## A STUDY ON PYTHAGOREAN TRIPLES

 <br> A. Dinesh Kumar* \& M. Vasuki** <br> * Head \& Assistant Professor, Department of Science and Humanities, Dhanalakshmi Srinivasan Engineering College, Perambalur, Tamilnadu <br> ** Assistant Professor, Department of Mathematics, Srinivasan College of Arts and Science, Perambalur, Tamilnadu <br> Cite This Article: A. Dinesh Kumar \& M. Vasuki, "A Study on Pythagorean Triples", International Journal of} Interdisciplinary Research in Arts and Humanities, Page Number 14-21, Volume 1, Issue 1, 2016.

## Introduction:

The Pythagorean numbers play a significant role in the theory of higher arithmetic as they come in the majority of indeterminate problem. For the discovery of the law of the three squares (Pythagorean equation), really, one should be indebted to the Pythagorean who were the first Greeks with great intellectual perception. One may notice to his surprise that the Egyptians, the Chinese, the Babylonians and the Indians knew some knowledge of the property of right angled Pythagorean triangles or Pythagorean numbers .Since there is a $1-1$ correspondence between Pythagorean numbers and Pythagorean triangles, we shall use them interchangeably. The only geometrical theorem with which the ancient Chinese were acquainted is that the area of the square described on the hypotenuse of a right angled triangle is equal to the sum of the areas of the squares described on the sides. A Pythagorean triangle is a right triangle whose sides are integral lengths.
Pythagorean Triples: Let $(x, y, z)$ denote 3-tuple where $x, y$ and $z$ are integer. ( $x, y, z$ ) is a Pythagorean triple $\equiv(1)$ $x, y$ and $z$ are positive. (2) $x^{2}+y^{2}=z^{2}$
Primitive Pythagorean Triple: Let $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ denote a 3 -tuple where $\mathrm{x}, \mathrm{y}, \mathrm{z}$ and z are integers. $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a primitive Pythagorean triple $\Xi(1)(x, y, z)$ is a Pythagorean triple. (2) $\operatorname{GCD}(x, y, z)=1$.

## Theorem 1:

$\operatorname{If}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a Pythagorean triple such that $\mathrm{GCD}(\mathrm{x}, \mathrm{y})=1$ then $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a primitive Pythagorean triple.
Proof:
Without loss of generality,let us assume that, There exists a prime p such that $\mathrm{p} / \mathrm{x}$ and $\mathrm{p} / \mathrm{z}$ Then $\mathrm{p} /\left(\mathrm{z}^{2}-\mathrm{x}^{2)}=\mathrm{y}^{2}\right.$ $\Rightarrow \mathrm{p} / \mathrm{y}^{2}$. Hence $\mathrm{p} / \mathrm{y}$, Where contradicts $\mathrm{GCD}(\mathrm{x}, \mathrm{y})=1 . \therefore(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a primitive Pythagorean triple.

## Theorem 2:

$\operatorname{If}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a Pythagorean triple then there exists a primitive Pythagorean triple $(\mathrm{a}, \mathrm{b}, \mathrm{c})$ and there exists an integer $k \geq 1$ such that $(x, y, z)=(k a, k b, k c)$

## Proof:

| Let $\mathrm{k}=\mathrm{GCD}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ and let $\mathrm{a}=\mathrm{x} / \mathrm{k}$ | $\rightarrow(1)$ |
| :--- | :--- |
| $\mathrm{b}=\mathrm{y} / \mathrm{k}$ | $\rightarrow(2)$ |
| and | $\mathrm{c}=\mathrm{z} / \mathrm{k}$ |

Then GCD $(a, b, c)=1$. Next T.P.T $(a, b, c)$ is a Pythagorean triple. Square (1) \& (2) and add $a^{2}+b^{2}=x^{2} / k^{2}+y^{2} / k^{2}$

$$
\begin{gathered}
=\frac{x^{2}+y^{2}}{k^{2}} \\
=z^{2} / k^{2}\left(\underset{x}{ } x^{2}+y^{2}=z^{2}\right) \\
a^{2}+b^{2}=c^{2}(\text { from }(3))
\end{gathered}
$$

$\therefore(\mathrm{a}, \mathrm{b}, \mathrm{c})$ is a Pythagorean triple. Thus $(\mathrm{a}, \mathrm{b}, \mathrm{c})$ is a primitive Pythagorean triple.

## Theorem 3:

$\operatorname{If}(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is a primitive Pythagorean triple then exactly one of x and y is even and z must be odd.
Proof:
$x$ and $y$ cannot both be even. Since $G C D(x, y)=1$. Suppose that $x$ and $y$ are both odd. where $x=2 j+1\}$ and $\mathrm{y}=2 \mathrm{k}+1 \rightarrow$ (4).
Then, $x^{2}+y^{2}=z^{2}$. sub (2.4) in above equation, we get, $(2 \mathrm{j}+1)^{2}+(2 \mathrm{k}+1)^{2}=\mathrm{z}^{2}$

$$
\begin{equation*}
\left(4 j^{2}+4 j+1\right)+\left(4 k^{2}+4 \mathrm{k}+1\right)=\mathrm{z}^{2} \tag{5}
\end{equation*}
$$

$$
4\left(\mathrm{j}^{2}+\mathrm{j}+\mathrm{k}^{2}+\mathrm{k}\right)+2=\mathrm{z}^{2}
$$

Equation (5) implies $\mathrm{z}^{2}$ is even. $\therefore \mathrm{z}$ must be even. Assume that $\mathrm{z}=2 \mathrm{~m}$ sub in (5)

$$
4\left(\mathrm{j}^{2}+\mathrm{j}+\mathrm{k}^{2}+\mathrm{k}\right)+2=4 \mathrm{~m}^{2}
$$

Now 4 divides the R.H.S of this equation, but 4 does not divide the L.H.S. Which is contradiction to our assumption? One of these values must be even, and since $\operatorname{GCD}(x, y)=1$, the other value must be odd. Thus exactly one of x and y is even, z must be odd.

## Corollary 1:

Every Pythagorean triple consists of 2 odd integers and 1 even integers or else consists of 3 even integers. Proof:

Let $x$ and $y$ are both odd. where $x=2 j+1$ and $y=2 k+1$
Then, $x^{2}+y^{2}=z^{2}$, Substitution of (6) in above equations implies $(2 j+1)^{2}+(2 k+1)^{2}=z^{2}$

$$
\left(4 \mathrm{j}^{2}+4 \mathrm{j}+1\right)+\left(4 \mathrm{k}^{2}+4 \mathrm{k}+1\right)=\mathrm{z}^{2}
$$

$$
4\left(\mathrm{j}^{2}+\mathrm{j}+\mathrm{k}^{2}+\mathrm{k}\right)+2=\mathrm{z}^{2}
$$

This last equation implies $z^{2}$ is even. So $z$ must be even. $\therefore$ Every Pythagorean triple consists of 2 odd integers and 1 even integer.
Convention:
If ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ) denotes a Pythagorean triple ,then x will always denote an even integer.

## Theorem 5:

 If ( $x, y, z$ ) is a primitive Pythagorean triple then there exists an integer $k$ such that $x=4 k$.Proof:
By theorem 3 and convention, Let $x=2 r, y=2, s+1$ and $z=2 t+1$ Then, $x^{2}=z^{2}-y^{2}$

$$
\begin{gathered}
(2 \mathrm{r})^{2}=(2 \mathrm{t}+1)^{2}-(2 \mathrm{~s}+1)^{2} \\
4 \mathrm{r}^{2}=4 \mathrm{t}^{2}+4 \mathrm{t}+1-\left(4 \mathrm{~s}^{2}+4 \mathrm{~s}+1\right) \\
4 \mathrm{r}^{2}=4\left(\mathrm{t}^{2}+\mathrm{t}-\mathrm{s}^{2}-\mathrm{s}\right) \\
\mathrm{r}^{2}=\mathrm{t}(\mathrm{t}+1)-\mathrm{s}(\mathrm{~s}+1)
\end{gathered}
$$

$\therefore \mathrm{r}^{2}$ is the difference between two even integers. Hence $\mathrm{r}^{2}$ must be even. $\therefore \mathrm{r}$ must be even. Assume $\mathrm{r}-2 \mathrm{k}$ Then $\mathrm{x}=2 \mathrm{r}=2.2 \mathrm{k}=4 \mathrm{k}$
Theorem 6: If $0<n<m$ then $\left(2 m n, m 2-\mathrm{n}^{2}, \mathrm{~m}^{2}+\mathrm{n}^{2}\right)$ is a Pythagorean triple.

## Proof:

Take $\mathrm{x}=2 \mathrm{mn}, \mathrm{y}=\mathrm{m}^{2}-\mathrm{n}^{2}$ and $\mathrm{z}=\mathrm{m}^{2}+\mathrm{n}^{2}$
T.P.T: $(2 m n)^{2}+\left(m^{2}-n^{2}\right)^{2}=\left(m^{2}+n^{2}\right)^{2}$ Let $x^{2}+y^{2}=z^{2}$, Substitute the value of $x$ and $y$ in above equation

$$
(2 m n)^{2}+\left(m^{2}-n^{2}\right)^{2}=4 m^{2} n^{2}+m^{4}-2 \mathrm{mn}^{2}+n^{4}=m^{4}+2 m^{2} n^{2}+n^{4}=\left(m^{2}+n^{2}\right)^{2}
$$

( $2 \mathrm{mn}, \mathrm{m}^{2}-\mathrm{n}^{2}, \mathrm{~m}^{2}+\mathrm{n}^{2}$ ) is a Pythagorean triple

## Corollary 2:

If $0<n<m$ and $\operatorname{GCD}\left(2 m n, m^{2}-n^{2}\right)=1$ then $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple.

## Proof:

By the Theorem 6, $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a Pythagorean triple. By Theorem 1, If $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a Pythagorean triple such that GCD $\left(2 m n, m^{2}-n^{2}\right)=1$. Then $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple.

## Theorem 7:

If ( $x, y, z$ ) is a primitive Pythagorean triple then there exists integers $m$ and $n$ such that $x=2 m n, y=m^{2}$ $\mathrm{n}^{2}$, and $\mathrm{z}=\mathrm{m} 2+\mathrm{n}^{2}$
Proof:

Claim: $(\mathrm{t}+\mathrm{s}+1)$ and $(\mathrm{t}-\mathrm{s})$ have no common factor. For if there exists an integer $\mathrm{r}>1$ such that

$$
(\mathrm{t}+\mathrm{s}+1)=\mathrm{r} . \mathrm{p} \text { and }(\mathrm{t}-\mathrm{s})=\mathrm{r} \cdot \mathrm{q}
$$

Then $r(p-q)=r p-r q=t+s+1-t+s=2 s+1=y$

$$
r(p+q)=r p+r q=t+s+1+t-s=2 t+1=z
$$

Which shows is a common factor of $x$ and $z$, an impossibility. Since ( $t+s+1$ ) and ( $t-s$ ) have no common factor.
Yet their product is a perfect square, each must be a perfect square.
Let $\mathrm{m}=\sqrt{t+s+1}$ and $\mathrm{n}=\sqrt{t-s}$ Then $\mathrm{m}^{2}+\mathrm{n}^{2}=(\mathrm{t}+\mathrm{s}+1)+(\mathrm{t}-\mathrm{s})=2 \mathrm{t}+1=\mathrm{z}$

$$
\begin{aligned}
\mathrm{m}^{2}-\mathrm{n}^{2} & =\mathrm{t}+\mathrm{s}+1-\mathrm{t}+\mathrm{s}=2 \mathrm{~s}+1=\mathrm{y} \\
2 \mathrm{mn} & =2 \sqrt{t+s+1} \sqrt{t-s}=2(\mathrm{t}+\mathrm{s}+1) \quad(\mathrm{t}-\mathrm{s}) 1 / 2=2[\mathrm{k}] 1 / 2 \quad \text { (by } 7) \\
& =2 \mathrm{k}=\mathrm{x} \\
\mathrm{x} & =2 \mathrm{mn} . \mathrm{y}=\quad \mathrm{m}^{2}-\mathrm{n}^{2} \text { and } \mathrm{z}=\mathrm{m}^{2}+\mathrm{n}^{2}
\end{aligned}
$$

## Thus Theorem 8:

If ( $x, y, z$ ) is a Pythagorean triple, then there exists integers $k, m$ and $n$ such that $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple. Moreover, $(x, y, z)=\left[k(2 m n), k\left(m^{2}-n^{2}, k\left(m^{2}+n^{2}\right)\right]\right.$

## Proof:

T.P.T: $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple. Let $k=\operatorname{GCD}(x, y, z)$

Let

$$
\begin{array}{rlr}
2 \mathrm{mn}=\mathrm{x} / \mathrm{k} & & \rightarrow(8) \\
\mathrm{m}^{2}-\mathrm{n}^{2}=\mathrm{y} / \mathrm{k} & & \rightarrow(9) \\
\text { and } \quad \mathrm{m}^{2}+\mathrm{n}^{2}=\mathrm{z} / \mathrm{k} & & \rightarrow(10)
\end{array}
$$

Then GCD $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)=1$. Next T.P.T $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple.

$$
\begin{aligned}
& \text { By theorem } 3 \text { and convention, Let } x=2 k, y=2 s+1 \text { and } z=2 t+1 \\
& x^{2}=z^{2}-y^{2} \\
& 4 k^{2}=(z+y) .(z-y) \\
& \begin{aligned}
\mathrm{K}^{2}=z+\frac{z+y}{2} \cdot \frac{z-y}{2}=\frac{(2 t+1)+(2 s+1)}{2} \cdot & \cdot \frac{(2 t+1)-(2 s+1)}{2}=\frac{2 t+2 s+2}{2} \cdot \\
= & (\mathrm{t}+\mathrm{s}+1) .(\mathrm{t}-\mathrm{s})
\end{aligned}
\end{aligned}
$$

Squaring and adding $x$ (8) and (9).

$$
4 \mathrm{~m}^{2} \mathrm{n}^{2}+\left(\mathrm{m}^{2}-\mathrm{n}^{2}\right)^{2}=\frac{x^{2}}{k^{2}}+\frac{y^{2}}{k^{2}}=\frac{x^{2}+y^{2}}{k^{2}}=\frac{z^{2}}{k^{2}}=\left(\mathrm{m}^{2}+\mathrm{n}^{2}\right)^{2}
$$

$\therefore\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a Pythagorean triple. Thus $\left(2 m n, m^{2}-n^{2}, m^{2}+n^{2}\right)$ is a primitive Pythagorean triple.
Let $\quad \mathrm{x}=\mathrm{k}(2 \mathrm{k}), \mathrm{y}=\mathrm{k}(2 \mathrm{~s}+1)$ and $\mathrm{z}=\mathrm{k}(2 \mathrm{t}+1)$
T.P.T: $(x, y, z)=\left[k(2 m n), k\left(m^{2}-n^{2}, m^{2}+n^{2}\right)\right]$

$$
\begin{aligned}
& X^{2}=z^{2}-y^{2} \\
& 4 k^{4}=(z+y) .(z-y) \\
& k^{4}=\frac{z+y}{2} \cdot \frac{z-y}{2}=\frac{k(2 t+1)+k(2 s+1)}{2} \cdot \frac{k(2 t+1)-k(2 s+1)}{2} \\
& \begin{array}{c}
=\frac{2 k t+k+2 k s+k}{2} \cdot \frac{2 k t+1-2 k s-1}{2}=\frac{2 k(t+s)+2 k}{2} \cdot \frac{2 k(t-s)}{2} \\
\mathrm{k} 4=\mathrm{k}(\mathrm{t}+\mathrm{s}+1) \cdot \mathrm{k}(\mathrm{t}-\mathrm{s})
\end{array}
\end{aligned}
$$

Claim: $k(t+s+1)$ and $k(t-s)$ have no common factor. For if there exists an integer $r>1$ such that

$$
\mathrm{k}(\mathrm{t}+\mathrm{s}+1)=\mathrm{r} . \mathrm{p} \text { and } \mathrm{k}(\mathrm{t}-\mathrm{s})=\mathrm{r} . \mathrm{q}
$$

Then $r .(p-q)=r . p-r . q=k(t+s+1)-k(t-s)=t k+k s+k-k t+k s=k(2 s+1)=y$ $r .(p+q)=r . p+r . q=k t+k s+k+k t-k s=k(2 t+1)=z$
Which shows $r$ is a common factor of $y$ and $z$ an impossibility. Since $k(t+s+1)$ and $k(t-s)$ have no common factor Yet their product is a perfect square ,each must be a perfect square.
Let $\mathrm{m}_{\sqrt{k}}=\sqrt{k}(\mathrm{t}+\mathrm{s}+1)$ and $\mathrm{n}_{\sqrt{k}}=\sqrt{k}(\mathrm{t}-\mathrm{s})$ Then $\mathrm{k}\left[\mathrm{m}^{2}+\mathrm{n}^{2}\right]=\mathrm{kt}+\mathrm{ks}+\mathrm{k}+\mathrm{kt}-\mathrm{ks}=\mathrm{k}(2 \mathrm{t}+1)=\mathrm{z}$

$$
\begin{aligned}
& \mathrm{k}\left[\mathrm{~m}^{2}-\mathrm{n}^{2}\right]=\mathrm{kt}+\mathrm{ks}+\mathrm{k}-\mathrm{kt}+\mathrm{sks}=\mathrm{k}(2 \mathrm{~s}+1)=\mathrm{y} \\
& \mathrm{k}[2 \mathrm{mn}]=2[\mathrm{k}(\mathrm{t}+\mathrm{s}+1) \mathrm{k}(\mathrm{t}-\mathrm{s})] 1 / 2=2\left[\mathrm{k}^{4}\right] 1 / 2=2 \mathrm{k}^{2}=\mathrm{x} \\
& \therefore(\mathrm{x}, \mathrm{y}, \mathrm{z})=\left[\mathrm{k}(2 \mathrm{mn}), \mathrm{k}\left(\mathrm{~m}^{2}-\mathrm{n}^{2}\right), \mathrm{k}\left(\mathrm{~m}^{2}+\mathrm{n}^{2}\right)\right]
\end{aligned}
$$

## Sums of Squares:

A Pythagorean triple ( $x, y, z$ ) is a triple of positive integers satisfying $x^{2}+y^{2}=z^{2}$. If $g=\operatorname{gcd}(x, y, z)$ then $(\mathrm{x} / \mathrm{g}, \mathrm{y} / \mathrm{g}, \mathrm{z} / \mathrm{g})$ is also a Pythagorean triple. It follows that if $\mathrm{g}>1,(\mathrm{x}, \mathrm{y}, \mathrm{z})$ can be obtained from the "smaller" Pythagorean triple ( $\mathrm{x} / \mathrm{g}, \mathrm{y} / \mathrm{g}, \mathrm{z} / \mathrm{g}$ ) by multiplying each entry by g . It is natural then to focus on Pythagorean triples $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ with $\operatorname{gcd}(\mathrm{x}, \mathrm{y}, \mathrm{z})=1$ these are called primitive Pythagorean triples.

## Theorem 9:

Let $(x, y, z)$ be a primitive Pythagorean triple. Then $\operatorname{gcd}(x, y)=\operatorname{gcd}(x, z)=\operatorname{gcd}(y, z)=1$.

## Proof:

T.P.T: $\operatorname{gcd}(x, y)=1$, suppose $\operatorname{gcd}(x, y)>1$ Then there is a prime $p$ with $p / x$ and $p / y$. Then $z^{2}=x^{2}+y^{2} \equiv$ $0(\bmod p)$, As $p / z^{2}$ then $p / z$
$\therefore \mathrm{p} / \mathrm{gcd}(\mathrm{x}, \mathrm{y}, \mathrm{z})$, Which is a contradicting $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ being a primitive Pythagorean triple. Thus $\mathrm{gcd}(\mathrm{x}, \mathrm{y})=1$
T.P.T: $\operatorname{gcd}(x, z)=1$, Suppose that $\operatorname{gcd}(x, z)>1$, Then there is a prime $p$ with $p / x$ and $p / z$. Then $y^{2}=z^{2}-x^{2}=0(\bmod p)$ As $\mathrm{p} / \mathrm{y}^{2}$ then $\mathrm{p} / \mathrm{y}, \therefore \mathrm{p} / \operatorname{gcd}(\mathrm{x}, \mathrm{y}, \mathrm{z})$, which is a contradicting $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ being a primitive Pythagorean triple. Thus $\operatorname{gcd}(x, z)=1$.
T.P.T: $\operatorname{gcd}(y, z)=1$, Suppose that $\operatorname{gcd}(y, z)>1$, Then there is a prime $p$ with $p / y$ and $p / z$. Then $x^{2}=z^{2}-y^{2} \equiv 0(\bmod$ p), As $p / x^{2}$ then $p / x$
$\therefore \mathrm{p} / \operatorname{gcd}(\mathrm{x}, \mathrm{y}, \mathrm{z})$, which is a contradicting $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ being a primitive Pythagorean triple. Thus $\operatorname{gcd}(\mathrm{y}, \mathrm{z})=1$.

## Theorem 10:

Let ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ) be a primitive Pythagorean triples with x odd. Then there are $\mathrm{r}, \mathrm{s} \in \mathrm{N}$ with $\mathrm{r}>\mathrm{s}, \mathrm{gcd}(\mathrm{r}, \mathrm{s})=1$ and $r+s$ odd, such that $x=r^{2}-s^{2}, y=2 r s$ and $z=r^{2}+s^{2}$. Conversely, if $r, s \in N$ with $r>s, g c d(r, s)=1$ and $r+s$ odd, then ( $\mathrm{r} 2-\mathrm{s}^{2}, 2 \mathrm{rs}, \mathrm{r}^{2}+\mathrm{s}^{2}$ ) is a primitive Pythagorean triple.
Part I: Given: Let ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ) be a primitive a Pythagorean triples with x odd.
T.P.T: There are $r, s \in N$ with $r>s, g c d(r, s)=1$ and $r+s$ odd such that $x=r^{2}-s^{2}, y=2 r s$, and $z=r^{2}+s^{2}$

## Proof:

If x is odd, then y is even and z is odd. Let $\quad \mathrm{a}=\frac{z-x}{2}, \quad \mathrm{~b}=\frac{z-x}{2} \quad$ and $\mathrm{c}=\frac{y}{2}$
Then a,b,c $\in \mathrm{N}$, Also , $\mathrm{ab}=\frac{(z-x)(z+x)}{4}=\frac{z^{2}-x^{2}}{4}=\frac{y^{2}}{4}=\mathrm{c}^{2}$
Let $g=\operatorname{gcd}(a, b)$. Then $g /(a+b)$ and $g /(b-a)$, (ie) $g / z$ and $g / x$. As $g c d(x, z)$, Then $g=1$ (ie) $\operatorname{gcd}(a, b)=1$
Let $p$ be a prime factor of $a$. Then $p \nmid b, \operatorname{sov}_{p}(b)=0$. Hence, $v_{p}(a)=v_{p}(a)+v_{p}(b)=v_{p}(a b)=v_{p}\left(c^{2}\right)$
$v_{p}(a)=2 v_{p}(c)$ is even. Then a is a square. Similarly $b$ is a square. write $a=s^{2}$ and $b=r^{2} \quad$ where $r, s \in N$. Then $\operatorname{gcd}(r, s) / a$ and $\operatorname{gcd}(r, s) / b$ as $a$ and $b$ are coprime, $\operatorname{gcd}(r, s)=1$. Now, $x=b-a=r^{2}-s^{2}$

$$
\therefore \mathrm{r}>\mathrm{s}, \text { Also, } \mathrm{z}=\mathrm{a}+\mathrm{b}=\mathrm{r}^{2}+\mathrm{s}^{2}
$$

As $\mathrm{c}^{2}=\mathrm{ab},={ }^{\mathrm{r} 2 \mathrm{~s} 2} \mathrm{c}=\mathrm{rs}$ and $\therefore \mathrm{y}=2 \mathrm{rs}$. Finally as x is odd. Then $1 \equiv \mathrm{x}=\mathrm{r}^{2}+\mathrm{s}^{2} \equiv \mathrm{r}+\mathrm{s}$. (ie) $\mathrm{r}+\mathrm{s}$ is odd.

Part II: Given: Ifr, $\mathrm{s} \in \mathrm{N}$ with $\mathrm{r}>\mathrm{s}, \operatorname{gcd}(\mathrm{r}, \mathrm{s})=1$ and $\mathrm{r}+\mathrm{s}$ odd.
T.P.T: ( $\mathrm{r}^{2}-\mathrm{s}^{2}, \mathrm{r}^{2}+\mathrm{s}^{2}, 2 \mathrm{rs}$ ) is a primitive Pythagorean triple.

## Proof:

Let $x=r^{2}-s^{2}, y=2 r s$, and $z=r^{2}+s^{2}$, Certainly $y, z \in N$ and also $x \in N$ as $r>s>0$.
Also, $x^{2}+y^{2}=\left(r^{2}-s^{2}\right)^{2}+(2 r s)^{2}=r^{4}-2 r^{2} s^{2}+s^{4}+4 s r^{2}=r 4+2 r 2 s 2+s^{4}=r^{2}+s^{2}=z^{2}$.
Hence $(x, y, z)$ is a Pythagorean triple. Certainly $y$ is even. $x=r^{2}-s^{2} \equiv r-s \equiv r+s(\bmod 2), x$ is odd.
T.S.T: $(x, y, z)$ is a primitive Pythagorean triple. Examine $g=\operatorname{gcd}(x, z)$., As $x$ is odd , $g$ is odd. Also $g /\left(x^{2}+z^{2}\right)$ and $\mathrm{g} /\left(\mathrm{z}^{2}-\mathrm{x}^{2}\right.$ ) (ie) $\mathrm{g} / 2 \mathrm{~s}^{2}$ and $\mathrm{g} / 2 \mathrm{r}^{2}$
As $r$ and $s$ are coprime. Then $\operatorname{gcd}\left(2 \mathrm{r}^{2}, 2 \mathrm{~s}^{2}\right)=2, \therefore \mathrm{~g} / 2$
As g is odd $\mathrm{g}=1$. Hence $(\mathrm{x}, \mathrm{y}, \mathrm{z})$ is primitive Pythagorean triple.

## Sums of Squares:

For $\mathrm{k} \in \mathrm{N}$, let $\mathrm{S}_{\mathrm{k}}=\left\{\mathrm{a}_{1}^{2}+\ldots+\mathrm{a}_{\mathrm{k}}^{2}: \mathrm{a}_{1}, \ldots, \mathrm{a}_{\mathrm{k}} \in \mathrm{z}\right\}$ be the set of sums of k squares. Note that zero is allowed. For example $1=1^{2}+0^{2} \in S_{2}$. The sets $S_{2}$ and $S_{4}$ are closed under multiplication.

## Theorem 11:

If $m, n \in S_{2}$ then $m n \in S_{2} \&$ If $m, n \in S_{4}$ then $m n \in S_{4}$

## Proof:

Let $m, n \in S_{2}$, Then $m=a^{2}+b^{2}$ and $n=r^{2}+s^{2}$ where $a, b, r, s \in Z$, By the two-square formula, $\left(a^{2}+b^{2}\right)\left(r^{2}+s^{2}\right)=(a r-b s)^{2}+(a s+b r)^{2}$, it is immediate that $m n \in S_{2}$.

Let $m, n \in S_{4}$, Then $m=a^{2}+b^{2}+c^{2}+d^{2}$ and $n=r^{2}+s^{2}+t^{2}+u^{2}$ where $a, b, c, d, r, s, t, u \in Z$
By the four-square formula, $\left(\mathrm{a}^{2}+\mathrm{b}^{2}+\mathrm{c}^{2}+\mathrm{d}^{2}\left(\mathrm{r}^{2}+\mathrm{s}^{2}+\mathrm{t}^{2}+\mathrm{u}^{2}\right)=(\mathrm{ar}-\mathrm{bs}-\mathrm{ct}-\mathrm{du})^{2}+(\mathrm{as}+\mathrm{br}+\mathrm{cu}-\mathrm{dt})^{2}+(\mathrm{at}-\mathrm{bu}+\mathrm{cr}+\mathrm{ds})^{2}+\right.$ (au+bt-cs+dr) ${ }^{2}$, it is immediate that $\mathrm{mn} \in \mathrm{S}_{4}$.
Remark: The two-square theorem comes from complex no: $\left(a^{2}+b^{2}\right)\left(c^{2}+d^{2}\right)=|a+i b|^{2}|c+i d|^{2}=|(a+i b)(c+i d)|^{2}$

$$
=\mid(\mathrm{ac}-\mathrm{bd})+(\mathrm{ad}+\mathrm{bc})^{2}=(\mathrm{ac}-\mathrm{bd})+(\mathrm{ad}+\mathrm{bc})^{2}
$$

Restrict the possible factorizations of a sum of two squares. If $p$ is prime, and $n$ is an integer, then $v p(n)$

## Theorem 12:

Let p be a prime with $\mathrm{p} \equiv 3(\bmod 4)$ and let $n \in N$. If $n \in S_{2}$ then $v_{p}(n)$ is even.

## Proof:

Let $n=a^{2}+b^{2}$ with $a, b \in Z$, Suppose $p / n$, T.S.T: $p / a$ and $p / b$. Suppose $p / a$. Then there is $c \in Z$ with $\mathrm{ac} \equiv 1(\bmod \mathrm{p})$. Then $0 \equiv \mathrm{c}^{2} \mathrm{n}=\mathrm{c}^{2}\left(\mathrm{a}^{2}+\mathrm{b}^{2}\right)=(\mathrm{ac})^{2}+(\mathrm{bc})^{2} \equiv 1+(\mathrm{bc})^{2}(\bmod \mathrm{p}) \Rightarrow[-1 / \mathrm{p}]=1$
But $[-1 / p]=1$ when $p \equiv 3(\bmod 4)$, which is a contradiction. $\therefore \mathrm{p} / \mathrm{a}$
Similarly $p / b$, Thus $p^{2} /\left(a^{2}+b^{2}\right)=n$ and $n / p^{2}=(a / p)^{2}+(b / p)^{2} \in S_{2}$. Let $n \in S_{2}$ and $k=v_{p}(n)$, If $k>0$, then $k \geq 2$ and $n / p^{2} \in S_{2}$. Note that $v_{p}\left(n / p^{2}\right)=k-2$, Similarly, if $k-2>0($ ie $)$ if $k>2$ ), Then $k-2 \geq 2(($ ie $) k \geq 4)$ and $n / p 4 \in S_{2}$, Iterating this argument, find that if $k=2 r+1$ is odd. Then $n / p^{2 r} \in S_{2}$ and $v\left(n / p^{2 r}\right)=1$, which is a contradiction. $\therefore \mathrm{k}$ is even. Hence $\mathrm{v}_{\mathrm{p}}(\mathrm{n})$ is even.
Remark: If $n \in N$, write $n=r m^{2}$ where $m^{2}$ is the largest square dividing $n$ and $r$ is square free,(ie) either $r=1$ (or) $r$ is a product of distinct primes.

## Theorem 13:

Let p be a prime with $\mathrm{p} \equiv 1(\bmod 4)$. Then $\mathrm{p} \in \mathrm{S}_{2}$

## Proof:

If $\mathrm{p} \equiv 1(\bmod 4)$, Then $(-1 / \mathrm{p})=1, \therefore$ there is $u \in Z$ with $u^{2} \equiv-1(\bmod p)$. Let $A=\left\{\left(m_{1}, m_{2}\right) / m_{1}, m_{2} \in Z, 0 \leq\right.$ $\left.\mathrm{m}_{1}, \mathrm{~m}_{2}<\sqrt{p}\right\}$. Then A has $(1+\mathrm{s})^{2}$ elements, where is the integer part of $\sqrt{p}$ (i.,e) $\mathrm{s} \leq \sqrt{p}<\mathrm{s}+1$

Hence $|A|>p$. Form $m=\left(m_{1}, m_{2}\right) \in R^{2,}$ Define $\phi(m)=u_{1}+m_{2}$, Then $\phi$ is a linear map from $R^{2}$ to $R$. If $\mathrm{m} \in \mathrm{Z}^{2}$, then $\phi(\mathrm{m}) \in \mathrm{Z}$. As $|\mathrm{A}|>\mathrm{p}$, the $\phi(\mathrm{m})$ for $\mathrm{m} \in \mathrm{A}$ cannot all be distinct modulo p . Hence there are distinct $\mathrm{m}, \mathrm{n} \in \mathrm{A}$ with $\phi(\mathrm{m}) \equiv \phi(\mathrm{n})(\bmod \mathrm{p})$. Let $\alpha=\mathrm{m}-\mathrm{n}$. Then $\phi(\alpha)=\phi(\mathrm{m})-\phi(\mathrm{n}) \equiv 0(\bmod \mathrm{p})$. Let $\alpha=(\mathrm{a}, \mathrm{b})$, Then $\mathrm{a}=\mathrm{m}_{1}-\mathrm{n}_{1}$ where $0 \leq \mathrm{m}_{1}, \mathrm{n}_{1}<\sqrt{p}, \therefore|\mathrm{a}|<\sqrt{p}$, Similarly $|\mathrm{b}|<\sqrt{p}$, Then $\mathrm{a}^{2}+\mathrm{b}^{2}<2 \mathrm{p}$.

As $m \neq n$ then $\alpha \neq(0,0), \therefore a^{2}+b^{2}>0$, But $0 \equiv \phi(\alpha)=u a+b(\bmod p), \quad$ Hence $b \equiv-u a(\bmod p), \quad \therefore a^{2}+b^{2} \equiv a^{2}$ $+(-u a)^{2} \equiv a^{2}\left(1+u^{2}\right) \equiv 0(\bmod p) . \therefore a^{2}+b^{2}$ is a multiple of $p$ and $0<a^{2}+b^{2}<2 p$, Then $a^{2}+b^{2}=p, \therefore p \in S_{2}$

## Theorem 14:

Let $\mathrm{n} \in \mathrm{N}$ then $\mathrm{n} \in \mathrm{S}_{2}$ iff $\mathrm{v}_{\mathrm{p}}(\mathrm{n})$ is even whenever p is a prime congruent to 3 modulo 4 .

## Proof:

Given: $n \in S_{2}$, To Prove that: $v_{p}(n)$ is even whenever $p$ is a prime congruent to 3 modulo 4. If $n \in S_{2}, p$ is prime $\mathrm{p} \equiv 3(\bmod 4)$. Then $v_{p}(n)$ is even. Given: $v_{p}(n)$ is even whenever $p$ is a primer congruent to 3 modulo 4 .
T.P.T: $n \in S_{2}$, If $\mathrm{v}_{\mathrm{p}}(\mathrm{n})$ is even ,then $\mathrm{p}=\mathrm{rm}^{2}$ where each prime factor p of r is either2(or) congruent to 1 modulo 4. By theorem 2.2.3, all such $p$ lie in $S_{2}$. Hence $r \in S_{2}$. Hence $r=a 2+b^{2}$ where $a, b \in Z, \therefore n=r^{2}=(a m)^{2}+(b m)^{2} \in S_{2}$

## Theorem 15:

Let p be a prime .Then $\mathrm{p} \in \mathrm{S}_{4}$.

## Proof:

If $p \equiv 1(\bmod 4)$,then there are $a, b \in Z$ with $p=a^{2}+b^{2}+0^{2}+0^{2}$ so that $p \in S_{4}$ Also, $2=1^{2}+1^{2}+0^{2}+0^{2} \in S_{4}$ and $3=1^{2}+1^{2}+1^{2}+0^{2} \in S_{4}$, Assume that $p>3$ and that $p \equiv 3(\bmod 4)$. As a consequence $[-1 / p]=-1$, Let $W$ be the smallest positive integer with $[W / p]=-1$ Then $[W-1 / p]=1$ and $[-W / p]=[-1 / p][W / p]=1$, Hence there are $u, v \in Z$ with $w-1 \equiv$ $\mathrm{u}^{2}(\bmod \mathrm{p})$ and $-\mathrm{w} \equiv \mathrm{v}^{2}(\bmod \mathrm{p})$. Then $1+\mathrm{u}^{2}+\mathrm{v}^{2} \equiv 1+(\mathrm{w}-1)-\mathrm{w} \equiv 0(\bmod \mathrm{p})$.

Let $B=\left\{\left(\mathrm{m}_{1}, \mathrm{~m}_{2}, \mathrm{~m}_{3}, \mathrm{~m}_{4}\right) / \mathrm{m}_{1}, \ldots \ldots . ., \mathrm{m}_{4} \in \mathrm{Z}, 0 \leq \mathrm{m}_{1, \ldots \ldots \ldots . .}, \mathrm{m}_{4}<\sqrt{p}\right\}$ Then $B$ has $(1+\mathrm{S})^{4}$ elements , where S is the integer part of $\sqrt{ } \mathrm{p}$ (i.e) $\mathrm{S} \leq \sqrt{p}<\mathrm{S}+1$. Hence $|\mathrm{A}|>\mathrm{p}^{2,}$ For $\mathrm{m}=\left(\mathrm{m}_{1}, \mathrm{~nm}_{2}, \mathrm{~m}_{3}, \mathrm{~m}_{4}\right)$. Define $\psi(\mathrm{m})=$ $\left(u_{1}+v m_{2}+m_{3}-v m_{1}+u m_{2}+m_{4}\right)$. Then $\psi$ is a linear map from $R^{4}$ to $R^{2}$. If $m \in Z^{4}$ then $\psi(m) \in Z^{2,}$ Write $(a, b) \equiv$ $\left(a^{\prime}, b^{\prime}\right)(\bmod p)$. If $a \equiv a^{\prime}(\bmod p)$ and $b \equiv b^{\prime}(\bmod p)$. If a list $\left(a_{1}, b_{1}\right), \ldots,\left(a_{N}, b_{N}\right)$ of vectors in $z^{2}$ with $N>p^{2}$, Then there must be some $i$ and $j$ with $\left(a_{i}, b_{i}\right) \equiv\left(a_{j}, b_{j}\right)(\bmod p)$. This happens for the vectors $\psi(m)$ with $m \in B$. As $|B|>$ $\mathrm{p}^{2}$. There are distinct $\mathrm{m}, \mathrm{n} \in \mathrm{B}$ with $\psi(\mathrm{m}) \equiv \psi(\mathrm{n})(\bmod \mathrm{p})$. Let $\alpha=\mathrm{m}-\mathrm{n}$, Then $\psi(\alpha)=\psi(\mathrm{m})-\psi(\mathrm{n}) \equiv 0(\bmod \mathrm{p})$.

Let $\alpha=(\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d})$ then $\mathrm{a}=\mathrm{m}_{1}-\mathrm{n}_{1}$, where $0 \leq \mathrm{m}_{1}, \mathrm{n}_{1}<\sqrt{p} \therefore|\mathrm{a}|_{\sqrt{p}}$, Similarly $|\mathrm{b}|,|\mathrm{c}|,|\mathrm{d}|<\sqrt{p}$ then $\mathrm{a}^{2}+\mathrm{b}^{2}$ $+c^{2}+d^{2}<4 p$, As $m \neq n$ then $\alpha \neq(0,0,0,0) . \therefore a^{2}+b^{2}+c^{2}+d^{2}>0$. Now $(0,0) \equiv \phi(\alpha)=(u a+v b+c,-v a+u b+d)(\bmod$ p). Hence $c \equiv-u a+v b(\bmod p)$ and $d \equiv v a-u b(\bmod p)$. Then $a^{2}+b^{2}+c^{2}+d^{2} \equiv a^{2}+b^{2}+(-u a+v b)^{2}+(v a-u b)^{2}$

$$
=a^{2}+b^{2}+u^{2} a 2+v^{2} b^{2}+2 u v a b+v^{2} a^{2}+u^{2} b^{2}-2 u v a b=\left(1+u^{2}+v^{2}\right)\left(a^{2}+b^{2}\right) \equiv 0(\bmod p)
$$

As is a multiple of $p$ and $0<a^{2}+b^{2}+c^{2}+d^{2}<4 p$ then $a^{2}+b^{2}+c^{2}+d^{2} \in\{p, 2 p, 3 p\}$. when $a^{2}+b^{2}+c^{2}+d^{2}=p$ then certainly $p \in S_{4}$. To consider the bother some cases where $a^{2}+b^{2}+c^{2}+d^{2}=2 p(o r) 3 p$. Suppose that $a^{2}+b^{2}+c^{2}+d^{2}=2 p$.

Then $\mathrm{a}^{2}+\mathrm{b}^{2}+\mathrm{c}^{2}+\mathrm{d}^{2} \equiv 2(\bmod 4) \therefore$ two of $\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}$ are odd and other two even. Without loss of generality a and b are odd and c and d are even. then $\frac{1}{2}(a+b), \frac{1}{2}(a-b), \frac{1}{2}(c+d)$ and $\frac{1}{2}(c-d)$ are all integers. A simple computation gives $\left(\frac{a+b}{2}\right)^{2}+\left(\frac{a-b}{2}\right)^{2}+\left(\frac{c+d}{2}\right)^{2}+\left(\frac{c-d}{2}\right)^{2}=\frac{a^{2}+b^{2}+2 a b+a^{2}+b^{2}-2 a b}{4}+\frac{c^{2}+d^{2} 2 c d+c^{2}+d^{2}-2 c d}{4}$

$$
=\frac{a^{2}+b^{2}+c^{2}+d^{2}}{2}=p . \therefore p \in S_{4}
$$

Finally, suppose that $a^{2}+b^{2}+c^{2}+d^{2}=3 p$. Then $a 2+b 2+c 2+d 2$ is a multiple of 3 but not 9 . As $a^{2} \equiv 0(\operatorname{or}) 1(\bmod 3)$ then either exactly one (or) all four of $\mathrm{a}, \mathrm{b}, \mathrm{c}$ and d are multiples of 3 . But the latter case is impossible. (For then $a^{2}+b^{2}+c^{2}+d^{2}$ would be a multiple of 9$) . \therefore$ without loss of generality $3 / a$ and $b, c, d \equiv \pm 1(\bmod 3)$. By replacing $b$ by - $b$ etc. If necessary, let us assume that $B \equiv c \equiv d \equiv 1(\bmod 3)$. Then $\frac{1}{3}(b+c+d), \frac{1}{3}(a+b-c), \frac{1}{3}(a+c-d), \frac{1}{3}$ $(a+d-b)$, Are all integers and a simple computation gives
$\left(\frac{b+c+d}{3}\right)^{2}+\left(\frac{a+b-c}{3}\right)^{2}+\left(\frac{a+c-d}{3}\right)^{2}+\left(\frac{a+d-b}{3}\right)^{2}=\frac{b^{2}+c^{2}+d^{2}+2 b c++2 a d+2 b d}{9}+\frac{a^{2}+b^{2}+c^{2}+2 a b-2 b c-2 c a}{9}+\frac{a^{2}+c^{2}+d^{2}+2 a c-2 a d-2 a d}{9}$
$+\frac{a^{2}+d^{2}+b^{2}+2 a d-2 b d-2 b a}{9}=\frac{3\left(a^{2}+b^{2}+c^{2}+d^{2}\right)}{9}=p$

## Units in Integral Group Rings: <br> Units in $\mathbf{Z}\left[\mathbf{D}_{4}\right]$ :

In this section, we discuss $V=V\left(Z\left[D_{4}\right]\right)$, the group of units of augmentation 1 in $Z\left[D_{4}\right]$. Let $D_{4}$ be generated by $x$, $y$ with $X^{2}=y^{4}=c$ and $x y x=y^{3}$ Let $u \in Z\left[D_{4}\right]$ with $u=\left(a+b y+c y^{2}+d y 3^{3}\right)+\left(e+f y+g y 2^{2}+\right.$ $\left.h y^{3}\right) x, u=\alpha+\beta x$. Since $\{c, y 2\}-Z\left(D_{4}\right)$, the center of $D_{4}$. There is a ring homomorphism. $\lambda: Z\left[D_{4}\right] \rightarrow Z\left[D_{4}\right] / Z$ $\left[Z\left(D_{4}\right)\right] \cong Z\left[C_{2} \times C_{2}\right]$. Given by $\lambda(u)=(a+c)+(b+d) Y+(e+g) X+(f+h) X Y$. Where X,Y are the images of $x$, $y$ in the factor group $D_{4} / Z\left(D_{4}\right)=C_{2} x C_{2}$. Since $Z\left[C_{2} x_{2}\right]$ has only trivial units, then have four possible cases for units with augmentation 1, namely one of $a+c, b+d, e+g, f+h$ is 1 and the remaining 3 sums are 0 .

Denote the subsets of these units in $V$ by $V_{i}$ with $1 \leq i \leq 4$ respectively. Note that $y^{2} v^{i}=V_{i}$ for all I and also $\mathrm{V}_{2}=\mathrm{y} \mathrm{V}_{1}=\mathrm{V}_{1} \mathrm{y} ; \mathrm{V}_{3}=\mathrm{x} \mathrm{V}_{1}=\mathrm{V}_{1} \mathrm{x} ; \mathrm{V}_{4}=\mathrm{yx} \mathrm{V}_{1}=\mathrm{V}_{1} \mathrm{y}$. Thus these sets are in Bijective correspondence. $\therefore \mathrm{Up}$ to multiplication with a trivial unit. Assume that elements of V lie in $\mathrm{V}_{1}$, (ie) $a+c=1$ \& $b+d=e+g=f+h=0$. For $\mathrm{u} \in \mathrm{V}$, it follows directly from above equation that $\mathrm{u} \in \mathrm{V}_{1}$ iff $\mathrm{u}=1+\gamma\left(1-\mathrm{y}^{2}\right), \gamma=-$ $c+b y+e x+f y x$. Now let $u=\alpha+\beta x \in V_{1} \cdot \alpha \bar{\alpha}-\beta \bar{\beta}$ is a unit in $\mathrm{Z}\left[\mathrm{C}_{4}\right]$ fixed by the action of x . Since $\mathrm{Z}\left[\mathrm{C}_{4}\right]$ has only trivial units, $\alpha \bar{\alpha}-\beta \bar{\beta}= \pm 1$ (or) $\pm \mathrm{y}^{2}$. By (3.4), $\alpha \bar{\alpha}-\beta \bar{\beta}=(1+2 \delta)-(2 \delta) \mathrm{y}^{2}$. Where $\delta=\mathrm{b}^{2}+\mathrm{c}^{2}-\mathrm{e}^{2}-\mathrm{f}^{2}-\mathrm{c}$. Since $\delta$ is an integer, we must have that $\delta=0$, (ie) $\alpha \bar{\alpha}-\beta \bar{\beta}=\operatorname{det}(\phi(\mathrm{u})=1)$ and $\mathrm{e}^{2}+\mathrm{f}^{2}-\mathrm{b}^{2}=\mathrm{c}(\mathrm{c}-1)=-\mathrm{ac} \rightarrow$ (3.5)
Remark: $\phi(\mathrm{y})=\left(\begin{array}{cc}y & 0 \\ 0 & y^{3}\end{array}\right)$ and $\phi(\mathrm{x})=\left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right)$ Thus for $\mathrm{u} \in \mathrm{V}_{1} \cup \mathrm{~V}_{2}$, $\operatorname{det}(\phi(\mathrm{u}))=1$ and $\mathrm{V}_{1} \cup \mathrm{~V}_{2}$ is a normal subgroup of $V$ of index 2.

Similarly, $\operatorname{det}\left(\phi(u)\right.$ for $u$ in V3 (or) $V_{4}$ is -1 . Since, $-\mathrm{ac} \geq 0$, (3.5) shows that all units in $V_{1}$ lie on a surface, $X^{2}+Y^{2}-Z^{2}=-a c$. which is a hyperboloid of one sheet if ac $\neq 0$ and a cone if ac=0. Let $H_{k}$ denote the set of integer points on the hyperboloid $X^{2}+Y^{2}=Z^{2}+k$. Let $H_{n}$ denote the units with $c=n$ on $H_{n(n-1)}$. A point $(e, f, b)$ in $H_{c}$ is identified with the unit $u=1+\gamma\left(1-y^{2}\right)$ with $\gamma=-c+b y+e x+f y x$ as in above equation. Given any value of $c$, $H_{c}$ is non empty. Since $c(1-c)=2 m n$ for integers $m, n$ then $b=m+n, \quad c=m \& f=n$. Then we may identify $V_{1}$ with $\cup_{c} \in \mathrm{Z} H_{c}$, (ie) $\mathrm{V}_{1}$ is identified with the set of two copies of each hyperboloid $\mathrm{H}_{\mathrm{n}(\mathrm{n}-1)}$. One copy of $\mathrm{H}_{\mathrm{n}(\mathrm{n}-1)}$ corresponds to the units with $\mathrm{c}=\mathrm{n}$ and the other to the units with $\mathrm{c}=1-\mathrm{n}$. The following remark gives the multiplication for units in $\mathrm{V}_{1}$.
Remark: Let $u=(e, f, b) \in H_{c}$ and $v=\left(e^{\prime}, f^{\prime}, b^{\prime}\right) \in H_{c^{\prime}}$ then $u v=\left(e^{\prime \prime}, f^{\prime \prime}, b^{\prime \prime}\right) \in H_{c^{\prime \prime}}$ where $c^{\prime \prime}=c+c^{\prime}+2 b b^{\prime}-2 c c^{\prime}-2 e e^{\prime}-$ $2 f f^{\prime}=\left(b+b^{\prime}\right)^{2}+\left(c-c^{\prime}\right)^{2}-\left(e+e^{\prime}\right)^{2}-\left(f+f^{\prime}\right)^{2 ;} b^{\prime \prime}=\left(1-2 c^{\prime}\right) b+(1-2 c) b^{\prime}+2 \mathrm{fe}^{\prime}-2 \mathrm{f}^{\prime} ; e^{\prime \prime}=\left(1-2 c^{\prime}\right) e+(1-2 c) e^{\prime}+2 b^{\prime} f-2 b f^{\prime} ;$ $\mathrm{f}^{\prime \prime}=\left(1-2 \mathrm{c}^{\prime}\right) \mathrm{f}+(1-2 \mathrm{c}) \mathrm{f}^{\prime}+2 \mathrm{be}^{\prime}-2 \mathrm{eb}^{\prime}$;
The multiplication formula may be interpreted as

$$
\left.\left[\begin{array}{c}
e^{e} \\
f^{\prime \prime} \\
b^{\prime \prime}
\end{array}\right]=\left(1-2 c^{\prime}\right)\left[\begin{array}{l}
e \\
f \\
b
\end{array}\right]+(1-2 c)\left[\begin{array}{c}
e^{\prime} \\
f^{\prime} \\
b^{\prime}
\end{array}\right]+2\left[\begin{array}{ccc}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -1
\end{array}\right]\left[\begin{array}{c}
e \\
f \\
f
\end{array}\right] \times\left[\begin{array}{c}
e^{\prime} \\
f^{\prime} \\
b^{\prime}
\end{array}\right]\right]
$$

Thus $u, v \in v_{1}$ commute if they represent parallel vectors in $Z^{3}$.

## Theorem 16:

Let $u=(e, f, b) \in H_{c}$ and let $u n=\left(e_{n}, f_{n}, b_{n}\right) \in H_{c n}$. For $n$ a positive integer, $\left(e_{n}, f_{n}, b_{n}\right)=\alpha_{n}(e, f, b$,$) for some$ integer $\alpha_{n}$ with $\alpha_{1}=1, \alpha_{2}=2(1-2 \mathrm{c})$,etc. Furthermore the sequence $\left|\alpha_{1}\right|,\left|\alpha_{2}\right|, \ldots$. is strictly increasing. For n a positive integer, $c_{n}=\beta_{n} c$ for some integer $\beta_{n}$ where $\beta_{1}=1, \beta_{2}=4 a$, etc. If $\mathrm{ac} \neq 0$, then the sequence $|\beta|,|\beta|, \ldots \ldots \ldots$ is strictly increasing. If $e=0$, then $e_{n}=0$ for all n.if $a=0, c=1$ then $c_{n}=0$ if $n$ is even, and $c_{n}=1$ if $n$ is odd.

## Proof:

First show that $\left(e_{n}, f_{n}, b_{n}\right)=\alpha_{n}(e, f, b)$ and $e_{n}=\beta_{n} c$ for integers $\alpha_{n}, \beta_{n}$. The proof is by induction on $n$. If $n=2$, then $\alpha_{2}=2(a-c)=2(1-2 c)$. Now suppose that for $n=k-1$, $\left(e_{k-1}, f_{k-1}, b_{k-1}\right)=\alpha_{k-1}(e, f, b)$. Then $\left(e_{k}, f_{k}, b_{k}\right)=\left(\left(1-2 c_{k-}\right.\right.$ $\left.\left.{ }_{1}\right)+(1-2 c) \alpha_{k-1}\right)(e, f, b)$, Similarly, since $c_{2}=4 a c$. Again using induction on $n$, suppose that $c_{k-1}=\beta_{k-1} c$. Then $c_{k}=c+\beta_{k-}$ ${ }_{1}(1-2 \mathrm{c}) \mathrm{c}+2 \alpha_{\mathrm{k}-1}$ ac, so that, $\beta_{\mathrm{k}}=1+\beta_{\mathrm{k}-1}(1-2 \mathrm{c})+2 \mathrm{a} \alpha_{\mathrm{k}-1}$. Now suppose that $\mathrm{ac} \neq 0$, so that $|\mathrm{a}-\mathrm{c}|>1$. Note that we have shown that $\alpha_{n}=1-2 \beta_{n-1} c+(1-2 c) \alpha_{n-1} ; \beta_{n}=1+\beta_{n-1}(1-2 c)+2 \alpha_{n-1}$ Next to claim that for $n \geq 2, \alpha_{n} \& \beta_{n}$ have the same sign and $\left|\alpha_{n}\right|>\left|\alpha_{n-1}\right|,\left|\beta_{\mathrm{n}}\right|>\left|\beta_{\mathrm{n}-1}\right|$, Note that $\alpha_{1}=1, \beta=1, \alpha_{2}=2(\mathrm{a}-\mathrm{c}), \beta_{2}=4 \mathrm{a}$ and proceed by induction. Suppose that $\alpha_{k-1}$ and $\beta_{k-1}$ hae the same sign. Since $-2 \mathrm{c}, \mathrm{a}-\mathrm{c}$ and 2 a all have the same sign. Then the summands $2 \mathrm{c} \beta_{\mathrm{k}-1},(\mathrm{a}-\mathrm{c}) \alpha_{\mathrm{k}}$ ${ }_{1},(\mathrm{a}-\mathrm{c}) \beta_{\mathrm{k}-1}, 2 \alpha_{\mathrm{k}-1} \operatorname{in}(3.6),(3,7)$ have same sign. If these are positive. Then clearly $\alpha_{\mathrm{k}}, \beta_{\mathrm{k}}$ are positive and greater than $\left|\alpha_{k-1}\right|, \beta_{k-1} \mid$. If the summands are all negative. Then since $\left|2 c \beta_{k-1}\right|>1$ and $\left|2 a \alpha_{k-1}\right|>1$. Still have that $\left|\alpha_{k}\right|, \beta_{k} \mid$ are greater than $\left|\alpha_{k-1}\right|,\left|\beta_{\mathrm{k}-1}\right|$ respectively. Now let $\mathrm{ac}=0$. If $\mathrm{c}=0$, then the multiplication formula immediately yields that $\alpha_{n}=n . c_{n}=0$ for all $n$. If $c=1$, then again by Remark 3.1.2 and a simple induction argument, the sequence of $\alpha_{n}$ is $1,-2,3,-4, \ldots$. and the sequence of integers $c_{n}$ is $1,0,1,0,1, \ldots \ldots$.

## Theorem 17:

$\checkmark$ The set $V_{2}=y V_{1}$ has no units of order 2, but has non -trivial units of order 4. A unit $u \in V_{2}, u=y^{3}+\gamma(1-$ $y^{2}$ ) with $\gamma=a+b y+e x+$ fyx is of order 4 . iff $a=0$ and $(e, f)$ is an integer point on the circleX2 $+Y 2=b(b-$ 1).
$\checkmark$ The sets $V_{3} \& V_{4}$ have no units of order 4, but have non-trivial units of order 2. For $u==^{y 2 x}+\gamma\left(1-y^{2}\right)$ in $V_{3}, \gamma$ as above, then $u$ has order 2 iff $a=0$, and (b,f) is a point on the hyperpola $X^{2}-Y^{2}=e^{2}-e$. For $u=y 3 x+\gamma\left(1-y^{2}\right)$ in $V_{4} \cdot \gamma$ as above, then $u$ has order 2 iff $a=0$, and $(b, e)$ is a point $o n X^{2}-Y^{2}=f^{2}-f$

## Proof:

Let $u=\alpha+\beta x \in V_{2}$. Suppose first that $u^{2}=1$. By the theorem "Let $D$ be the image of $Z[G]$ under $\phi$ so that the unit group of $Z[G]$ is isomorphic to the group of matrices in $D$ with determinant a unit in $Z[H]$, (ie) $\mathrm{u}(\mathrm{Z}[\mathrm{G}])=\left\{u=\alpha+\frac{\beta x}{\alpha \bar{\alpha}}-\beta \bar{\beta} \in u(Z[H])\right\}$. If $u=\alpha+\beta \mathrm{x} \in \mathrm{u}(\mathrm{Z}[\mathrm{G}])$ with $\alpha \bar{\alpha}-\beta \bar{\beta}=w \in \tilde{u}(Z[H])$ then $\mathrm{u}-1=\mathrm{W}-1(\alpha-\beta X)$ " $\Rightarrow \alpha=\bar{\alpha}, \beta=-\beta$ Thus $\mathrm{b}=\mathrm{d}$, contradicting $\mathrm{b}+\mathrm{d}=1$. Now let $\mathrm{u}^{2}=\mathrm{y}^{2}=\mathrm{u}^{2}, \Rightarrow \alpha^{2}=\bar{\alpha}^{2}$ So that either $\mathrm{b}=\mathrm{d}$, a contradiction. (or) $a=c=0$. Straight forward computation shows that if $a=c=0, u^{2}=y^{2}$ iffe ${ }^{2}+f^{2}=b^{2}-b$. Now let $u=\alpha+\beta x \in V_{3}$

Suppose first that $u^{2}=y^{2}$. For $u \in V_{3}$, $\operatorname{det}(\phi(u))=-1, / u-1=-\bar{\alpha}+\beta x$. Then $u^{2}=u^{-2}$, $\Rightarrow$ either $b=d=0$ (or) $\mathrm{a}=\mathrm{c}=0$. If $\mathrm{a}=\mathrm{e}=0$, again as above, $\mathrm{E}^{2}+\mathrm{f}^{2}=\mathrm{b}(\mathrm{b}-1)$. But the left side of this equation is odd and the right side is even. Which is a contradiction. A Similar contradiction arises if $b=d=0$. Now suppose that $u=u-1$. Then $\alpha=-\bar{\alpha}$ or equivalently $\mathrm{a}=0$. Now let $\mathrm{u}^{2}=\mathrm{y}^{2}=\mathrm{u}-2, \Rightarrow \alpha 2=\bar{\alpha} 2$ so that either $\mathrm{b}=\mathrm{d}$, a contradiction, (or) $\mathrm{a}=\mathrm{c}=0$. Straight forward computation shows that if $a=c=0, u^{2}=y^{2}$ iff $e^{2}+f^{2}=b^{2}-b$. Now let $u=\alpha+\beta x \in V_{3}$. Suppose first that $u^{3}=y^{2}$. For $\mathrm{u} \in \mathrm{V}_{3}$, $\operatorname{Let}(\phi(\mathrm{u}))=-1$, / $\mathrm{u}-1=-\bar{\alpha}+\beta \mathrm{x}$, Then $\mathrm{u}^{2}=\mathrm{u}^{-2}$, $\Rightarrow$ either $\mathrm{b}=\mathrm{d}=0$ (or) $\mathrm{a}=\mathrm{c}=0$. If $\mathrm{a}=\mathrm{c}=0$, again as above, $\mathrm{e}^{2}+\mathrm{f}^{2}=\mathrm{b}(\mathrm{b}-1)$. But the left side of this equation is odd and the right side is even. Which is a contradiction. A
similar contradiction arises if $\mathrm{b}=\mathrm{d}=0$. Now suppose that $\mathrm{u}=\mathrm{u}^{-1}$. Then $\alpha=\bar{\alpha}$ or equivalently $\mathrm{a}=0$ and $\alpha \bar{\alpha}=\beta \bar{\beta}+1$ or equivalently $b^{2}=f^{2}+e^{2}-e$. The argument for $V_{4}$ is similar.
Remark: A subgroup of $\left.\mathrm{V}\left(\mathrm{Z}_{[ } \mathrm{D}_{4}\right]\right)$ isomorphic to the Klein 4 -group k must be generated by $\mathrm{y}^{2}$ and a unit of order 2 in $V_{3}$ (or) $V_{4}$. For suppose $u$,v generate a copy of $k$ with $u \in V_{3}$ and $v \in V_{4}$. Then $u v \in V_{2}$ which has no units of order 2.Thus $u$,v both lie in $V_{3}(o r) V_{4}$, and $u v=y^{2}$.

## Integer Points on a Hyperoloid:

Now describe a method for finding integer points on $\mathrm{H}_{\mathrm{k}}$ for various k based on "growing the tree of primitive Pythagorean triples from $(3,4,5)$ ". A point $p=(a, b, c) \in H_{0}$ satisfies $x^{2}+y^{2}=z^{2}$. If $a, b, c$ are positive, then $(a, b, c)$ is called a Pythagorean triple. Every Pythagorean tripled is a multiple of a primitive Pythagorean triple, (ie) one in which $\operatorname{gcd}(\mathrm{p})=\operatorname{gcd}(\mathrm{a}, \mathrm{b}, \mathrm{c})=1$. In order to construct all primitive Pythagorean triples, it suffices to find all primitive Pythagorean triples ( $\mathrm{a}, \mathrm{b}, \mathrm{c}$ ) with $\mathrm{a}, \mathrm{c}$ odd and b even, since all others are obtained by switching $\mathrm{a}, \mathrm{b}$. The "tree" of such triples with a,b,c positive grown from the "seed" ( $3,4,5$ ) is well known ;review its construction. Let $\mathrm{I}_{\mathrm{i}}, \mathrm{i}=1,2,3$ and $\mathrm{I}_{1.2}$ be the matrices representing reflections in the planes $\mathrm{X}=0, \mathrm{Y}=0, \mathrm{Z}=0$ and $\mathrm{X}=\mathrm{Y}$ respectively. Let, U,A,D be the transformations with matrices

$$
A=\left(\begin{array}{lll}
1 & 2 & 2 \\
2 & 1 & 2 \\
2 & 2 & 3
\end{array}\right)
$$

Remark: Construct the integer points on $\mathrm{H}_{\mathrm{k}}, \mathrm{k} \neq 0$, in a similar manner. Let $\mathscr{F}$ be a group of linear transformations on Z 3 which maps $\mathrm{H}_{\mathrm{k}}$ to itself. Define an equivalence relation $\sim_{\mathscr{F}}$ on $\mathrm{H}_{\mathrm{k}}$ by $\mathrm{p} \sim_{\mathscr{F}} \mathrm{QiffQ}=\mathrm{T}(\mathrm{p})$ for some $\mathrm{T} \in_{\mathscr{F}}$. Denote the equivalence class of p by $[p]_{\mathscr{F}}$. Now define groups of transformations on $\mathrm{H}_{\mathrm{k}}$ as follows
$\checkmark \quad$ Let R be generated by $\mathrm{I}_{1.2}, \mathrm{I}_{\mathrm{i}}, \mathrm{i}=1,2,3 \cdot \mathrm{R} \cong \mathrm{D}_{4} \mathrm{XC}_{2}$.
$\checkmark \quad$ Let R be generated by $\mathrm{I}_{3}$ and $\mathrm{I}_{\mathrm{i} \cdot 2} \mathrm{R}^{\prime} \cong \mathrm{C}_{2} \mathrm{XC}_{2}$.
$\checkmark$ Let $S$ be generated by the U,A,D or equivalently by $A, I_{1}, \mathrm{I}_{2}$
$\checkmark \quad$ Let $S$ be generated by $S$ and $R^{\prime}$.
Let $(x, y, z) \in H_{k}$ with $k$ not a square and $x=2 m+1$ odd. Then $o \neq t=z-y$, Letting $s=z+y$ we have $t s=x 2-k$. We identify points with $x$ odd in $H_{k}$ with the set of pairs $P_{k}=\{m, t\} / m \in Z, t$ divides $\left.(2 m+1) 2-k\right\}$ via.

$$
\left(\begin{array}{l}
x \\
y \\
z
\end{array}\right)=\binom{\frac{(2 m+1)^{2}-k-t^{2}}{2 t}}{\frac{(2 m+1)^{2}-k+t^{2}}{2 t}}=\left(\begin{array}{c}
2 m+1 \\
\frac{s-t}{2} \\
\frac{s+t}{2}
\end{array}\right)
$$

Now identify points $(x, y, z) \in H_{k}$ with $x=2 m$ even, $k$ not a square, in a similar way with the set of pairs $2_{\mathrm{k}}=\{(\mathrm{m}, \mathrm{t}) / \mathrm{m} \in \mathrm{Z}$, t divides $(2 \mathrm{~m}) 2-\mathrm{k}\}$ via

$$
\left(\begin{array}{l}
x \\
y \\
z
\end{array}\right)=\left(\begin{array}{c}
2 m+1 \\
\frac{(2 m)^{2}-k-t^{2}}{2 t} \\
\frac{(2 m)^{2}-k+t^{2}}{2 t}
\end{array}\right)=\left(\begin{array}{c}
2 m \\
\frac{s-t}{2} \\
\frac{s+t}{2}
\end{array}\right)
$$

The linear transformations $U, A, D$ on $H_{k}$ define maps (which we also denote $U, A, D$ ) on $P_{k}$ and $2_{k}$, $y$
$\mathrm{U}(\mathrm{m}, \mathrm{t})=(\mathrm{m}+\mathrm{t}, \mathrm{t})$
and $\quad A(m, t)=(m+s, s) \quad$ for $(m, t) \in P_{k}(o r) 2_{k}$
$D(m, t)=(s-m-1, s) \quad$ for $(m, t) \in p_{k}$
$\mathrm{D}(\mathrm{m}, \mathrm{t})=(\mathrm{s}-\mathrm{m}, \mathrm{s}) \quad$ for $(\mathrm{m}, \mathrm{t}) \in 2_{\mathrm{k}}$
Remark: If ( $\mathrm{m}, \mathrm{t}$ ) $\in \mathrm{P}_{\mathrm{k}}$ (or) $2_{\mathrm{k}}$ corresponds to $(\mathrm{x}, \mathrm{y}, \mathrm{z}) \in \mathrm{H}_{\mathrm{k}}$, then ( $\mathrm{m}, \mathrm{s}$ ) corresponds to ( $\mathrm{x},-\mathrm{y}, \mathrm{z}$ ), (m,-t) corresponds to( $\mathrm{x},-\mathrm{y},-\mathrm{z}$ ).
Remark: If $k$ is a square, say $k=K^{2}$, then any point $( \pm K, y, y)$ lies on $H_{k}$ so that the bijective correspondence between $H_{k}$ and $P_{k} \cup 2_{k}$ fails.
Remark: Let $\mathrm{p}=(\mathrm{x}, \mathrm{y}, \mathrm{z}) \in \mathrm{H}_{\mathrm{k}}$.
$\checkmark$ If $\mathrm{k} \equiv 0 \bmod 4$, then either $\mathrm{x}, \mathrm{y}, \mathrm{z}$ are all even (and thus $\operatorname{gcd}(\mathrm{p}) \geq 2)$.(or) z is odd, and x , y have different parity, then
$\checkmark$ If $\mathrm{k} \equiv 1 \bmod 4$, then either $\mathrm{x}, \mathrm{y}, \mathrm{z}$ are all odd, (or) z is even and $\mathrm{x}, \mathrm{y}$ have different parity.
$\checkmark \quad$ If $\mathrm{k} \equiv 2 \bmod 4$, then z must be even and x , y both odd.
$\checkmark \quad$ If $\mathrm{k} \equiv 3 \bmod 4$, then z must be odd and x , y other even.

## Theorem 18:

If $\mathrm{P}_{\mathrm{k}} \neq \phi$, then for any $m \in Z$, there exists $t$ such that $(m, t) \in P_{k}$. \& If $2_{k} \neq \phi$, then for any $m \in Z$, there exists $t$ such that $(\mathrm{m}, \mathrm{t}) \in 2_{\mathrm{k}}$.

## Proof:

Let $\mathrm{P}_{\mathrm{k}}=\phi, \mathrm{m} \in \mathrm{Z}, \mathrm{x}=2 \mathrm{~m}+1$. If k is even. Then $\mathrm{st}=\mathrm{x}^{2}-\mathrm{k}$ is odd $\therefore$ Let $\mathrm{t}=1, \mathrm{~S}=\mathrm{x}^{2}-\mathrm{k}$, To obtain values of $\mathrm{y}, \mathrm{z}$. If k is odd, Then $\mathrm{k} \equiv 1 \bmod 4, \therefore 4$ divides $\mathrm{z}^{2}=\mathrm{y}^{2}$

Choose $t=2$ and $s$ even. The proof of (ii) is similar and use the fact that here cannot have $k \equiv 2 \bmod 4$.

## Conclusion:

This paper deals with Pythagorean Triples and primitive Pythagorean triples. Some theorems based on these are also discussed. Also it deals with characterization of primitive Pythagorean triples and lagrange's square theorem. And then describes a simple method for finding units of group rings of the form $\mathrm{Z}[\mathrm{G}]=\mathrm{Z}[\mathrm{H}]$ $=\mathrm{Z}\left[\mathrm{C}_{2}\right]$ for H an Abelian group and apply this to the case $\mathrm{G}=\mathrm{D}_{4}$, the dihedral group of order 8 .
