \varepsilon \}; \]

Both screens (6.2) and (6.3) are submerged and do not touch the wetted surface \( \Sigma \) of the channel \( \Pi \), see Fig. 6.1.a,c.

The ellipsoid (6.2) is given by the formula (1.3), where \( \theta \) is a disc of radius \( R \) and

\[ h_{\pm}(x') = \sqrt{1 - R^{-2}(x_2^2 + (x_3 - z_0)^2)} = \sqrt{r}(R^{-1} + O(r)) \]

Since \( h_{\pm} \) vanish on the circle \( \psi = \partial \theta \), all calculations of Section 2 can be repeated word-to-word to derive the asymptotic formula (2.1) for the single eigenvalue \( \lambda^\varepsilon \in (0, \Lambda^\dagger) \) of (1.8)–(1.10). However, the decay rate \( O(r^{1/2}) \) in (6.4) is not enough to compensate the growth \( O(r^{-3/2}) \) of the second order derivatives of \( v \), cf. the right hand side of (3.10). As a result, higher order terms cannot be found using the above presented asymptotic method. Indeed, it was shown in \cite{9}, see also \cite{15}, that the boundary layer phenomenon occurs in the vicinity of the edge \( \Psi = \{ x : x_1 = 0, \, \rho := (x_2^2 + (x_2 - z_0)^2)^{1/2} = R \} \). Namely, dilating coordinates as

\[ (x_1, \rho) \mapsto \xi = (\xi_1, \xi_2) = (\varepsilon^{-2}x_1, \varepsilon^{-2}(\rho - R)), \]
using the arc length \( s \in [0, 2\pi R] \) on \( \Psi \) and setting \( \varepsilon = 0 \) lead to a Neumann problem for the two-dimensional Laplacian \( \Delta_\xi \) in the plane \( \mathbb{R}^2 \) with parabolic notch
\[
P = \{ \xi : \xi_2 < 0, \ |\xi_1| \leq (2|\xi_2|/R)^{1/2} \},
\]
see Fig. 6.1.b. Detailed analysis of the boundary can be found in [9] and [15, Ch. 5].

For the penny-shaped screen (6.2) we have \( h_\pm(x') = 1 \), and we come across a notable inconsistency in the previous calculations: the right hand side of (2.19) vanishes and the problem (2.13)–(2.16), (2.19) thus turns homogeneous, but according to (2.28), the coefficient \( b_1 \) in (2.23) takes the form (2.25) with \( I(h) = 2\|\nabla'U_1; L^2(\theta_r)\|_2^2 \).

This contradiction is of course caused by the boundary layer effect. Using the coordinate dilation
\[
(x_1, \rho) \mapsto \xi = (\varepsilon^{-1} x_1, \varepsilon^{-1}(\rho - R)),
\]
the effect is described by the solutions of the Neumann problem for \( \Delta_\xi \) in the plane without the semi-strip
\[
\mathbb{S} = \{ \xi : \xi_2 \leq 0, \ |\xi_1| < 1 \},
\]
see Fig. 6.1.d. Indeed, the function \( v_0(x) = U_1(x') \) has the discrepancy \( G(s) = \partial_r U_1(x')|_{r = R} \) in the Neumann condition on the lateral side of the circular cylinder (6.3). Therefore the main asymptotic term \( \varepsilon W(\xi, s) \) of the boundary layer is to be chosen as a solution of the following problem with parameter \( s \):
\[
-\Delta_\xi W(\xi, s) = 0, \ \xi \in \mathbb{S},
\]
\[
\mp \partial_1 W(\pm 1, \xi_2, s) = 0, \ \xi_2 < 0,
\]
\[
-\partial_2 W(\xi_1, 0, s) = G(s), \ \xi_1 \in (-1, 1).
\]

Unfortunately, this problem has no solutions which decay at infinity. This is why we employ the traditional method of matched asymptotic expansions, see [29, 9] and change the essence of \( \varepsilon W(\xi, s) \): it is regarded as a term in the inner expansion near the edge of the screen, and it is fixed as a solution of the problem (6.5) with logarithmic growth at infinity,
\[
W(\xi, s) = -\pi^{-1}G(s) \ln |\xi| + o(1), \ |\xi| \to +\infty.
\]

Now, (2.11) is regarded as the outer expansion in a neighbourhood of \( \Theta^\varepsilon \), and its term \( \varepsilon v_1(x) \) must be subject to the asymptotic condition
\[
v_1(x) = -\pi^{-1}G(s) \ln r + O(1), \ r \to +0.
\]

This term thus becomes a nontrivial singular solution of the homogeneous problem (1.25)–(1.28). This explains why our calculations in Section 2.3 do not work for the penny-shaped screen. In other words, the assumption \( 3^\circ \) simplifies calculations and removing it requires a different asymptotic analysis.

6.3. **Surface-piercing screens.** If the screen thickness function \( h \) does not vanish at the endpoints of the line segment \( \phi = \partial \theta \cap \gamma \), then, yet another boundary layer must be taken into account, in addition to those discussed in Section 6.2. This amounts to solving a Neumann problem in the lower half-space with the infinite slit of width \( h^0 = h^0_+ + h^0_- > 0 \),
\[
\{ \eta = (\eta_1, \eta_2, \eta_3) : \eta_3 < 0, \ \eta_2 < 0, \ \eta_1 \in [-h^0_-, h^0_+] \}.
\]
The authors do not know published results in this direction. Another open question is related to the situation, when $h$ is null on $\psi \setminus \tau$ but positive on the arc $\tau = \{ s : s \in (-t, t) \}$ of length $2t > 0$.

In addition to the assumption $3^\circ$ we have required in Section 1.1 that the angle $\alpha$ between $\psi$ and $\gamma$ is right. We used this restriction in Section 3.3, since we needed the extension trick to study the singularities of $v_2$. However, this assumption may be weakened: it was shown in [17] that the exponent $\beta$ in the ”worst” power-law solution (3.13) is a function, which decreases monotonely from 1 to 0, when the variable is the angle $\alpha$ measured from the side of $\theta$. Thus, our calculations remain valid at least for acute angles.
