Abstract: The 1,3-dipolar cycloaddition of a variety of aromatic and aliphatic nitrile oxides to 2,5-trans-2,5-diphenylypyrrolidine derived acrylamide and cinnamamide efficiently affords the corresponding 4,5-dihydroisoxazole-5-carboxamides in a highly regio- and stereoselective manner. The cycloaddition of aliphatic nitrile oxides to the analogue methacrylamide proceeds also smoothly to afford the expected cycloadducts in moderate yields and very high regio- and stereoselectivity. In sharp contrast, aromatic nitrile oxides react with the same amide to afford 5-methyl-4,5-dihydroisoxazole-5-carboxamides in higher yields but as near 1:1 mixtures of diastereoisomers. Acid hydrolysis of these products afforded enantiopure 4,5-dihydroisoxazole-5-carboxylic acids.

Key words: asymmetric synthesis, cycloadditions, heterocycles, nitrile oxides, isoxazolines

The 1,3-dipolar cycloaddition is a fundamental tool for the synthesis of a variety of five-membered heterocyclic compounds. As a case of particular relevance, the 1,3-dipolar cycloaddition of nitrile oxides to alkenes provides a straightforward route to the 4,5-dihydroisoxazole ring, a structural motif in some biologically active compounds and a useful synthetic intermediate for the synthesis of a variety of bifunctional building blocks and bioactive compounds. There are a number of methodologies available for the stereochemical control of the reaction, most of them based on the use of chiral auxiliaries. Though the selective Lewis acid activation of the dipolarophiles in the presence of nitrile oxides and the amine bases required for its synthesis is particularly difficult, some catalytic approaches have also been reported. Nevertheless, there are still limitations in most cases regarding substrate generality (in particular for aliphatic substrates), chemical yields, regioselectivity and/or stereoselectivity. We now wish to report the results collected by using 2,5-trans-2,5-diphenylypyrrolidine as a suitable auxiliary in the stereo- and regioselective 1,3-dipolar cycloadditions of α,β-unsaturated amides 1a-c with nitrile oxides.

The 2,5-trans-diphenylypyrrolidine, available in both enantiomeric forms from inexpensive starting materials, was chosen as a $C_2$-symmetric auxiliary in order to circumvent any consideration related to the conformational flexibility of rotation around the amide C–N bond. Additionally, the good diastereofacial differentiation observed in related contexts was also taken into account.

α,β-Unsaturated amides 1a and 1b, readily available by acylation of (S,S)-2,5-diphenylypyrrolidine with acryloyl and cinnamoyl chlorides under standard conditions, were made to react with several nitrile oxides, obtained in situ from hydroximoyl chlorides 2–8 in the usual way (Scheme 1). The reaction proceeded smoothly in all cases to give the expected adducts 9–21 in variable yields. The results collected in Table 1 indicate the generality of the method, illustrated by cycloadditions of both amides 1a and 1b to aromatic (2–4, entries 1–5) and aliphatic (5–8, entries 6–13) substrates. In addition to the excellent diastereoselectivities observed in the generation of the new stereogenic centers at C-4 and C-5, it is worth mentioning that only trans-cycloadducts 10, 13, 15, 17, 19, and 21 were observed from cinnamoyl enamide 1b, thereby excluding any epimerization of the products. Moreover, the reaction proved to be highly regioselective in all cases, a fact attributed to the repulsive steric interactions expected between the R group and the bulky 2,5-diphenylypyrrolidine moiety in the opposite regiosomer.

Scheme 1 1,3-Dipolar cycloaddition of α,β-unsaturated amides 1a,b.

The more challenging extension of this methodology for the synthesis of products bearing quaternary stereogenic centers at C-5 was also investigated by reacting substrates 2–5 and 8 with methacrylamide 1c as the dipolarophile (Scheme 2, Table 1, entries 14–18).

In this case, a different behavior for aliphatic and aromatic substrates was observed: the former (e.g., 5 or 8) reacted slowly to afford products 25 and 26 in moderate yields, but with complete regio- and diastereoselectivity (entries 17 and 18). In sharp contrast, aromatic substrates 2–4 react faster to afford cycloadducts 22–24 in higher yields and with high regioselectivity, but with negligible de (entries 14–16). A retro-cyclization path leading to a thermodynamically controlled product distribution was
experimentally discarded: pure (R)- and (S)-22 cycloadducts were heated separately under the reaction conditions without any perceptible epimerizations.

Reductive release of the chiral auxiliary by reagents such as LiEt₃BH (amide to alcohol)⁰ or the Schwartz reagent (amide to aldehyde)¹¹ failed in our case. Hydrolysis by HCl–AcOH, however, afforded the desired 4,5-dihydroisoxazole-5-carboxylic acids 27–30 (Scheme 3).

The absolute R,R configuration of the newly created stereogenic centers in cycloadduct 10 was determined by single-crystal X-ray diffraction analysis¹² (Figure 1), while that of (R)-27, (R)-30 and the parent cycloadducts (R)-9 and (R)-22 were deduced after comparison of the optical rotation of the former with literature data. Thus, compound (R)-27 had $[\alpha]_D^{20} = -194$ (c 0.5, MeOH) and this value was compared with reported data for (R)-27 (sample of ee = 68%: $[\alpha]_D^{20} = -116$)¹³ and (S)-27 (sample of ee = 60%: $[\alpha]_D^{20} = +67$ (c 0.4, CHCl₃))¹⁴ Additionally, compound (R)-30 had $[\alpha]_D^{20} = -131$ (c 0.14, MeOH) and the optical rotation was compared with reported data for (S)-30 (sample of ee = 75%: $[\alpha]_D^{20} = +109$).¹³ Assuming uniform reaction pathways for the cycloadditions of 2–8 to cinnamamide 1b and acrylamide 1a, the R configuration of 11, 12, 14, 16, 18, and 20 and the R,R configuration of 13, 15, 17, 19, and 21 were assigned by analogy with 9 and 10, respectively.

Table 1 1,3-Dipolar Cycloaddition of Nitrile Oxides 2–8 to Amides 1a–c: Synthesis of Isoxazolines 9–26 (continued)
The absolute configuration of (S)-23 was also determined by single-crystal X-ray diffraction\(^\text{15}\) (Figure 2), while those of (R)- and (S)-22 were assigned tentatively by analogy of their characterization data with (R)- and (S)-23.

The high inductions observed for the cycloadditions of nitrile oxides to 1a and 1b and the absolute configurations at C-4 and C-5 can be explained as the result of the shielding of the si face of the C=C double bond of the dipolarophile by the neighbour phenyl group in the pyrrolidine moiety in the preferred s-cis conformation (Figure 3). Such a difference is anticipated in view of the higher steric CH(β)–auxiliary interactions in the s-trans conformer.

Apparently, the high inductions and the absolute configurations of the products 25 and 26 of the cycloadditions of aliphatic nitrile oxides to 1c are also consistent with a similar analysis, but in this case the preference for the s-cis conformer is not clear in view of the similar steric interactions that arise from C(β)H2–auxiliary or CH3–auxiliary contacts in both rotamers.

The absolute configuration of (S)-23 was also determined by single-crystal X-ray diffraction\(^\text{15}\) (Figure 2), while those of (R)- and (S)-22 were assigned tentatively by analogy of their characterization data with (R)- and (S)-23.

Synthesis of Enantiopure 4,5-Dihydroisoxazole-5-carboxylic Acids

In conclusion, the excellent facial discrimination by the 2,5-diphenylpyrrolidine makes it a convenient auxiliary which very efficiently controls the stereochemical course of the cycloaddition reactions of amides, affording single diastereomers in practically all cases. A limited success was encountered in the extension of the methodology for the synthesis of cycloadducts containing stereogenic centers: the cycloadditions to methacrylamide were substrate-dependent and proceed with high selectivity for aliphatic substrates only.

Hydroximoyl chlorides and amides were synthesized according to literature procedures. Compound 1b was synthesized by acylation of (S,S)-2,5-diphenyl-pyrrolidine with cinnamoyl chloride under standard conditions: [α]D20 = 209.3 (c 0.73, CHCl3). 1H NMR (300 MHz, CDCl3): δ = 1.71 (dd, 1 H, J = 12.0 Hz, J = 5.7 Hz), 1.79 (dd, 1 H, J = 12.0 Hz, J = 5.7 Hz), 2.36 (m, 1 H), 2.50 (m, 1 H), 5.40 (d, 1 H, J = 8.1 Hz), 5.56 (d, 1 H, J = 8.1 Hz), 6.42 (d, 1 H, J = 15.3 Hz), 7.16–7.31 (m, 15 H), 7.49 (d, 1 H, J = 15.3 Hz). 13C NMR (75 MHz, CDCl3): δ = 30.0, 32.6, 61.7, 61.9, 118.7, 124.8, 128.0, 128.1, 128.4, 129, 134.6, 141.7, 142.4, 143.4, 164.8. MS (EI): m/z (rel. intensity) = 438 (14) [M]+, 188 (71), 91 (100). Anal. Calcd for C26H24N2O2: C, 79.42; H, 6.89; N, 6.39. Found: C, 79.52; H, 6.75; N, 6.05.

Synthesis of Compound 27
To a solution of 9 (395 mg, 1 mmol) in AcOH (4 mL) was added 6 N HCl (2 mL) and the mixture was stirred at 100 °C for 40 h. The mixture was then co-evaporated several times with toluene and the residue was purified by flash chromatography (30:1 EtOAc–AcOH) to afford 30 (62%) as a syrup: [α]D20 = 194 (c 0.45, MeOH) (lit.16 (80:20 SR mixture): [α]D20 = 67 (c 0.41, CHCl3)). 1H NMR (300 MHz, MeOD): δ = 3.58 (dd, 1 H, J = 17.1 Hz, J = 6.9 Hz), 3.71 (dd, 1 H, J = 17.1 Hz, J = 11.7 Hz), 5.13 (dd, 1 H, J = 11.4 Hz, J = 6.9 Hz), 7.36–7.65 (m, 5 H). 13C NMR (75 MHz, MeOD): δ = 39.9, 79.4, 128.0, 129.9, 130.1, 131.6, 157.9, 174.0. MS (EI): m/z (rel. intensity) = 191 (46) [M]+, 146 (100), 118 (71), 77 (93). Anal. Calcd for C26H24NO: C, 62.82; H, 4.74; N, 6.33. Found: C, 62.62; H, 4.92; N, 7.28.
