First report on egg-parasitoids of the Asian planthopper

*Ricania speculum*

Abstract

The first findings of egg-parasitoids of the invasive planthopper *Ricania speculum* (Walker) (Hemiptera Ricianiae) are presented. *Aprostocetus* (Osttetristachus crino* (Walker) (Hymenoptera Eulophidae), a native species until now only associated with Oeanc-thus spp. (Orthoptera Oecanthidae) eggs, was the most common. *Chaetostricha similis* (Silvestri) (Hymenoptera Trichogrammati-dae) and *Polynema* sp. (Hymenoptera Mymaridae), which also emerged from *R. speculum* egg clusters, should be confirmed as parasitoids of this planthopper.

Key words: *Aprostocetus crino*, *Chaetostricha similis*, *Polynema* sp., native species, Italy.

Introduction

The first European records of the Asian planthopper *Ricania speculum* (Walker) were reported by Mazza et al. (2014) in the province of Genoa and by Rossi and Lucchi (2015) in the province of La Spezia. The other congeneric species occurring in Europe are *Ricania hedeborgi* Stal and *Ricania japonica* Melichar, invasive in Greece and Ukraine, respectively (Gjnov, 2011; Gjnov and Shishiniova, 2014; Gnezdilov, 1999; Hoch, 2002; Holzinger et al., 2003; Nast, 1987). *Ricania simulans* (Walker) has been recently recorded only in Turkey (Ak et al., 2015). The family Ricianiae (Hemiptera Fulgorormorpha) includes species distributed mainly in Asia, Australia, and tropical Africa.

*R. speculum* has been recorded in China, Indonesia, Japan, Korea, the Philippines, Taiwan, and Vietnam (Bourgojn, 2016), and is broadly polyphagous (Mazza et al., 2014; Rossi and Lucchi, 2015, Rossi et al., 2015). Females insert eggs into the woody twigs of many host plants on which nymphs feed and develop (Rossi and Lucchi, 2015; Rossi et al., 2015). Egg, egg-burster, and male and female genitalia morphologies were recently described and illustrated (Lucchi and Rossi, 2016; Rossi and Lucchi, 2015; Wilson et al., 2016).

Few natural enemies of Ricianiae have been recorded to date. Among the known parasitoids is listed Centro-dora scolypopae Valentine (Hymenoptera Aphelinidae), which parasitizes the eggs of Scolytopa australis (Walker) (Valentine, 1966). With regard to the genus *Ricania*, only two Dryinidae (Hymenoptera Chrysi-doidae) and one Salticidae (Araneae) of the genus Phidippus sp. are recorded as natural enemies (Guglielmino et al., 2013; Swaminathan and Ananthakrishnan, 1982). *Tetrastichus* sp. (Hymenoptera Eulophidae) and *Protourcerus fulgoridis* Ferriere (Hymenoptera Encyti-dae) have been reported as parasitoids of *Ricania fenestrata* (F.) (Noyes, 2017), but in the original paper the records were associated with *Eurybrachys tomentosa* F. (Hemiptera Eurybrachidae) (Swaminathan and Ananthakrishnan, 1982).

Based on observations from an eight-month period between 2014 and 2015, we consider *R. speculum* an important threat to European crops. Taking into consideration the current diffusion and the first unofficial record of this species (entomological forum Natura Mediterraneo: http://www.naturamediterraneo.com/), we presume that the accidental introduction of *R. speculum* can be dated to at least six-seven years ago. As a consequence of the lack of natural enemy regulation in new areas (Keane and Crawley, 2002) this planthopper could become invasive.

Here, we report the first record of some native parasites of *R. speculum* eggs collected in Liguria (Northern Italy) in the spring of 2016.

Materials and methods

*R. speculum* egg clusters were collected in some localities of Genoa and La Spezia provinces (Liguria, Italy), in March-April 2016 (table 1).

The small twigs and stalks containing the eggs were maintained in cylindrical glass vials (length 100 mm, diameter 10 mm), under laboratory conditions (24 ± 1 °C, 60 ± 10% RH, and L:D 16:8), in order to obtain possible parasitoids. All emerging adult parasitoids were kept with the numerical code given to the preserved egg and host plant data. Emerging parasitoids were individually preserved in 70% ethanol. Some specimens used for taxonomic identification were mounted on slides using balsam-phenol as a permanent medium; others were mounted on cards.

Results and discussion

In April 2016, 9 adult parasitoids emerged from egg clusters: 4♀ and 3♂ of an *Aprostocetus* sp., 1♀ of *Polynema* sp. and 1♀ of a *Chaetostricha* sp. They were identified by G. Viggiani and S. Laudonia and reported as follows.

(In colour at www.bulletinofinsectology.org)
Aprostocetus (Ootetrastichus) crino (Walker) (Hymenoptera Eulophidae) (figure 1), which is widespread in Europe and is also recorded in China and North America, is an egg parasitoid of Oecanthus spp. (Orthoptera Oecanthidae). Graham (1987) redescribed this species in detail, as it exhibits variability in colour and morphological characteristics. Our specimens were compared with the type material of Tetrastichus (Geniocerus) dispar Silvestri a prior synonym of A. crino (Silvestri, 1920). While this species may include variation, additional limiting parameters beyond those given by Graham (1987) have been recorded, namely for the male antennae and the length/width ratios of the funicular segments (up to 1.2 times as long as wide) and the club (up to 2.6-3.0 times long as wide). Our specimens emerged from R. speculum eggs laid on Clematis vitalba L. and Eupatorium cannabinum L.

Regarding the hosts of A. crino, Graham (1987) noted, “none of these hosts occurs in northern Europe so that crino must have other hosts in that region”. Our record supports Graham’s view. This species has strangely been reported as a parasitoid of a prepupa of Yponomeuta padella (L.) (Lepidoptera Yponomeutidae) (Noyes, 2017; Yegorenkova et al., 2007).

Chaetostricha similis (Silvestri) (Hymenoptera Trichogrammatidae) (figure 2a). This species is known only from the original description in Campania, Italy (Silvestri, 1918). Species of the genus Chaetostricha are recorded as egg parasitoids of Membraucidae and Miridae (Pinto, 2006).

Polynema sp. (Hymenoptera Mymaridae) (figure 2b). The present taxonomy within this genus, particularly for the Paleartic species, suggests avoiding uncertain species identification.

C. similis and Polynema sp., which also emerged from R. speculum egg clusters, both with only one specimen, should be confirmed as new associate with this planthopper.

The first findings of egg-parasitoids of R. speculum support the hypothesis of a shift of some native species to a new host, as in the Ecological Sorting Hypothesis (Weiher and Keddy, 1999). Research in progress will clarify the population dynamics of Ricania and the relationship among the entomophagous Ricania species.

Acknowledgements

Many thanks are due to the student Greta Masserano for taking care of the egg clusters in the Pisa University laboratories.
