We construct the most general non-extremal spherically symmetric instanton solution of a gravity-dilaton-axion system with $SL(2, R)$ symmetry, for arbitrary euclidean spacetime dimension $D \geq 3$. A subclass of these solutions describe completely regular wormhole geometries, whose size is determined by an invariant combination of the $SL(2, R)$ charges.

Our results can be applied to four-dimensional effective actions of type II strings compactified on a Calabi-Yau manifold, and in particular to the universal hypermultiplet coupled to gravity. We show that these models contain regular wormhole solutions, supported by regular dilaton and RR scalar fields of the universal hypermultiplet.

1 The action

This paper contains a summary of [1]. In addition, we demonstrate the existence of regular wormhole solutions in the universal hypermultiplet, which is present in the low-energy effective action of type II string theories compactified on a Calabi-Yau manifold. Wormhole solutions from Calabi-Yau compactifications were also found in [2]. The main difference with our solution is that in our case we also include RR fields, and furthermore, our solution is regular in the complete domain of the wormhole geometry.

We start with the action of a gravity-dilaton-axion system in D -spacetime dimensions. In Minkowski space, the Lagrangian is

$$\mathcal{L}_M = \frac{1}{2} \sqrt{|g|} \left[R - \frac{1}{2} (\partial\phi)^2 - \frac{1}{2} e^{b\phi} (\partial\chi)^2 \right], \quad (1)$$

where b is an arbitrary dilaton coupling parameter. This Lagrangian has an $SL(2, R)$ group of symmetries. They can be realized as modular transformations on the complex field

$$\tau \equiv \frac{b}{2} \chi + i e^{-b\phi/2}, \quad \tau \rightarrow \frac{\alpha\tau + \beta}{\gamma\tau + \delta}, \quad \alpha\delta - \beta\gamma = 1, \quad (2)$$

and is valid for any nonzero value of the dilaton coupling b .

This theory occurs for example as the scalar section of IIB supergravity in $D = 10$ Minkowski space-time with dilaton-coupling parameter $b = 2$. Other values of b can arise when considering (truncations of) compactifications of II supergravity. The main example we will discuss here is that of the universal hypermultiplet, that arises after compactifying type IIA strings on a (rigid) Calabi-Yau threefold down to $D = 4$. This hypermultiplet contains four scalars, ϕ and σ coming from the NS sector, and ψ and φ coming from the RR sector. The four-dimensional Lagrangian can be written as

$$\mathcal{L}_M = \frac{1}{2} \sqrt{|g|} \left[R - \frac{1}{2} (\partial\phi)^2 - \frac{1}{2} e^\phi ((\partial\psi)^2 + (\partial\varphi)^2) - \frac{1}{2} e^{2\phi} (\partial\sigma + \psi\partial\varphi)^2 \right]. \quad (3)$$

The scalar symmetry group is now $SU(2, 1)$, but contains various inequivalent $SL(2, R)$ subgroups. For instance, if we set both $\sigma = \psi = 0$, we get (1) which $b = 1$ whereby φ is identified with χ . If we set $\psi = \varphi = 0$, we have $b = 2$ and σ is identified with χ . By writing down the field equations for (3), it is easy to see that these truncations are consistent. Extremal instantons in the universal hypermultiplet have been discussed in detail in [3–5], and correspond to wrapped (euclidean) membranes along three-cycles, or wrapped NS5-branes along the entire Calabi-Yau. These two cases correspond to $b = 1$ and $b = 2$ respectively. Using the results obtained in [1], we will here generalize this to the non-extremal case, and show that there are interesting and new solutions that have the spacetime geometry of a wormhole.

To discuss instantons, we first have to perform a Wick rotation. This rotation is best understood by dualizing the axion into a $(D - 2)$ -form potential. One then finds that under a Wick rotation, $\chi \rightarrow i\chi$. The Euclidean Lagrangian corresponding to (1) is then

$$\mathcal{L}_E = \frac{1}{2} \sqrt{g} \left[R - \frac{1}{2} (\partial\phi)^2 + \frac{1}{2} e^{b\phi} (\partial\chi)^2 \right], \quad (4)$$

with all fields real. Notice that in the scalar formulation, as opposed to the formulation with the $(D - 1)$ -form field strength, the contribution to the action coming from the scalar sector is not positive definite. For $b = 2$ and $D = 10$ this is the gravity-scalar part of Euclidean IIB supergravity, in which the D-instanton can easily be found as a solution of the Euclidean equations of motion [6, 7]. The non-extremal solutions were found in [1], and we repeat them in the next section.

As already explained, compactifications of string theory can give rise to other values of b . The Euclidean version of the universal hypermultiplet Lagrangian (3) can best be understood in terms of the double-tensor multiplet formulation, in which φ and σ are dualized into two antisymmetric tensors [3]. After a Wick rotation, $\varphi \rightarrow i\varphi, \sigma \rightarrow i\sigma$, and the Euclidean Lagrangian for the universal hypermultiplet becomes

$$\mathcal{L}_E = \frac{1}{2} \sqrt{|g|} \left[R - \frac{1}{2} (\partial\phi)^2 - \frac{1}{2} e^\phi ((\partial\psi)^2 - (\partial\varphi)^2) + \frac{1}{2} e^{2\phi} (\partial\sigma + \psi\partial\varphi)^2 \right]. \quad (5)$$

Notice that the two truncations, $\psi = \sigma = 0$ and $\psi = \varphi = 0$, both fall into the class of (4), in which we have $b = 1$ and $b = 2$ respectively.

There are three conserved currents for the $SL(2, R)$ transformations in the Euclidean model, satisfying $\nabla_\mu j^\mu = 0$. The corresponding charges are denoted by q_3, q_+ and q_- , and are normalized as specified in [1]. They transform under $SL(2, R)$ in such a way that the combination

$$q^2 \equiv q_3^2 - q_+ q_- , \quad (6)$$

is invariant [1, 8]. The three conjugacy classes of $SL(2, R)$ then correspond to $q^2 < 0, q^2 = 0$ and $q^2 > 0$. The extremal solutions will have $q^2 = 0$, the non-extremal $q^2 \neq 0$. The wormhole solutions will have $q^2 < 0$. For later convenience, it is useful to define the quantity

$$c \equiv \sqrt{\frac{2(D - 1)}{D - 2}} , \quad (7)$$

which will appear explicitly in the instanton solutions below.

2 Instanton solutions

We search for generalised instanton solutions with manifest $SO(D)$ symmetry,

$$ds^2 = e^{2B(r)}(dr^2 + r^2 d\Omega_{D-1}^2), \quad \phi = \phi(r), \quad \chi = \chi(r). \quad (8)$$

The standard D-instanton solution [6] is obtained for the special case that $B(r)$ is constant. Other references on generalised instantons and wormholes that are related to our work are [2, 9–17]. To obtain an $SO(D)$ symmetric generalised instanton solution, we allow for a non-constant $B(r)$ and solve the field equations following from the Euclidean action (4). This was done in detail in [1]. Here we summarise the result.

The solution can be written in a compact form by using a harmonic function $H(r)$ over a conformally flat space with metric as given in (8),

$$H(r) = \frac{bc}{2} \log(f_+(r)/f_-(r)), \quad B(r) = \frac{1}{D-2} \log(f_+ f_-), \quad f_{\pm}(r) = 1 \pm \frac{q}{r^{D-2}}, \quad (9)$$

The general instanton solution can then be written as

$$\boxed{\begin{aligned} ds^2 &= \left(1 - \frac{q^2}{r^{2(D-2)}}\right)^{2/(D-2)} (dr^2 + r^2 d\Omega_{D-1}^2), \\ e^{b\phi(r)} &= \left(\frac{q_-}{q} \sinh(H(r) + C_1)\right)^2, \\ \chi(r) &= \frac{2}{b q_-} (q \coth(H(r) + C_1) - q_3). \end{aligned}} \quad (10)$$

This solution is valid for any value¹ of $b \neq 0$. The integration constant C_1 can be traded for the asymptotic value of the dilaton that we will later identify with the string coupling constant. Notice also the explicit dependence on the $Sl(2, R)$ charges q_3, q_- and q_+ . The solutions (10) are valid both for $q^2 \equiv q_3^2 - q_- q_+$ positive, negative and zero, corresponding to the three conjugacy classes of $SL(2, R)$. We now discuss these three cases separately:

- $q^2 > 0$: Black Holes

In this case q is real and the solution is given by (10) with all constants real. However, the metric becomes imaginary below a critical radius

$$r^{D-2} < r_c^{D-2} = q. \quad (11)$$

One can check that there is a curvature singularity at $r = r_c$, which happens at strong string coupling: $e^{\phi(r)} \rightarrow \infty$ as $r \rightarrow r_c$.

Between $r = r_c$ and $r = \infty$, H varies between ∞ and 0, and with an appropriate choice of C_1 , i.e. a positive value of C_1 , the scalars have no further singularities in this domain. Thus one might hope to have a modification of this solution by higher-order contributions to the effective action of IIB string theory [13]. Alternatively, one can consider the possible resolution of this singularity upon uplifting to one higher dimension. In [1], we showed that this indeed happens for the special case of

$$b \geq \sqrt{\frac{2(D-2)}{D-1}}, \quad (12)$$

¹ The case $b = 0$ is treated in [18].

equivalent to $bc \geq 2$. Upon uplifting, this becomes a non-extremal dilatonic black hole. The case when $bc = 2$ lifts up to a (non-dilatonic) Reissner-Nordström black hole with mass and charge given by

$$Q = -2q_-, \quad M = 2\sqrt{q^2 + q_-^2} \quad \Rightarrow \quad q^2 = \frac{M^2 - Q^2}{4}. \quad (13)$$

Hence, the $q^2 > 0$ solutions with $bc \geq 2$ are spatial sections of a higher-dimensional (Lorentzian) black hole solution. The case of $bc < 2$ cannot be uplifted and remain singular instanton solutions in D -dimensions. In Einstein frame, these geometries are singular wormholes that are pinched at the selfdual radius $r_{sd} = r_c$ [1].

In the case of $q^2 > 0$, there is an interesting limit in which $q_- \rightarrow 0$. This yields a solution with only two independent integration constants, q_+ and q^2 . The range of validity of this solution is equal to that of the above solution with $q_- \neq 0$: it is well-defined for $r > r_c$, while at $r = r_c$ the metric has a singularity and the dilaton blows up. The singularity can be resolved upon uplifting for all values of $bc \geq 2$ to Schwarzschild black holes, with mass $M = 2q$. More details can be found in [1].

• $q^2 = 0$: Extremal instantons

We now consider the limit $q^2 \rightarrow 0$ of the general solution (10), after rescaling the constant C_1 with a factor q to make the limit well-defined. Taking the limit yields the extremal solution:

$$ds^2 = dr^2 + r^2 d\Omega_{D-1}^2, \quad e^{b\phi(r)/2} = h \quad \chi(r) = \frac{2}{b} \left(h^{-1} - \frac{q_3}{q_-} \right), \quad (14)$$

where $h(r)$ is the harmonic function:

$$h(r) = g_s^{b/2} + \frac{bcq_-}{r^{D-2}}, \quad (15)$$

and g_s is the asymptotic value of the dilaton at infinity.

This is the extremal D-instanton solution of [6]. This solution is regular over the range $0 < r < \infty$ provided one takes both g_s and bcq_- positive; at $r = 0$ however, the harmonic function blows up and the scalars are singular. Similar to the case of $q^2 > 0$, these singular solutions can be lifted to higher dimensions where, e.g. for $bc = 2$, they become extremal Reissner-Nordström black holes.

• $q^2 < 0$: Wormholes

In this case q is imaginary. To obtain a real solution we must take C_1 to be imaginary. We therefore redefine

$$q \rightarrow i\tilde{q} \quad C_1 \rightarrow i\tilde{C}_1, \quad (16)$$

such that \tilde{q} and \tilde{C}_1 are real. One can now rewrite the solution (10) by using the relation

$$\log(f_+/f_-) = 2 \operatorname{arctanh}(q/r^{D-2}), \quad (17)$$

and, next, replacing the hyperbolic trigonometric functions by trigonometric ones in such a way that no imaginary quantities appear. We thus find that, for $q^2 < 0$, the general solution (10) takes the following form:

$$\begin{aligned} ds^2 &= \left(1 + \frac{\tilde{q}^2}{r^{2(D-2)}}\right)^{2/(D-2)} (dr^2 + r^2 d\Omega_{D-1}^2), \\ e^{b\phi(r)} &= \left(\frac{q_-}{\tilde{q}} \sin\left(bc \operatorname{arctan}\left(\frac{\tilde{q}}{r^{D-2}}\right) + \tilde{C}_1\right)\right)^2, \\ \chi(r) &= \frac{2}{bq_-} \left(\tilde{q} \cot\left(bc \operatorname{arctan}\left(\frac{\tilde{q}}{r^{D-2}}\right) + \tilde{C}_1\right) - q_3\right). \end{aligned} \quad (18)$$

The metric and curvature are well behaved over the range $0 < r < \infty$. However, the scalars can only be non-singular over the same range by an appropriate choice of \tilde{C}_1 provided that $bc < 2$. This can be seen as follows. The arctan varies over a range of $\pi/2$ when r goes from 0 to ∞ . It is multiplied by bc and thus the argument of the sine varies over a range of more than π if $bc > 2$. Therefore, for $bc > 2$ there is always a point r_c such that $\chi \rightarrow \infty$ as $r \rightarrow r_c$. Note that the breakdown of the solution occurs at weak string coupling: $e^\phi \rightarrow 0$ as $r \rightarrow r_c$. This singularity is not resolved upon uplifting and corresponds to a black hole with a naked singularity (in the case of Reissner-Nordström, $M^2 < Q^2$). The same holds for the limiting case of $bc = 2$. Therefore the case $q^2 < 0$ only yields regular instanton solutions for $bc < 2$, together with the condition that \tilde{C}_1 and $\tilde{C}_1 + bc\pi/2$ are on the same branch of the cotangent.

The metric in (18) has a Z_2 isometry corresponding to the reflection $r^{D-2} \rightarrow \tilde{q}r^{2-D}$ which interchanges the two asymptotically flat regions. This reflection has a fixed point, corresponding to the selfdual radius

$$r_{sd}^{D-2} = \tilde{q}. \tag{19}$$

Furthermore, the thickness of the neck was in [1] computed to be

$$\rho_{sd}^{D-2} = 2\tilde{q}. \tag{20}$$

We have summarised this in the following figure:

Fig. 1 The geometry of a wormhole. The two asymptotically flat regions at $r = 0$ and $r = \infty$ are connected via a neck with a minimal physical radius ρ_{sd} at the self-dual radius r_{sd} .

3 Instanton action

The value of the action, evaluated on the instanton solution, is a key ingredient in the semiclassical approximation of the euclidean path integral. In [1] we computed the instanton action for the three cases, corresponding to $q^2 > 0$, $q^2 = 0$, and $q^2 < 0$. This was done by specifying the additional surface term added to (4), which solely determines the instanton action. This surface term can be found from the dual description in terms of the $(D - 1)$ -form field strength formulation. We here summarise the results.

For the case when $q^2 \geq 0$, the contribution to the action coming from infinity is given by

$$\mathcal{S}_{inst}^\infty = \frac{4}{b^2} (D - 2) \text{Vol}(S^{D-1}) bc \left(\sqrt{q^2 + \frac{q_-^2}{g_s^b}} \right). \tag{21}$$

Here we have used the relation between C_1 and the asymptotic value of the dilaton, $g_s^b = (q_-/q)^2 \sinh^2 C_1$. Notice that the instanton action is proportional to the mass of the black hole to which the solution uplifts in one dimension higher. Furthermore, the result (21) also holds for $q^2 = 0$, which gives the lowest value

of the action. The resulting instanton action is then inversely proportional to $g_s^{b/2}$. The D-instanton of ten-dimensional IIB corresponds to taking $b = 2$. The extremal instantons for the universal hypermultiplet action (3) [3, 4] also fall into this class: the membrane instantons correspond to $b = 1$ whereas the NS-fivebrane instantons correspond² to $b = 2$. We have here given only the contribution from infinity. The non-extremal instantons also contribute to the action at the other boundary, where $r = r_c$. Since the solution is singular at this point, it is however not clear that the supergravity approximation is still valid in this region.

The case when $q^2 < 0$ is very different. For $bc < 2$, these are regular wormhole solutions with two asymptotic boundaries at $r = 0$ and $r = \infty$ that are related by a reflection symmetry. The wormhole action gets contributions from both these boundaries, and the result is

$$\mathcal{S}_{\text{wormhole}} = \frac{4}{b^2} (D - 2) \text{Vol}(S^{D-1}) b c \tilde{q} \left(\cot \tilde{C}_1 - \cot(\tilde{C}_1 + bc \frac{\pi}{2}) \right). \quad (22)$$

Due to the fact that \tilde{C}_1 and $\tilde{C}_1 + bc\pi/2$ are on the same branch of the cotangent, the total instanton action is manifestly positive definite. One can rewrite the above result in terms of the string coupling constant, using $g_s^{b/2} \equiv e^{b\phi_\infty/2} = (q_-/\tilde{q}) \sin \tilde{C}_1$. In the neighborhood of $bc \approx 2$, the instanton action becomes very large, and the limit to the critical point where $bc = 2$, it diverges. At that point, the wormhole solution is no longer regular.

4 Wormholes in string theory

We have seen that the condition for regular wormholes is that there exist models for which $bc < 2$. In type IIB in ten dimensions, this is not satisfied. Toroidal compactifications of string theory only lead to values of b for which $bc \geq 2$, so no wormholes exist for these cases. However, we have seen that for the universal hypermultiplet, which descends from a Calabi-Yau compactification of type II strings, one can have the value $b = 1$ in $D = 4$, and so $bc = \sqrt{3} < 2$. The solution is then characterized by the dilaton and the RR scalar φ that descends from the RR three-form gauge potential in IIA in ten dimensions. Since the extremal case $q^2 = 0$ corresponds to a wrapped type IIA euclidean membrane over a (supersymmetric) three-cycle, it is natural to suggest that the wormhole, with $q^2 < 0$, corresponds to a wrapped non-extremal euclidean D2 brane.

Acknowledgements It is a pleasure to thank Mathijs de Vroome for stimulating discussions.
