Clinical manifestations and diagnosis of RA and psoriatic arthritis: distinct and complex disease entities Part 2

PATRICIA MINNOCK, RGN, FFN RCSI, BSC, MSC, PHDADVANCED NURSE PRACTITIONER (RHEUMATOLOGY), RHEUMATOLOGY REHABILITATION, OUR LADY’S HOSPICE AND CARE SERVICES, HAROLD’S CROSS, DUBLIN

This update on inflammatory arthritis (IA) reviews the clinical manifestations and diagnosis of the separate disease entities of rheumatoid arthritis (RA) and psoriatic arthritis (PsA), multifactorial diseases with common and distinct features. RA is regarded as the index disease of the IA while PsA was originally seen as an atypical variant of RA before gaining its own unique identity.

Clinical signs of RA
The key signs of early IA joint disease in RA include swelling, tenderness, warmth, and painful movement; joint tenderness is the most sensitive physical sign. The joints most often involved early in the disease are the small joints of the hands and feet, commonly in symmetrical distribution, with gradual progression to the larger joints of the upper and lower limbs. Tendon sheath synovitis, predominately affecting the flexor tendon sheath of the hands, is another common finding. The degree of joint swelling evident may not correlate with the amount of active synovitis or pain expressed by the patient. Joint swelling may be peri-articular or intra-articular, the latter is associated with the presence of a joint effusion.

Articular features of RA
The usual pattern of joint distribution or involvement includes the proximal interphalangeal joints (PIP) and the metacarpophalangeal joints (MCP) joints of the hands, wrists, elbows, shoulders, knees, ankles, subtalar, and metatarsophalangeal (MTP) joints of the feet. The cervical spine is the only characteristic axial location, with atlantoaxial subluxation a known complication, and tempromandibular joints are frequently involved. The radiographic hallmarks of chronic synovitis include periarticular osteoporosis, focal bone erosions at the joint margins and loss of joint space. Inadequately treated articular inflammation can lead to progressive weakening or destruction of collateral structures, including the associated joint ligaments, tendons, cartilage,
and bone. In addition, the pain associated with ongoing synovitis frequently leads to decreased range of movement at the affected joints. Initially, it is inflammation, and subsequently the progressive joint destruction, evident on x-ray, that drives disability in RA. It is estimated that 90% of patients with RA become disabled within 20 years of disease onset. While the recognised classic presentation of RA is a symmetric polyarthritis of the small joint of the hands and feet it may also present with an extra-articular or non-articular presentation, such as a local bursitis, tenosynovitis, carpal tunnel syndrome, or a symmetric presentation with a diffuse polyarthralgia or polymyalgia.

**Extra-articular features of RA**

Extra-articular features of RA affect over 40% of patients, and involve multiple organ systems (Figure 1). One of the most common extra-articular manifestations is the development of subcutaneous rheumatoid nodules. This feature, found in about 30% of patients with RA, is usually associated with the presence of a high titre rheumatoid factor (RF) antibody. Rheumatoid nodules are regarded as a cardinal diagnostic feature, they have been shown to be a marker for more severe disease but often appear late in the disease. Studies show a two to fourfold increase in mortality in patients with extra-articular manifestations, such as rheumatoid nodules. Early presence of rheumatoid nodules is regarded as a predictor of more severe extra-articular manifestations. The many and varied extra-articular manifestations occur in a small but important subset of patients with RA 10 (Figure 1).

**Systemic extra-articular features of RA**

Systemic features of RA also referred to as constitutional or extra-articular manifestations, such as fatigue, fever, anorexia and weight loss, may occur early in the course of the disease. In some cases these features persist, and can predominate the articular symptoms. Elderly patients in particular may present with polymyalgias (pain in several muscle groups), polyarthralgias (pain in several joints simultaneously), and profound fatigue. Laboratory indicators of systemic involvement in RA include elevated acute-phase reactants; erythrocyte sedimentation count (ESR); C-reactive protein (CRP); anaemia; thrombocytopenia; elevation of certain liver function tests. These multi-system features found in a small but important subset of patients, are presented in Figure 1 and summarised in Table 1. When present these can confound the correct diagnosis of this disease that has no single diagnostic pathognomonic feature. (Table 1)

**Clinical signs of PsA**

Clinical signs of PsA are similar to those of RA. These key signs of an early inflammatory joint disease include swelling, tenderness, warmth, and painful movement. It is recognised that the associated joint tenderness found in PsA is less than that found with RA. Clinical signs peculiar to PsA include psoriasis, nail changes such as nail pitting – small indentations in the nail, and onycholysis (separation of the nail from the nail bed), tendonitis and dactylitis. The range of signs and symptoms can vary from patient to patient dependent on both the variety and severity of presentation.

**Articular features of PsA**

PsA is a heterogeneous condition; patients may present with any combination of diverse features at different stages of their disease. Five classic presentations of joint involvement are described (Table 2).

**Extra-articular features of PsA**

Any of these aforementioned presentations may be accompanied by the most frequently described extra-articular manifestations of psoriatic arthritis listed in Table 3. Unlike RA, PsA is not a multisystem disorder, the predominant extra-articular manifestations include, psoriasis, dactylitis, enthesitis and nail lesions.
LIcensed In:

- Rheumatoid arthritis
- Psoriatic arthritis
- Ankylosing spondylitis
- Plaque psoriasis
- Pediatric patients with juvenile idiopathic arthritis
- Pediatric patients with plaque psoriasis
Table 3: Extra articular and systemic features of PsA

1. Any form of psoriasis (or a personal or family history of psoriasis)
2. Dactylitis – sausage shaped digits (inflammation of a finger or toe)
3. Enthesitis: (inflammation of the entheses i.e the sites where tendons or ligaments insert into bone)
4. Tenosynovitis (tendon sheath inflammation)
5. Features common to the spondyloarthropathies: mucous membrane lesions, ocular lesions (conjunctivitis, iritis, uveitis), urethritis, colitis, aortic root dilatation, HLA-B27 association

It is noteworthy that fatigue is seldom listed as either an extra articular or systemic feature of PsA. More commonly it is referred to as a symptom or a comorbidity of this disease entity. Its recognition as an important feature of PsA is recent. It is acknowledged that fatigue is often underrated by treating physicians.

Diagnosing RA and PsA
Distinguishing a chronic illness such as RA from other self-limiting conditions can be difficult. There are no early onset disease specific features; the characteristic hallmarks of the disease develop over time. A salient characteristic of RA is its chronic and enduring nature; therefore it is not unusual that the diagnosis of RA is delayed for months or even years. With the lack of a disease-specific feature or test the diagnosis of RA remains a composite of clinical and investigational features.

The study of PsA has lagged behind other inflammatory arthropathies; it still lacks universal agreement on diagnostic criteria and therefore can pose a diagnostic challenge for physicians.

Laboratory investigations: markers of inflammation
Laboratory measures or markers of a biological activity within the body such as inflammation, that indirectly measure a disease state, are known as surrogate measures. Inflammation is a biological activity; in RA and PsA this is prolonged, and disproportional. Therefore, measures of inflammation, called acute-phase reactants, are used as surrogate markers of this inflammatory process. The most widely used biological markers to establish the presence of inflammation and disease activity in RA and PsA include laboratory blood measurement such as:
- an elevated ESR, CRP and fibrinogen; elevated liver enzymes, specifically serum aspartate aminotransferase (AST) and alkaline phosphatase; a fall in serum albumin level; anaemia of chronic disease, and hypoalbuminaemia.

Clinical diagnosis
There is no one clinical, radiological, or immunological feature that is pathognomonic of RA or PsA, therefore, the diagnosis is largely clinical, made by recognising the pattern of signs and symptoms. Diagnosis of an early IA is dependent on good history taking skills and physical examination rather than on any special investigations. The standard procedure for diagnosis includes documentation of history and pattern of

| MRI/Ultrasound abnormalities                                            | MRI/Ultrasound abnormalities              |

**Systemic features:** fatigue, fever, weight loss

---

Joint swelling and pain, physical examination, laboratory tests for measures of inflammation such as ESR and CRP; evidence of specific auto antibodies, such as RF and anti-cyclic citrullinated peptide (anti-CCP) antibodies; radiographic imaging of affected joints, and presence of extra-articular disease and co-morbid conditions.

The composite clinical and investigational features of RA summarised in Table 4, provide a framework for diagnosis, and for monitoring and management of the course of this chronic rheumatic autoimmune disease. A history indicative of RA includes prolonged early morning stiffness that improves with activity, polyarthritis, polyarthralgia (pain in many joints), and fatigue. Examination findings consistent with a diagnosis of RA include symmetric polyarthritis and rheumatoid nodules. Radiographic changes include periarticular osteopenia, joint space loss, and erosions. Although most serology studies are neither sensitive nor specific for RA they help exclude mimics of RA and confirm the presence of inflammation.

The standard procedure for diagnosing PsA includes documentation of history and pattern of articular and extra-articular features, physical examination, and laboratory testing to establish markers of inflammation, and serological status of RF. The majority of cases will be RF negative on serology (90-95%). The composite clinical and investigational features of PsA are summarised in Table 5. These provide a framework for diagnosis and for monitoring and management of the course of this distinct disease entity. Patients with PsA usually present with the typical hallmarks of an inflammatory arthritis; joint pain, swelling, erythema and varying degrees of joint stiffness, fatigue, impaired function, other defining features of this disease entity including enthesitis, dactylitis, psoriasis, nail changes, distal interphalangeal involvement, and iritis.

Subsequent review will provide an update management of these similar yet distinct disease entities.

---

**PRACTICE NURSES**

**Ranelagh * Barrow Street * Navan Road * Churchtown**

**Dublin 6 * Dublin 4 * Dublin 7 * Dublin 14**

We are currently seeking to recruit Practice Nurses on a fixed-term & permanent basis to support our dynamic and expanding GP practices in Dublin, North and South. We are also recruiting for Locum Nurses for our many GP Practice locations in Dublin.

- **Ranelagh Medical** – Fixed term Contract (3 days per week)
- **Barrow Medical & Churchtown Medical** – Fixed term Contract (2 days per week)
- **Phoenix Medical, Navan Road** – Permanent, part time (16 hours per week)

The successful candidate will enjoy an interesting & varied role providing clinical practice nursing, health promotion and health screening services. Previous practice nursing experience is desirable but not essential. The company is willing to facilitate additional specific training if required.

This is a fantastic opportunity for proven team-players who display a pro-active, can-do attitude. Please email your CV and cover letter to recruitment@centrichealth.ie or call us on 01 299 3500 for more information.

Apply with CV by Monday 11th February.
