#### Abstract

The synthesis of tribenzotriquinacene 4 by a stepwise cyclization strategy involving phenyl-substituted diindan intermediates is discussed in detail. Based on the determination of the anti $(\alpha)$ stereochemistry of the previously known phenyldiindanone 8 by standard electron impact mass spectrometry as well as on synthetical evidence $(\mathbf{8} \rightarrow \mathbf{1 2} \rightarrow \mathbf{1 4})$, the conversion of 8 to the syn ( $\beta$ ) phenyl-substituted isomer 20 by means of dehydrogenation-rehydrogenation sequences has been achieved. In particular, the preparation of the isomeric diindenones 15 and 16 as key synthetic intermediates by thermal syn elimination of the corresponding phenylsulfinyl and phenylseleninyl ketones 22 and 25 is described and con-

trasted to a bromination/dehydrobromination approach adopted from a previous report. The synthesis is completed by reduction of 20 to diindanol 27 followed by cyclodehydration, giving 4 in $14-19 \%$ overall yield from 8 . Non-cyclizing dehydration of 27 and the isomeric diindanol 9 gives the $\Delta^{4 b, 9}$-diindene $\mathbf{3 0}$ as the most stable non-cyclized isomer of 4. The steric effect of the syn- or anti-oriented phenyl substituents on the preferred conformation of the diindan skeleton is deduced from the contrasting vicinal ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ spin coupling observed for the stereoisomers, e.g. the 9 -phenyldiindans 28 and 29.

In 1957 Baker, McOmie et al. ${ }^{[2]}$ reported on the synthesis of novel aromatic compounds bearing benzoanellated pentalenes as parent systems. Among these, 1,2:5,6-dibenzopentalene, now generally called indeno $[1,2-a]$ indene (1), represented a particularly interesting target system because of its relatively low stability ${ }^{[3]}$. While the synthesis of the fully unsaturated "diindene" $\mathbf{1}$ has never been achieved to date ${ }^{[3 b]}$, the $4 \mathrm{~b}, 9,9 \mathrm{a}, 10$-tetrahydro derivative 2 was prepared by Baker et al. ${ }^{[2]}$ and, in due course, by others performing independent approaches ${ }^{[4,5]}$. Baker et al. ${ }^{[2]}$ also reported on the synthesis of several 9,10 -substituted derivatives of type 3 , without, however, defining the stereochemistry of these compounds.

In the course of our studies on the synthesis and properties of centrically condensed, polycyclic indan hydrocarbons ("centropolyindans" ${ }^{[6]}$ ), the unsubstituted tribenzotriquinacene 4 represented a particularly challenging target. In contrast to the facile access to several derivatives bearing an alkyl substituent at C-10 (centro-alkylated tribenzotriquinacenes) ${ }^{[7]}$, we have developed a very short (threestep) yet low-yield synthesis of 4 only recently ${ }^{[4]}$ using a twofold cyclodehydration strategy of suitably substituted 2 -benzhydryl-1,3-indandiols ${ }^{[8,9]}$. Therefore, it appeared interesting to pursue synthetic pathways to 4 starting from the phenyl-substituted diindan precursors (e.g. 3) described by Baker et al. ${ }^{[2]}$ In particular, we envisaged a single cyclodehydration for the construction of the third indan unit. To this end, the orientation of the phenyl substituent at $\mathrm{C}-10$ had to be determined unambiguously and, as will be shown be-

4
low, a method for epimerization of this stereogenic center had to be developed. The synthesis of $\mathbf{4}$ and the remarkably high reactivity of this triply benzoanellated triquinacene towards strong bases both in solution and in the gas phase have been communicated recently ${ }^{[10]}$; in the present paper, we report in detail on the synthesis and the stereochemistry of 10 -phenyl-substituted "fuso"-diindans ${ }^{[6,11]}$ of type 3 and on the stepwise preparation of 4 .

## Stereochemistry of Baker's Diindans

The 10-phenyldiindanone 8 represents the first important synthetic intermediate of this work. According to the previous report ${ }^{[2]}, \mathbf{8}$ is prepared in three steps from cinnamic acid (5), benzene, and benzaldehyde (Scheme 1). We considerably improved this sequence, in particular by decreasing the amount of the catalyst used in the third step (see Experimental). Thus, the diindanone 8 is easily accessible now from $7^{[12]}$ on a $70-\mathrm{g}$ scale in yields of $82-89 \%$.

Scheme 1

As shown previously ${ }^{[2]}$, reduction of 8 with $\mathrm{LiAlH}_{4}$ or $\mathrm{Al}(\mathrm{O} i \mathrm{Pr})_{3}$ leads, with high selectivity, to either of two stereoisomeric alcohols (previously termed "isomer A" and "isomer B", respectively ${ }^{[2]}$. On the basis of spectroscopic and synthetic results, we identified these alcohols as the epimeric $9 \beta$-hydroxy-10 $\alpha$-phenyldiindan 9 and $9 \alpha$-hydroxy$10 \alpha$-phenyldiindan 10 and, as a consequence, the diindanone 8 as the $10 \alpha$-phenyl stereoisomer. Finally, and not surprisingly, the cis (i.e. $4 \alpha H, 9 \mathrm{a} \alpha H$ ) fusion of the two fivemembered rings in $8-10$, which had been already assumed by Baker et al. ${ }^{[2]}$, is unambiguously corroborated by these stereochemical assignments.

The first hints to the stereochemistry of the two alcohols 9 and 10 were obtained from their standard electron impact (EI) mass spectra (Figure 1, Table 1). The stereoisomer 9 formed by reduction with $\mathrm{LiAlH}_{4}$ exhibits, in contrast to 10, a distinctively fast elimination of water from the molecular ion. This is a typical feature of stereoisomers bearing a hydroxy group oriented sterically favorably in the vicinity of a relatively weak $\mathrm{C}-\mathrm{H}$ bond, such as those in the benzhydrylic $\mathrm{C}-10$ position of 9 and 10. Among the four possible diastereomers 9, 10 (Scheme 1) and 26 and 27 (see
below, Scheme 6) comprising the relatively rigid cis-bicyclo[3.3.0]octane (i.e., the fuso-diquinane) skeleton, only one, namely 9 , has the entropically favorable mutual 1,3-syn orientation of the $9-\mathrm{OH}$ group and the benzhydrylic "activated" $\mathrm{C}(10)-\mathrm{H}$ bond. In the case of $\mathbf{1 0}$ as well as of $\mathbf{2 6}$ and $\mathbf{2 7}$, loss of water should take place only by unfavorable syn-1,2 elimination or, more likely, after isomerization of the carbon skeleton, which, in general, cannot compete with regioselective 1,3- and 1,4-elimination of water ${ }^{[13-16]}$.

Figure 1. Mass spectra (EI, 70 eV ) of the stereoisomeric diindanols 9 and 10

The mass spectrometric assignment of the stereochemistry of 9 as $10 \alpha$-phenyl isomer allows us, without any doubt, to deduce the same "exo" orientation for the phenyl group at C-10 of $\mathbf{1 0}$ and of the precursor ketone $\mathbf{8}$. Of course, $\mathbf{8}$ has to be considered thermodynamically more stable than the stereoisomer 20 (Scheme 4) since the phenyl group is situated above the convex side of the diindan framework ${ }^{[17]}$. The stereochemistry of $\mathbf{8 - 1 0}$ is also corroborated by a

number of chemical transformations of $\mathbf{8}$, as will be shown below.

Noteworthily, standard ${ }^{1} \mathrm{H}$-NMR spectrometry of $\mathbf{8 - 1 0}$ (Table 2) does not allow an unambiguous stereochemical identification of the two alcohols, in spite of distinctly different coupling constants found for 9 and $\mathbf{1 0}$. Whereas the small coupling constant of one of the benzydrylic protons of 8 in fact suggests the $\alpha$ orientation of the phenyl group $\left({ }^{3} J_{9 \mathrm{a}, 10}=3.0 \mathrm{~Hz}\right)$, the two alcohols 9 and 10 do not exhibit a similar effect. Notably, the small coupling constant found for $10\left({ }^{3} J_{9,9 \mathrm{a}}=2.2 \mathrm{~Hz}\right)$ involves the carbinol proton $(9-\mathrm{H})$, not the benzhydrylic one. Obviously, as observed in general for cyclopentane derivatives ${ }^{[18]}$, the conformation and thus the vicinal ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling of the diquinane moiety of $\mathbf{8 - 1 0}$ is strongly affected by the substituents (Figure 1) ${ }^{[19,20]}$. For comparison, Table 2 comprises also the partial ${ }^{\prime} \mathrm{H}-\mathrm{NMR}$ spectra of the $10 \beta$-phenyl ketone 20 , the corresponding alcohol 27 as well as those of the two stereoisomeric 10-phenyldiindans 28 and 29. As will be shown below, all of the new $10 \beta$-phenyl ("syn") isomers 20, 27, and 29 in fact exhibit relatively large vicinal ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling constants, as expected.

Baker et al. also reported on various attempts to dehydrate the alcohols $\mathbf{9}$ and $\mathbf{1 0}$ in order to introduce additional double bonds into the diindan framework (cf. $\mathbf{1}$ ). It is remarkable that these authors already considered, as an "interesting possibility" ${ }^{[2]}$, the formation of tribenzotriquinacene 4 as a product of dehydration of these alcohols. On
the basis of infrared spectrometry (viz. the absence of out-of-plane resonances indicative of ortho-phenylene groups) of the dehydration products isolated in very low yields, the formation of 4 was excluded ${ }^{[2]}$. It is evident that, without the potential of modern organic mass spectrometry and NMR spectroscopy, it was impossible to draw stereochemical conclusions simply from the non-occurrence of 4 upon dehydration of 9 and $\mathbf{1 0}$. On the basis of the mass spectrometrical data presented here, however, it is clear that the $\alpha$ ("anti") orientation of the phenyl group at $\mathrm{C}-10$ is the reason for the lack of cyclization.

The stereochemical assignment of epimeric alcohols 9 and $\mathbf{1 0}$ corresponds to the expected kinetic (or thermodynamic) control operating during the reduction of 8 with $\mathrm{LiAlH}_{4}$ [or $\left.\mathrm{Al}(\mathrm{OiPr})_{3}\right]$. The steric shielding at the concave $(\beta)$ side of the diindan skeleton of $\mathbf{8}$ leads to the attack of the $\mathrm{AlH}_{4}^{-}$ion from the convex $(\alpha)$ side, in spite of the presence of the $10 \alpha$-phenyl group. Under equilibrium conditions, however, the hydride transfer occurs also from the concave side of the diindan skeleton of 8 , generating the thermodynamically favorable $9 \alpha$-alcohol $\mathbf{1 0}$.

Scheme 2

A further proof for the orientation of the $10 \alpha$-phenyl group in $\mathbf{8}$ was obtained from the course of the cyclodehydration of the 9 ad-benzyl derivative of $\mathbf{1 0}$, viz. 12. This diindanol is synthesized in good yields from 8 by benzylation to give 11, followed by reduction with $\mathrm{LiAlH}_{4}$ (Scheme 2). Treatment of $\mathbf{1 2}$ with the ion-exchange resin Amberlyst A15 in benzene at reflux temperature gives the cyclodehydrated product, difuso-triindan 14 , in $93 \%$ isolated yield. The formation of 10-benzyltribenzotriquinacene $\mathbf{1 3}$ from $\mathbf{1 2}$ does not occur, again in accordance with the $\alpha$ preorientation of the phenyl group at $\mathrm{C}-10$. In contrast, as has been shown recently ${ }^{[16]}$, the corresponding $10 \beta$-phenyl stereoisomer of 12 does undergo cyclodehydration to 13 with high selectivity (whereas the corresponding $10 \alpha$-phenyl isomer of 14 is not formed). Thus, the course of the cyclization $\mathbf{1 2} \rightarrow \mathbf{1 4}$ corroborates, in line with the mass spectrometric data of the
simpler alcohols, the $\alpha$ orientation of the 10 -phenyl group in 12 and hence in $8-11$.

According to two-dimensional ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (NOESY and COSY) experiments, the hydroxy group in $\mathbf{1 2}$ is oriented to the convex ( $\alpha$ ) side of the diindan skeleton. A strong NOE is observed for the carbinol proton signal ( $\delta_{9 \beta-\mathrm{H}}=5.17$ ) and that of the benzhydrylic proton oriented to the concave side of the diindan skeleton ( $\delta_{10 \beta-\mathrm{H}}=4.48$ ). Moreover, the mass spectrum of $\mathbf{1 2}$ exhibits only a moderate loss of water from the molecular ions ( $55 \%$ B, Table 1), in line with the behavior of the non-benzylated diindanol $\mathbf{1 0}$. These results suggest that, in contrast to the reduction of 8 , the presence of the 9 a $\alpha$-benzyl substituent adjacent to the $10 \alpha$-phenyl group suppresses the attack of the $\mathrm{AlH}_{4}^{-}$ion from the $\alpha$ side.

With the stereochemical results in hand, we pursued, on the basis of the previously reported ketone $\mathbf{8}^{[2]}$, the epimerization of the benzhydrylic center at C-10 to generate phenyldiindan derivatives that may eventually undergo cyclization to tribenzotriquinacene 4.

## Epimerization of Baker's Diindan Ketone 8

In the course of their attempts to introduce additional double bonds into the diindan framework of 2, Baker et al. ${ }^{[2]}$ generated, by bromination/dehydrobromination of $\mathbf{8}$, an $\alpha, \beta$-unsaturated ketone to which they assigned the structure of $\mathbf{1 5}$ (Scheme 3). The yields of the enone thus produced were rather low and not stated explicitly ${ }^{[21]}$. Nevertheless, for our purpose, the enone $\mathbf{1 5}$ promised to be a suitable substrate for the (apparent) inversion of the stereochemistry at C-10 of 8 .

Scheme 3

8

We expected that the strained double bond of 15 should selectively undergo catalytic rehydrogenation from the less hindered side because of the stereodifferentiating phenyl substituent at $\mathrm{C}-10$. Thus, provided that the catalyst would not cause competing epimerization at $\mathrm{C}-10$, inversion of the two centers of the diindan junction ( $\mathrm{C}-4 \mathrm{~b}-\mathrm{C}-10$ ) would give rise to an indirect flip of the phenyl group leading to the $\beta$ ("endo") orientation (Scheme 4). Reduction of the resulting $10 \beta$-phenyl ketone 20 to a corresponding alcohol followed by acid-catalyzed cyclodehydration should then furnish the title compound 4 . In fact, as will be shown below, this route proved to be successful. As an interesting facet, it has been found that the enone $\mathbf{1 6}$ is formed along with the originally inferred isomer 15. Fortunately, albeit not surprisingly, 16 undergoes the designed rehydrogenation to 20 as well (Scheme 4).

Scheme 4

15

20

Many attempts to reproduce the bromination/dehydrobromination, with at least moderate yields, on the originally reported or on enlarged scale were unsatisfactory. In every case the yields of the dehydro product were very low ( $<10 \%$ ). The mixture of compounds (with the starting ketone 8 as the major component) obtained after the first step contained minor amounts of a product to which we tentatively attribute the structure 17 (Scheme 3). Interestingly, however, subsequent elution of this mixture through alumina, as described earlier ${ }^{[2]}$, furnishes a mixture of two yellow compounds, as evident from thin layer chromatography, in an approximately $1: 1$ ratio. It is obvious on the basis of closely similar physical and chemical properties that the two yellow products have the structure 15 and 16. Extensive modification of the reaction conditions ${ }^{[22]}$ did not increase the combined yield of $\mathbf{1 5}$ and 16 beyond $15 \%$ (see Experimental), but the mixture of the isomeric $\alpha, \beta$-unsaturated
ketones was produced irrespective of the method and conditions used.

Interestingly, use of an excess of bromine gives rise to the formation of the ring-opened dibromo ketone 19 in ca. $30 \%$ yield (Scheme 3), which has been fully identified by mass and NMR spectrometry as well as, pinpointedly, by preparative addition of bromine to the enone 7. The formation of 19 suggests that at least a fraction of $\mathbf{8}$ undergoes a protolytic $\mathrm{C}-\mathrm{C}$ bond cleavage at the "non-bridgehead", benzhydrylic ring position generating the highly stabilized oxyallyl ion 18. Deprotonation of $\mathbf{1 8}$ to 7 followed by addition of bromine then gives $\mathbf{1 9}$. Hence, part of the drawbacks of Baker's bromination/dehydrobromination sequence may be traced to the lability of $\mathbf{8}$ against hydrobromic acid formed during the first step. Accordingly, in our hands, the highest yield ( $15 \%$ ) of $\mathbf{1 5} / \mathbf{1 6}$ is obtained by working with bromine/chloroform solutions (instead of highly diluted bromine vapors ${ }^{[2]}$ ) but in the presence of an excess of potassium carbonate.

Another unfavorable feature of the bromination/dehydrobromination approach is the extremely low solubility of the enones 15 and 16 in most organic solvents. Therefore, significantly enlarged runs are excluded, in particular in the dehydrobromination step. Due to the extremely low solubility, full characterization of $\mathbf{1 5}$ and $\mathbf{1 6}$ by NMR spectrometry has not been accomplished up to now. Chromatographic separation of $\mathbf{1 5}$ and $\mathbf{1 6}$ is hampered by the finding that these enones readily interconvert on silica gel. At present, only fractions enriched with $\mathbf{1 5}$ or $\mathbf{1 6}$ have been obtained by repeated digestion of the crude product mixture and recrystallization. Finally, dimers of $\mathbf{1 5 / 1 6}$ have been observed by field desorption mass spectrometry (FD-MS) in varying amounts as byproducts ${ }^{[23]}$. The identity of the two isomers of the mixture of $\mathbf{1 5}$ and $\mathbf{1 6}$, however, is confirmed by IR, ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR-spectrometry, combustion analysis and by EI mass spectrometry. Besides the base peak for the molecular ion with $m / z 294$, the $70-\mathrm{eV}$ standard mass spectrum exhibits a rather abundant $[\mathrm{M}-\mathrm{H}]^{+}$ion $(\mathrm{m} / \mathrm{z}$ $293,65 \%$ ) characteristic of styryl ketones ${ }^{[24]}$ (viz. 16) as well as an $[\mathrm{M}-(\mathrm{H}, \mathrm{CO})]^{+}$peak $(\mathrm{m} / \mathrm{z} 265,42 \%)$. As will be shown below, a further proof for the identity of $\mathbf{1 5 / 1 6}$ is provided by the hydrogenation of the enone mixture ${ }^{[25]}$.

Because of the low efficiency of the bromination/dehydrobromination approach, completely independent methods for the conversion of $\mathbf{8}$ to $\mathbf{1 5}$ and $\mathbf{1 6}$ have been elaborated. Attempts to dehydrogenate 8 with palladium chloride in tert-butyl alcohol ${ }^{[26]}$ failed. In contrast, the thermal syn elimination method to generate $\alpha, \beta$-unsaturated ketones ${ }^{[27,28]}$ via the corresponding 9a-phenylsulfinyl or $9 \mathrm{a}-$ phenylseleninyl derivatives of $\mathbf{8}$ proved to be successful. Both of these three-step sequences have been carried out on a large preparative scale.

As shown in Scheme 5, treatment of 8 with diisopropylamide/diphenyl disulfide or benzeneselenyl bromide leads to the bridgehead-substituted derivatives 21 and 24 , respectively, in good yields ${ }^{[29]}$. Subsequent oxidation with metachloroperbenzoic acid (MCPBA) yields the corresponding sulfoxide $\mathbf{2 2}$ or selenium oxide $\mathbf{2 5}$. MCPBA oxidation on a
large scale produces varying amounts of the sulfone 23 as a byproduct. The thermal decomposition of $\mathbf{2 2}$ (or mixtures of $\mathbf{2 2}$ and $\mathbf{2 3}$ ) as well as of $\mathbf{2 5}$ in toluene at reflux temperature furnishes a mixture of products which contains considerable amounts of the isomeric enones 15 and 16 . The crude product mixture is precipitated from the reaction mixture with petroleum ether. Repeated extraction of virtually dimeric byproducts with hot benzene gives a fine, yellowish powder which, according to TLC analysis, contains essentially $\mathbf{1 5}$ and $\mathbf{1 6}$. The product thus obtained shows chemical and physical properties identical with those of the enone mixture produced by the bromination/dehydrobromination technique.

In summary, the sequence $\mathbf{8} \rightarrow \mathbf{2 1} \rightarrow \mathbf{2 2} \rightarrow(\mathbf{1 5 / 1 6})$ turned out to be successful yet cumbersome. The purification of the enones obtained in this way is critical to sulfur-containing impurities that may hamper subsequent rehydrogenation. Nevertheless, in contrast to the bromination/dehydrobromination sequence, the sulfenylation route allows the synthesis of the mixture of $\mathbf{1 5}$ and $\mathbf{1 6}$ on a multigram scale. The alternative sequence via the phenylseleno compounds 24 and $\mathbf{2 5}$ does not offer decisive advantages.

Due to the extremely low solubility of $\mathbf{1 5}$ and $\mathbf{1 6}$, the catalytic hydrogenation of the enones at atmospheric pressure and room temperature has to be carried out in dioxane (Scheme 6). With both of the isomers, it takes place with high stereoselectivity from the less sterically hindered side of the diindan framework giving the $10 \beta$-("syn"-)phenyldiindanone 20. According to a ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis of the crude reaction mixture, the $10 \alpha$-phenyl isomer 8 is not formed at all during the hydrogenation process. Slightly prolongated hydrogenation leads to complete reduction of the keto function giving the phenyldiindan 29 (see below). The purification of the syn ketone $\mathbf{2 0}$ is also critical in that this product tends to form solvent-containing gels. The crude product is obtained from methanol solutions in $83 \%$ yield and with ca. $85 \%$ purity. Further purification by flash chromatography and twofold recrystallization from $n$-hexane/ chloroform yields 20 as analytically pure, colorless needles of m.p. $81^{\circ} \mathrm{C}$. As a characteristic feature of $\mathbf{2 0}$, the vicinal ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling is particularly large $\left({ }^{3} J_{9 \mathrm{a} \alpha, 10 \alpha}=11.7 \mathrm{~Hz}\right.$, Table 2).

Reduction of $\mathbf{2 0}$ with $\mathrm{LiAlH}_{4}$ in ether furnishes the corresponding alcohol 27 as a single stereoisomer (Scheme 6). The coupling constants in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of this product (Table 2) suggest the presence of a $9 \beta$-hydroxy group, as has been found for the alcohol 9 obtained from the epimeric $10 \alpha$-phenyl ketone 8 . This observation is not surprising with regard to the additional steric shielding of the concave side of the diindan framework by the $10 \beta$-phenyl substituent of $\mathbf{2 0}$, thus disfavoring the attack of the $\mathrm{AlH}_{4}^{-}$ion to a much greater extent than in the case of 8. Certainly, the $10 \beta$-phenyl diindanol 27 represents the thermodynamically least stable of the four possible diastereomeric alcohols. Therefore, we tried to synthesize the forth, $9 \alpha, 10 \beta$ diastereomer 26 (Scheme 6) by treatment of 20 with $\mathrm{Al}(\mathrm{OiPr})_{3}$ (cf. 10, Scheme 1). Unfortunately, and much to our surprise, 26 did not form at all. Obviously, hydride

Scheme 5

transfer to the concave ( $\beta$ ) side is completely suppressed under these conditions ${ }^{[30]}$.

Characteristic ${ }^{1} \mathrm{H}-\mathrm{NMR}$ signals of the diindanone 20 and the alcohol 27 are contrasted to those of the corresponding stereoisomers 8 and, respectively, 9 and 10, in Table 2. In accordance with the stereochemistry assigned, all of the three ${ }^{3} J$ coupling constants of the diquinane core of $\mathbf{2 0}$ and 27 are relatively large ( $\geqslant 7 \mathrm{~Hz}$ ). The mass spectrometric fragmentation of 27 (Table 1) is also in line with the stereochemistry. In spite of the lack of a favorably oriented "activated" $\mathrm{C}-\mathrm{H}$ bond, water loss from the molecular ions $\mathbf{2 7}{ }^{-+}$ gives rise to the base peak in the standard EI spectrum, but the molecular ion peak is still remarkably intense ( $57 \%$ B), reflecting the intramolecular rearrangement prior to the water loss.

## Tribenzotriquinacene and Related Hydrocarbons

According to the inverted configuration at $\mathrm{C}-10$, acidcatalyzed dehydration of $\mathbf{2 7}$ in benzene or toluene at reflux temperature gives the cyclized product, tribenzotriquinacene 4, in $55-60 \%$ yield (Scheme 6). The solubility of this hydrocarbon in organic solvents is extremely low; it readily crystallizes from the hot reaction mixture and is completely precipitated after cooling to room temperature. The chemical and physical properties of 4 are identical with those of the product obtained by twofold cyclodehydration of 2 -benzhydryl-1,3-indandiol ${ }^{[4]}$. Indeed, the IR spectrum of 4 exhibits the out-of-plane bands (appearing as a narrow doublet at $\tilde{v}=742$ and $750 \mathrm{~cm}^{-1}$ ) characteristic of the three ortho-phenylene groups ${ }^{[31,32]}$, which led Baker et al. ${ }^{[2]}$ to ex-
clude, correctly, the formation of 4 during their dehydration experiments.

Finally, some congeners of 4 are described (Scheme 7) which represent the parent hydrocarbons of the $10 \alpha$ - and

Figure 2. Conformational equilibrium of the diindan framework and predominant conformation of syn- and of anti-phenyl substituted diindans
$10 \beta$-phenyl-substituted diindans of type 3. As mentioned above, the $10 \beta$-phenyldiindan 29 is easily formed by catalytic hydrogenolysis of $\mathbf{2 0}$. Under medium-pressure conditions ( $3-4$ bar at room temp.), the reduction is completed within two hours without detectable epimerization at $\mathrm{C}-10$. The corresponding stereoisomer 28 is prepared under the same conditions from the $10 \alpha$-phenyldiindanone 8 and is identical with the hydrocarbon synthesized previously ${ }^{[2]}$ by Wolff-Kishner reduction. The two readily crystallizing diindans exhibit characteristic ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling constants (Table 2). Again in line with its stereochemistry, the spectrum of the $10 \beta$-phenyl isomer 29 exhibits only large vicinal spin coupling ( ${ }^{3} J \geqslant 7.6 \mathrm{~Hz}$ ). Interestingly, the $10 \alpha$ isomer 28 again shows both a large and a small vicinal ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling, viz. ${ }^{3} J_{9 \mathrm{ac}, 10 \mathrm{~b}}=7.1$ and ${ }^{3} J_{9 \beta, 9 \mathrm{a} \mathrm{\alpha}}=2.4 \mathrm{~Hz}$. A similar feature is found for the $9 \alpha$-diindanol $10\left({ }^{3} J_{9 \beta, 9 \mathrm{a} \mathrm{\alpha}}=2.2 \mathrm{~Hz}\right)$.

The pronounced differences of the ${ }^{3} J$ values may be understood by considering the directive influence of the bulky phenyl substituent at the diindan framework. Whereas in the parent system the two rotamers $\mathbf{2}^{\prime}$ and $\mathbf{2}^{\prime \prime}$ (Figure 2) are equivalent, the $\beta$-phenyl-substituted derivatives adopt predominantly the conformation shown in I, hence minimizing the steric repulsion at the concave side of the diindan framework. Notably, all of the diquinane dihedral angles $\nless(\mathrm{H}-\mathrm{C}-\mathrm{C}-\mathrm{H})$ in form I are in the range of $0-30$ or $150-180^{\circ}$. In contrast, the isomers bearing an $\alpha$ phenyl substituent preferentially exist as rotamers II, thus minimizing the (weak) interaction of the phenyl group with the hydrogen atoms at the convex side of the molecules. As a characteristic feature of form II, one of the dihedral angles (drawn in bold in Figure 2) is near $90^{\circ}$, as reflected by the small ${ }^{3} J$ value in 28 and $\mathbf{1 0}$. The $\beta$-phenyldiindanone

20 is likely to adopt a conformation similar to $\mathbf{I}$ as well, whereas that of the $\alpha$-phenyl isomer 8 should approach form II. Of course, the flattening of the diindan skeleton due to the carbonyl $\mathrm{sp}^{2}$ center gives rise to a decreased dihedral angle $\mathrm{H}-\mathrm{C}-\mathrm{C}-\mathrm{H}$ at $\mathrm{C}-9-\mathrm{C}-10$, in line with the particularly small ${ }^{3} J_{9 a-10}$ value found for 8 . Thus finally, the features of the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra of Baker's diindan derivatives - which their stereochemical ambiguities at the outset of our work - may be rationally traced to the distinctive conformational behavior of the diindan skeleton ${ }^{[17,20]}$.

Scheme 7

In the course of our unsuccessful attempts to prepare the elusive diastereomer 26, we studied the dehydration of the isomers 9 and 27 in dimethyl sulfoxide ${ }^{[33]}$, hoping to stereospecifically produce the isomeric olefins $\mathbf{3 1}$ and $\mathbf{3 3}$, respectively. Indeed, no cyclization occurs under these dehydration conditions as expected on the basis of previous findings ${ }^{[34]}$. However, instead of 31 and 33 a single diindene (m.p. $185^{\circ} \mathrm{C}$ ) is obtained in low yield, to which we ascribe the structure $\mathbf{3 0}$ on the basis of ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY measurements (see Experimental). Baker et al. ${ }^{[2]}$ already obtained, besides other dehydration products, a non-cyclized "anhydro" product with m.p. $179-180^{\circ} \mathrm{C}$ from both 9 and 10 in very low yield. The olefin $\mathbf{3 0}$ formed in the present study is probably identical with that reported by Baker. Curiously en-
ough, 30 - not 32, as postulated in our previous paper ${ }^{[4,35]}$ - is formed as the major side product of the synthesis of tribenzotriquinacene 4 by cyclodehydration of 2-benzhy-dryl-1,3-indandiol 34 (Scheme 8) ${ }^{[4]}$. As a bis-endocyclic, tetrasubstituted alkene, $\mathbf{3 0}$ should be the most stable isomer among $30-33$, in line with the high stability of the related $1,2,3,4,5,6$-hexahydropentalen ${ }^{[36,37]}$. Obviously, extremely mild dehydration conditions would be necessary to prevent the shift of the double bond in the hypothetical diindenes 31 and 33.

Scheme 8

8

4
In conclusion, a multistep synthesis of tribenzotriquinacene 4 based on readily available phenyl-substituted diindan precursors has been developed. Key step of the overall sequence is the (indirect) epimerization at C-10, bearing the phenyl group, to eventually achieve acid-catalyzed cyclodehydration of the formerly elusive "endo" diindan alcohol 27 to give 4. Although this route to 4 is notably more cumbersome than the route employing twofold cyclodehydration of 2-benzhydryl-1,3-indandiol $34{ }^{[4]}$, it offers an interesting and alternative synthetic access to more highly fused centropolyindans and their derivatives. The stereochemical and conformational analyses accompanying the synthetic efforts presented here shed some additional light on the peculiarities of 9,10 -substituted $4 \mathrm{~b}, 9,9 \mathrm{a}, 10$-tetrahydroindeno[1,2$a$ ]indenes ( $C_{s}$-centrodiindans).

Melting points (uncorrected): Büchi 512 and Electrothermal melting point apparatus. - IR: Perkin-Elmer 377. - UV: Beckman model 25. - 'H NMR: Bruker AM 300, Bruker WP 80; CDCl $_{3} /$ TMS. - ${ }^{13} \mathrm{C}$ NMR: Bruker AM 300 ( $J$-modulated spin-echo experiment); $\mathrm{CDCl}_{3} / \mathrm{TMS}$, if not stated otherwise. COSY and NOESY measurements Bruker AM 300 and Bruker AC 250 P. MS: Finnigan MAT 311 A, Finnigan MAT CH 5 DF, and VG Analytical Autospec (Figure 1); EI, 70 eV . - Combustion analyses: Perkin-Elmer 240 and LECO CHNS-932 Analysator. - MPLC: Kieselgel 60 (LiChroprep $30-65 \mu \mathrm{~m}$, Merck) with Besta E 100 and Besta UV 1. - TLC: Kieselgel 60 (F 254) on Al foil (Merck).
(4ba,9au)-9a,10-Dihydro-10a-phenylindeno[1,2-a ]inden-9(4bH)one ( 8 ) is synthesized by a three-step sequence starting from 5
(Scheme 1). It has been considerably improved in the third step, in particular, as compared to the receipt given in the literature ${ }^{[2]}$. 3-Phenyl-1-indanone ( $\mathbf{6}$ ) is allowed to react with benzaldehyde on a half-mol scale to give 2 -benzylidene-3-phenyl-1-indanone (7) in $97 \%$ yield. The crude 7 is dried in vacuo at $80^{\circ} \mathrm{C}$ and then recrystallized from ethanol/ethyl acetate (ca. 10:1); m.p. $156-157^{\circ} \mathrm{C}$ $\left(158^{\circ} \mathrm{C}^{[12]}\right)$. - To a mechanically stirred solution of $7(50.0 \mathrm{~g}, 169$ mmol ) in 1.2 l of dry benzene is added aluminium chloride ( 115 g , a fivefold molar excess only!) in small portions. The mixture is heated to reflux for 12 h , then allowed to cool to room temp., and then poured into ice water. The resulting suspension is extracted several times with benzene (if this solvent is to be recycled in subsequent runs), and the combined extracts are washed with aqueous $\mathrm{NaHCO}_{3}$ and dried with $\mathrm{MgSO}_{4}$. Evaporation of the solvent gives an oily, orange residue, which is redissolved in methanol/ethyl acetate (ca. 9:1). The solution is heated to reflux with ca. 10 g of charcoal for 20 min , filtered through a thin pad of silica gel and then allowed to cool to $4^{\circ} \mathrm{C}$ to give $\mathbf{8}$ as bright-yellow crystals $(41.0-44.5 \mathrm{~g}, 82-89 \%)$; m.p. $132-134^{\circ} \mathrm{C}\left(132^{\circ} \mathrm{C}^{[2]}\right)$. $-\operatorname{IR}(\mathrm{KBr}):$ $\tilde{\mathrm{v}}=3060 \mathrm{~cm}^{-1}, 3020,1705,1690,1610,1600,1585,775,760,755$, $745,700,685 .-{ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.79\left(\mathrm{~d},{ }^{3} \mathrm{~J}=7.6 \mathrm{~Hz}\right.$, $1 \mathrm{H}), 7.74\left(\mathrm{~d},{ }^{3} J=7.7 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.65\left(\mathrm{td},{ }^{3} J=7.5,{ }^{4} J=1.1 \mathrm{~Hz}\right.$, $1 \mathrm{H}), 7.52\left(\mathrm{~d},{ }^{3} J=7.6 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.39\left(\mathrm{t},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right)$, $7.15-7.35(\mathrm{~m}, 7 \mathrm{H}), 7.03\left(\mathrm{~d},{ }^{3} J=7.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 5.11\left(\mathrm{~d},{ }^{3} J_{4 \mathrm{~b} .9 \mathrm{a}}=\right.$ $7.1 \mathrm{~Hz}, 1 \mathrm{H}, 4 \mathrm{~b}-\mathrm{H}), 4.78\left(\mathrm{~d},{ }^{3} J_{10,9 \mathrm{a}}=3.0 \mathrm{~Hz}, 1 \mathrm{H}, 10-\mathrm{H}\right), 3.54(\mathrm{dd}$, $\left.{ }^{3} J_{9 \mathrm{a}, 4 \mathrm{~b}}=7.1,{ }^{3} J_{9 \mathrm{a} .10}=3.1 \mathrm{~Hz}, 1 \mathrm{H}, 9 \mathrm{a}-\mathrm{H}\right) .-{ }^{13} \mathrm{C}$ NMR $(75 \mathrm{MHz})$ : $\delta=207.0(\mathrm{~s}, \mathrm{C}=\mathrm{O}), 156.4(\mathrm{~s}), 145.7(\mathrm{~s}), 144.6(\mathrm{~s}), 143.0(\mathrm{~s}), 135.7$ (s), 135.4 (d), 128.8 (d), 128.1 (d), 128.0 (d), 127.7 (d), 126.6 (d), 126.3 (d), 125.7 (d), 124.5 (d), 61.5 (d), 52.7 (d), 50.2 (d). - MS, $m / z(\%): 296(100)\left[\mathrm{M}^{\bullet+}\right], 295(23), 279(16), 278$ (15), 268 (12), 267 (18), 265 (22), 263 (9), 252 (18), 239 (10), 219 (20), 218 (36), 194 (14), 191 (24), 189 (45), 165 (31).
(4ba,9aa)-4b,9,9a,10-Tetrahydro-10a-phenylindeno[1,2-a]inden$9 \beta-o l(9$, Baker's isomer A) is prepared as described by Baker et al. ${ }^{[2]}$ by reduction of 8 with $\mathrm{LiAlH}_{4}$. (4ba,9aa)-9a,10-Dihydro-10a-phenyl-9a-(phenylthio) indeno[1,2-ajinden-9 (4bH)-one (21): A reaction apparatus assembled from predried glassware and equipped with a rubber septum is flushed with dry nitrogen. After introduction of 100 ml of dry tetrahydrofuran and $15.0 \mathrm{ml}(110 \mathrm{mmol})$ of freshly distilled diisopropylamine, the resulting solution is cooled to $-60^{\circ} \mathrm{C}$ by means of dry ice/ acetone. Within $30 \mathrm{~min}, 80 \mathrm{ml}$ of a 1.5 m solution of $n$-butyllithium $(120 \mathrm{mmol})$ in $n$-hexane is added through the septum. The mixture is stirred and allowed to warm to $0^{\circ} \mathrm{C}$. The stirred solution of lithium diisopropylamide thus prepared is recooled to $-45^{\circ} \mathrm{C}$, and a solution of $8(30.0 \mathrm{~g}, 101 \mathrm{mmol})$ in 150 ml of dry tetrahydrofuran is added through the septum within 40 min . Stirring is continued while the mixture is allowed to warm to $0^{\circ} \mathrm{C}$ within 1 h , its color turning from yellow to dark brown. While the temperature is being maintained by using an ice/water bath, a solution of $24.0 \mathrm{~g}(110$ mmol ) of diphenyl disulfide in 75 ml of dry tetrahydrofuran is injected within 20 min . Finally, the mixture is allowed to warm to room temp. and then stirred for further 1.5 h . The green solution is poured on 100 ml of a mixture of diluted hydrochloric acid and tetrahydrofuran (ca. 10:1). The organic layer is washed with diluted hydrochloric acid, turning orange, and then twice with saturated aqueous $\mathrm{NaHCO}_{3}$, water, and dried with sodium sulfate. Evaporation of the solvent gives a solid residue, which is recrystallized from petroleum ether/ethyl acetate yielding 21 ( $32.0 \mathrm{~g}, 78 \%$ ) as a colorless crystalline powder; m.p. $171-172^{\circ} \mathrm{C} .-\mathrm{IR}(\mathrm{KBr}): \tilde{\mathrm{v}}=$ $3045 \mathrm{~cm}^{-1}, 3025,3000,2900,1700,1590,770,755,745,740,695$, $690,660,610 .-{ }^{1} \mathrm{H}$ NMR ( 80 MHz ): $\delta=6.8-7.65(\mathrm{~m}, 18 \mathrm{H}), 4.97$ $\left(\mathrm{s}, 2 \mathrm{H}, 2 \mathrm{CHAr}_{2}\right) .-{ }^{13} \mathrm{C} \operatorname{NMR}(75 \mathrm{MHz}): \delta=204.1(\mathrm{~s}, \mathrm{C}=\mathrm{O})$, 153.8 (s), 143.9 (s), 142.3 (s), 140.0 (s), 136.1 (d), 135.2 (d), 134.8 (s), 130.5 (d), 128.8 (d), 128.26 (d), 128.16 (d), 127.99 (d), 127.86

This reaction is performed in batches up to the $60-\mathrm{g}$ scale of 21 . Varying effective amounts of MCPBA are used, which occasionally requires the addition of supplementary reagent to complete the oxidation. In most cases, the formation of a byproduct, viz. sulfone 23 (see below), is observed. The combined yields of $\mathbf{2 2}$ and $\mathbf{2 3}$ have been found to be as high as $94 \%$. The sulfone is separated upon the recrystallization of $\mathbf{2 2}$ described above. Advantageously, however, the sulfoxide $\mathbf{2 2}$ containing up to $10 \%$ of 23 can be employed in the thermal elimination to form the enones 15 and 16.
(4ba,9aa)-9a,10-Dihydro-10a-phenyl-9a-(phenylsulfonyl) indeno-[1,2-a]inden-9(4bH)-one (23): From the oxidation $21 \rightarrow 22$ described above, varying amounts of a material of low solubility in petroleum ether/ethyl acetate may be isolated. Recrystallization from ethyl acetate/tetrahydrofuran (ca. 3:2) gives colorless crystals which are identified as the sulfone 23; m.p. $207^{\circ} \mathrm{C}$ (dec.). - IR $(\mathrm{KBr}): \tilde{\mathrm{v}}=3062 \mathrm{~cm}^{-1}, 3023,2920,1703,1604,1454,1443,1286$, 1265, 1247, 1194, 1181, 1084, 1032, 938, 757, 724, 696, 617. $-{ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.25-7.40(\mathrm{~m}, 11 \mathrm{H}), 7.10-7.20(\mathrm{~m}, 2 \mathrm{H})$, $7.00-7.10(\mathrm{~m}, 5 \mathrm{H}), 5.31\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 4.82\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right)$. ${ }^{13} \mathrm{C}$ NMR ( 75 MHz ): $\delta=197.6$ ( $\mathrm{s}, \mathrm{C}=\mathrm{O}$ ), 153.2 (s), 144.1 (s), 141.3 (s), 139.6 (s), 139.4 (s), 136.2 (s), 134.8 (d), 131.5 (d), 130.6 (d), 128.5 (d), 128.4 (d), 128.2 (d), 128.0 (d), 127.8 (d), 127.7 (d), 126.2 (d), 125.5 (d), 124.4 (d), 124.2 (d), 82.3 (s, $9 \mathrm{a}-\mathrm{C}), 54.5$ (d), 51.7 (d). - MS, $m / z(\%): 436(\approx 0.5)\left[\mathrm{M}^{++}\right], 295(100)\left[\mathrm{M}^{++}-\mathrm{PhSO}_{2}\right], 294$ (18), 265 (30), 263 (11), 252 (11), 239 (5), 218 (17), 217 (18), 193 (5), 189 (14), 165 (8), 125 (7), 97 (5). This compound has been found to decompose readily on standing; satisfying combustion analytical data have not been obtained; exact mass measurements give: calcd. 436.1133; found 436.1180.
(4ba,9aa)-9a, 10-Dihydro-10a-phenyl-9a-(phenylseleno) indeno-[1,2-a ]inden-9(4bH)-one (24): A solution of lithium diisopropylamide ( 11.0 mmol ) in tetrahydrofuran is prepared as described above. The solution is stirred and cooled to $-40^{\circ} \mathrm{C}$, and a solution
of $8(2.96 \mathrm{~g}, 10.0 \mathrm{mmol})$ in 10 ml of dry tetrahydrofuran is added through the rubber septum within 10 min . After stirring at $-40^{\circ} \mathrm{C}$ for 30 min , a solution of $2.36 \mathrm{~g}(11.0 \mathrm{mmol})$ of benzeneselenyl bromide in 10 ml of tetrahydrofuran is added. The mixture is stirred for another 30 min and then poured on 50 ml of 0.5 N aqueous HCl and 50 ml of diethyl ether. The aqueous layer is extracted with diethyl ether, and the combined organic solutions are washed with aqueous $\mathrm{NaHCO}_{3}$ and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvents are evaporated to give a red-brown oily residue which is crystallized from petroleum ether/ethyl acetate to yield $24(2.90 \mathrm{~g}, 64 \%)$ as pale-pink crystals; m.p. $169-170^{\circ} \mathrm{C}$. - IR ( KBr ): $\tilde{\mathrm{v}}=3040$ $\mathrm{cm}^{-1}, 3000,2900,1695,1590,780,760,752,734,720,695,686$, $610 .{ }^{1}{ }^{1} \mathrm{H}$ NMR $(80 \mathrm{MHz}): \delta=6.75-7.8(\mathrm{~m}, 18 \mathrm{H}), 5.06(\mathrm{~s}, 1 \mathrm{H}$, $\mathrm{CHAr}_{2}$ ), $5.00\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right) .-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ): $\delta=204.7$ ( $\mathrm{s}, \mathrm{C}=\mathrm{O}$ ), 154.0 ( s$), 143.9$ (s), 142.8 (s), 141.3 (s), 137.4 (d), 134.9 (d), 135.2 (s), 130.0 (d), 128.8 (d), 128.27 (d), 128.10 (d), 128.03 (d), 127.87 (d), 127.79 (d), 127.50 (d), 126.2 (d), 124.58 (d), 123.90 (d), 66.7 (s, C-9a), 59.7 (d, $\mathrm{CHAr}_{2}$ ), 55.4 (d, $\mathrm{CHAr}_{2}$ ). $-\mathrm{MS}, m / z$ (\%): 452 (7) [ [ $\left.\left.{ }^{80} \mathrm{Se}\right] \mathrm{M}^{++}\right], 295$ (100) [M $\mathrm{M}^{++}$- PhSe], 294 (47), 293 (17), 280 (24), 279 (22), 278 (12), 267 (14), 265 (23), 252 (14), 219 (18), 218 (19), 191 (14), 189 (27), 165 (17), 157 (12) $\left[\mathrm{Ph}^{80} \mathrm{Se}^{+}\right] .-$ $\mathrm{C}_{28} \mathrm{H}_{20} \mathrm{OSe}$ (451.4): calcd. (4ba,9aa)-9a,10-Dihydro-10a-phenyl-9a-(phenylseleninyl) indeno-[1,2-a]inden-9(4bH)-one (25): A solution of $24(1.00 \mathrm{~g}, 2.21 \mathrm{mmol})$ in 30 ml of distilled dichloromethane is stirred and cooled to $-30^{\circ} \mathrm{C}$ unter nitrogen, and a solution of 520 mg of meta-chloroperbenzoic acid ( 2.4 mmol ; Janssen, purity $80 \%$ ) in the same solvent is added. The mixture is allowed to warm to room temp. and is then stirred for further $10 \mathrm{~h}\left[\mathrm{TLC}\right.$ control $\left.\left(\mathrm{CHCl}_{3}\right)\right]$. It is then poured on 50 ml of diethyl ether and 50 ml of aqueous $\mathrm{Na}_{2} \mathrm{SO}_{3}(10 \%)$. The aqueous layer is extracted with diethyl ether, and the combined organic solutions are washed with $\mathrm{NaHCO}_{3}$ and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvents are removed in vacuo at room temp. to prevent decomposition of the product, and the oily residue is subjected to liquid chromatography $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ to give $25(0.48 \mathrm{~g}, 46 \%)$ as yel-low-orange crystals; m.p. $138^{\circ} \mathrm{C}$. $-\mathrm{IR}(\mathrm{KBr}): \tilde{\mathrm{v}}=3040 \mathrm{~cm}^{-1}$, 3010, 1675, 1585, 938, 780, 760, 752, 738, 730, 700. - ${ }^{1} \mathrm{H}$ NMR $(300 \mathrm{MHz}): \delta=7.8-7.95(\mathrm{~m}, 2 \mathrm{H}), 7.15-7.6(\mathrm{~m}, 16 \mathrm{H}), 4.95(\mathrm{~s}$, 2H, $2 \mathrm{CHAr}_{2}$ ). - MS, $m / z(\%): 294$ (100) [ $\left.\mathrm{M}^{\bullet+}-\mathrm{PhSeO}\right], 293$ (22), 265 (70), 263 (41), 239 (11), 189 (12), 187 (10), 163 (5), 147 (8), 133 (16), 132 (25). This compound has been found to decompose readily on standing; satisfying combustion analytical data have not been obtained.

10-Phenylindeno [1,2-a]inden-9(10H)-one and 10-Phenylindeno-[1,2-a]inden-9(4bH)-one (as a mixture, 15 and 16)
a) The method described previously ${ }^{[2]}$ using bromine vapors in dry air (or nitrogen) has been modified in various ways. In our laboratory, the best results have been obtained as follows: A stream of dry nitrogen is slowly bubbled through a solution of $0.30 \mathrm{ml}(5.9$ mmol ) of bromine in 200 ml of dry chloroform (Merck, p.a.) and then through a solution of $8(3.00 \mathrm{~g}, 10.0 \mathrm{mmol})$ in 170 ml of the same solvent. The stream is maintained for a total of 95 h while the progress of the reaction is followed by $\operatorname{TLC}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$, and additional bromine ( $4 \times 0.2 \mathrm{ml}$ ) in chloroform is used. The yellow solution is concentrated to a small volume, and 15 ml of diethyl ether is added. A crystalline product may precipitate but is redissolved by addition of some tetrahydrofuran, and the solution is eluted twice through alumina (diethyl ether as eluent). After concentration of the combined eluates to a volume of ca. 40 ml , the solution is kept at $0-5^{\circ} \mathrm{C}$ to give a mixture of $\mathbf{1 5 / 1 6}$ as yellow crystals ( $0.25 \mathrm{~g}, 8.4 \%$ ), m.p. $265-273^{\circ} \mathrm{C}$ (dec.).
b) An upscaled procedure omitting the tedious use of bromine vapors is given in the following: To a solution of $5.0 \mathrm{~g}(17.0 \mathrm{mmol})$
of 8 in 200 ml of chloroform (Merck, p.a.) is added 120 g of finely powdered, dry potassium carbonate. The suspension is vigorously stirred, and a solution of bromine ( $3.5 \mathrm{ml}, 69 \mathrm{mmol}$ ) in 200 ml of chloroform (p.a.) is added within 5 h . The color of the solution turns yellow-orange and should be maintained throughout the addition. After stirring overnight, the suspension is filtered, and the salts are washed with chloroform. The lemon-yellow solution is concentrated to a volume of 10 ml and, after dilution with 40 ml of diethyl ether, is eluted through neutral alumina (act. grade $I / 90$, $10-15 \%$ water, column $2 \cdot 30 \mathrm{~cm}$ ) with diethyl ether. The resulting eluate is concentrated to ca. 75 ml and kept at $0-5^{\circ} \mathrm{C}$ for 3 d . The fine, yellow precipitate is collected, representing a mixture [TLC $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}, R_{\mathrm{f}}=0.16\right.$ and 0.18$]$ of 15 and $16(0.5 \mathrm{~g}, 10 \%)$ as a brightyellow powder, m.p. $260-278^{\circ} \mathrm{C}$ (dec.). The mother liquor is eluted through alumina for another time to give a further crop of $\mathbf{1 6 / 1 7}$ ( 0.25 g ; total yield $15 \%$ ).
c) Thermal syn Elimination with 22: The procedure described in the following has been upscaled to $50-\mathrm{g}$ batches with similar results. A mixture of $16.0 \mathrm{~g}(38.1 \mathrm{mmol})$ of 22 and 600 ml of freshly distilled toluene is heated to reflux for 4 d . The initally clear, orange solution turns yellow within some hours, and the course of the reaction is followed by TLC $\left(\mathrm{CHCl}_{3}\right)$. The solvent is evaporated to give an orange-red, oily residue which is redissolved with ca. 90 ml of chloroform, and petroleum ether ( ca .400 ml ) is added in small portions to precipitate a fine-crystalline, yellow material. The mixture is cooled to $0-5^{\circ} \mathrm{C}$ for 3 h , and the precipitate is then filtered by suction, washed with some petroleum ether, and dried to give a yellow powder ( 8.2 g ). TLC analysis $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ or $\left.\mathrm{CHCl}_{3}\right)$ of this material shows two yellow components ( $R_{\mathrm{f}} \approx 0.1$ and 0.15 ) and an orange, less polar component. The mixture is digested several times with benzene to remove the orange, less polar component, giving a mixture of 15 and 16 as lemon-yellow crystals ( $5.8 \mathrm{~g}, 52 \%$ ); m.p. $267-268^{\circ} \mathrm{C}$ (dec.). Baker et al. ${ }^{[2]}$ reported m.p. $266-269^{\circ} \mathrm{C}$. Repeated recrystallization of this mixture from benzene or toluene gives a yellow material containing almost exclusively the slowly eluting component ( $R_{\mathrm{f}} \approx 0.18, \mathrm{CHCl}_{3}$ ); m.p. $281-282^{\circ} \mathrm{C}$ (dec.), which is poorly soluble in hot toluene. Workup of the mother liquors gives a yellow material containing almost exclusively the faster eluting compound ( $R_{\mathrm{f}} \approx 0.27, \mathrm{CHCl}_{3}$ ); m.p. $236-240^{\circ} \mathrm{C}$ (decomp.). The $15 / 16$ mixture may also be recrystallized from dichloromethane; both components undergo hydrogenation to $\mathbf{2 0}$. Liquid column chromatography ( $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{Kieselgel} 60$; Merck) of the mixture obtained after digestion of the crude precipitate with benzene also allows removal of all byproducts; a separation of $\mathbf{1 5}$ and 16, however, is not achieved.
d) Thermal syn Elimination with 23: In a way analogous to that described above for 22, a mixture of 15 and 16 is obtained by heating $3.0 \mathrm{~g}(6.9 \mathrm{mmol})$ of 23 in 100 ml of toluene. However, the reaction requires $6-7 \mathrm{~d}$ to be completed, yielding $15 / 16$ ( 750 mg , $37 \%$ ).
e) Thermal syn Elimination with 25: In an analogous procedure, the selenium oxide $25(32.2 \mathrm{~g}, 68.9 \mathrm{mmol})$ is heated in 1.5 l of toluene for 7 d . Precipitation of the crude product mixture with petroleum ether followed by digestion with benzene gives a mixture of 15 and $16(8.0 \mathrm{~g}, 39 \%)$; m.p. $281-282^{\circ} \mathrm{C}$. $-\operatorname{IR}(\mathrm{KBr}): \tilde{v}=3063$ $\mathrm{cm}^{-1}, 1692(\mathrm{C}=\mathrm{O}), 1602,1589,1556,1490,1463,1443,778,746$ (s), 736 (s), $703(\mathrm{~s}), 695(\mathrm{~s}), 662,632,614 .-{ }^{1} \mathrm{H}$ NMR ( 300 MHz , $\left.\mathrm{CDCl}_{2} \mathrm{CDCl}_{2}\right): \delta=8.23\left(\mathrm{~d},{ }^{3} J=7.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 8.11\left(\mathrm{~d},{ }^{3} J=7.6\right.$ $\mathrm{Hz}, 1 \mathrm{H}), 7.73\left(\mathrm{td},{ }^{3} J=7.5,{ }^{4} J=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right) 7.17-7.7(\mathrm{~m}, \mathrm{ca}$. 20 H ), 7.12 (quasi-t, ${ }^{3} J=7.8 \mathrm{~Hz}, 3 \mathrm{H}$ ). $-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ): $\delta=183.7$ and $183.4(\mathrm{~s}, \mathrm{C}=\mathrm{O}), 151.0$ and $150.1\left(\mathrm{~s}, \mathrm{C}^{\left.\mathrm{Ar}^{-}-\mathrm{CO}\right), 147.7}\right.$ (s), 146.0 (s), 145.5 (s), 144.7 (s), 144.4 (s), 144.2 (s), 143.3 (s), 143.0

C 89.77 , H 4.79; found C 88.99 , H 4.93.

2-Bromo-2-(a-bromobenzyl)-2,3-dihydro-3-phenyl-1H-inden-1one (19)
a) By Treatment of $\mathbf{8}$ with an Excess of Bromine Vapor: A slow steam of dry nitrogen is bubbled through a solution of 0.2 ml ( 7.7 mmol ) of bromine in 70 ml of chloroform (p.a.) and then through a solution of $1.00 \mathrm{~g}(3.37 \mathrm{mmol})$ of 8 in 70 ml of the same solvent. After 14 h , the color of the reagent solution has vanished almost completely. The reaction mixture is concentrated to dryness, and the residue is subjected to chromatography (Kieselgel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) to give ca. $0.6 \mathrm{~g}(60 \%)$ of the starting material and a second fraction, which is recrystallized from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /ethanol to give $19(100 \mathrm{mg}$, $6 \%$ ) as colorless crystals; m.p. $134-138^{\circ} \mathrm{C}$ (decomp.).
b) By Addition of Bromine to 7: To a stirred suspension of 2.96 $\mathrm{g}(10.0 \mathrm{mmol})$ of 7 in 75 ml of dry tetrachloromethane is added $1.60 \mathrm{~g}(10.0 \mathrm{mmol})$ of bromine in 25 ml of the same solvent within 1 h , and stirring is continued overnight to give a clear solution. Evaporation of the solvent and twofold recrystallization from petroleum ether/ethyl acetate give the dibromo adduct $19(3.70 \mathrm{~g}$, $81 \%$ ) as large, colorless crystals; m.p. $141-147^{\circ} \mathrm{C}$ (dec.). - IR $(\mathrm{KBr}): \tilde{v}=3090 \mathrm{~cm}^{-1}, 3064,3035,2967,2897,1719(\mathrm{C}=\mathrm{O}), 1604$, $1493,1462,1448,1288,1277,1262,1211,1150,1024,1014,756$ (s), $702(\mathrm{~s}) .-{ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.95\left(\mathrm{~d},{ }^{3} J=7.7 \mathrm{~Hz}, 1 \mathrm{H}\right)$, $7.74\left(\mathrm{dd},{ }^{3} J=7.5,{ }^{4} J=1.8 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.64\left(\mathrm{td},{ }^{3} J=7.5,{ }^{4} J=1.2\right.$ $\mathrm{Hz}, 1 \mathrm{H}), 7.48\left(\mathrm{t},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.32-7.40(\mathrm{~m}, 3 \mathrm{H}), 7.20(\mathrm{~d}$, $\left.{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.06-7.14(\mathrm{~m}, 3 \mathrm{H}), 6.78\left(\mathrm{dd},{ }^{3} J=7.8,{ }^{4} J \approx 1.7\right.$ $\mathrm{Hz}, 2 \mathrm{H}), 5.87(\mathrm{~s}, 1 \mathrm{H}), 5.50(\mathrm{~s}, 1 \mathrm{H}) .-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ): $\delta=$ 198.6 (s, $\mathrm{C}=\mathrm{O}$ ), 154.4 ( s$), 140.5$ (s), 136.3 (d), 135.7 (s), 133.4 (s), 130.8 (d), 129.1 (d), 128.7 (d), 127.80 (d), 127.51 (d), 127.38 (d), 127.1 (d), 124.9 (d), 72.6 (s, C-2), 57.0 (d), 51.0 (d). $-\mathrm{MS}, m / z$ (\%): 454/456/458 (0.3/0.6/0.3) [ $\left.\mathrm{M}^{\bullet+}\right], 375 / 377(30 / 30)\left[\mathrm{M}^{\bullet+}-\mathrm{Br}\right]$, 296 (83) [ $\left.\mathrm{M}^{\bullet+}-2 \mathrm{Br}\right], 295(100)\left[\mathrm{M}^{\bullet+}-(\mathrm{Br}, \mathrm{HBr})\right], 279(10), 268$ (20), 267 (25), 265 (27), 252 (19), 239 (7), 219 (15), 218 (22), 217 (9), 191 (19), 189 (30), 169/171 (14/14) [C7 $\left.\mathrm{H}_{6} \mathrm{Br}^{+}\right], 165$ (27). $\mathrm{C}_{22} \mathrm{H}_{16} \mathrm{Br}_{2} \mathrm{O}$ (456.2): calcd. (4ba,9aa)-9a,I0-Dihydro-10ß-phenylindenof1,2-a Iinden-9(4bH)one (20): A suspension of 1.5 g of palladium-on-charcoal $(10 \%$, Merck) in 450 ml of dioxane (freshly distilled from $\mathrm{LiAlH}_{4}$ ) is shaken under hydrogen in a hydrogenation apparatus for 2 h (ca. 50 ml of $\mathrm{H}_{2}$ being absorbed). After flushing with inert gas, 10.4 g ( 35.3 mmol ) of $\mathbf{1 5} / \mathbf{1 6}$ is added, and the yellowish suspension (!) is shaken under hydrogen gas (1 bar) until 940 ml (ca. $110 \%$ ) of $\mathrm{H}_{2}$ has been absorbed. The homogeneous and almost colorless solution is filtered (caution!), the catalyst is washed with some dioxane and the solvent evaporated to give an yellowish, oily residue. TLC control $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ shows complete conversion of the starting material. Redissolution of the residue in methanol and cooling to $-15^{\circ} \mathrm{C}$ afford a very loose gel which is quickly filtered by suction through a precooled Buchner funnel and dried in vacuo to give a lightbrown powder. Further material may be collected in the same way from the mother liquors to give crude 20 [total yield 7.4 g ( $71 \%$ ). In a series of runs, yields range from $60-83 \%$ ]. Further purification of this material by flash chromatography (silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) followed by recrystallization from $n$-hexane $/ \mathrm{CHCl}_{3}$ (ca. $12: 1$ ) gives colorless crystals; m.p. $77-80^{\circ} \mathrm{C}$. $-\mathrm{IR}(\mathrm{KBr}): \tilde{\mathrm{v}}=3059 \mathrm{~cm}^{-1}$, 3031, 2956, 2930, 2894, 2873, 1702, 1604, 1582, 786, 759, 705, 642, $614,605 .-{ }^{1} \mathrm{H}$ NMR $(300 \mathrm{MHz}): \delta=7.77\left(\mathrm{~d},{ }^{3} J=7.7 \mathrm{~Hz}, 1 \mathrm{H}\right)$,
$7.66\left(\mathrm{~d},{ }^{3} J=7.6 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.59\left(\mathrm{t},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.45\left(\mathrm{~d},{ }^{3} J=\right.$ $7.6 \mathrm{~Hz}, 1 \mathrm{H}), 7.05-7.32(\mathrm{~m}, 7 \mathrm{H}), 6.93\left(\mathrm{~d},{ }^{3} J=7.6 \mathrm{~Hz}, 1 \mathrm{H}\right)$, са. 6.74 (br m, 2 H ), $4.97\left(\mathrm{~d},{ }^{3} J=7.3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 4.94\left(\mathrm{~d},{ }^{3} J=\right.$ $\left.11.7 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 3.91\left(\mathrm{dd},{ }^{3} J=7.4,{ }^{3} J=11.7 \mathrm{~Hz}, 1 \mathrm{H}, 9 \mathrm{a}-\right.$ $\mathrm{H}) .-{ }^{13} \mathrm{C}$ NMR $(75 \mathrm{MHz}): \delta=205.1(\mathrm{~s}, \mathrm{C}=\mathrm{O}), 156.1(\mathrm{~s}), 145.6$ (s), 143.1 (s), 141.4 (s), 137.4 (s), 134.9 (d), 129.5 (d), 127.9 (d), 126.8 (d), 126.3 (d), 125.3 (d), 124.2 (d), 123.8 (d), 55.6 (d), 52.9 (d), 51.0 (d). - MS, $m / z(\%): 296(100)\left[\mathrm{M}^{\bullet+}\right], 295(21), 279$ (13), 278 (10), 267 (15), 265 (20), 252 (15), 239 (5), 219 (14), 218 (16), 194 (6), 191 (13), 189 (17), 165 (13). $-\mathrm{C}_{22} \mathrm{H}_{16} \mathrm{O}$ (296.4): calcd. (4ba,9aa)-4b,9,9a,10-Tetrahydro-10ß-phenylindeno/1,2-a]inden$9 \beta$-ol (27): To a stirred solution of $\mathrm{LiAlH}_{4}(190 \mathrm{mg}, 5.0 \mathrm{mmol})$ in dry diethyl ether is added a solution of $20(3.0 \mathrm{~g}, 10.0 \mathrm{mmol})$ in 100 ml of diethyl ether. The mixture is heated to reflux for 3 h ; TLC control $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}, R_{\mathrm{f}} \approx 0.6\right)$ shows that, apparently, only one product is formed. The mixture is cooled to $0^{\circ} \mathrm{C}$ and carefully hydrolyzed with ice water. After addition of aqueous $\mathrm{NH}_{4} \mathrm{Cl}$, the aqueous layer is extracted with diethyl ether, and the combined organic solutions are washed with water and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Evaporation of the solvent, eventually in vacuo $\left(100^{\circ} \mathrm{C}, 0.1 \mathrm{mbar}\right)$ furnishes a yellowish residue, which is further purified by column chromatography $\left(\mathrm{CHCl}_{3}\right)$ to give $27(3.0$, ca. $100 \%)$ as a colorless, glassy material. All attempts to crystallize the alcohol have been unsucessful; the crude material, however, may be used in the final cyclization step (see below). - IR (KBr): $\tilde{v}=3564 \mathrm{~cm}^{-1}(\mathrm{sh}, \mathrm{OH})$, 3457 (br, OH ) , 3067, 3028, 2932, 2885, 1597, 1493, 1473, 1452, 1400, 1110, 1089, 1046, 1020, 753, 700. - ${ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.56\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.45\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}, \mathrm{IH}\right), 7.27$ and $7.25\left(\right.$ two $\left.\mathrm{d},{ }^{3} J \approx 7.4 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.18\left(\mathrm{t},{ }^{3} J=7.3 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.0-7.15$ $(\mathrm{m}, 5 \mathrm{H}), 6.8 \mathrm{I}\left(\mathrm{dd},{ }^{3} J=7.7,{ }^{4} J \approx 1.5 \mathrm{~Hz}, 2 \mathrm{H}\right), 5.24\left[\mathrm{brt}\left(\mathrm{D}_{2} \mathrm{O}: \mathrm{d}\right)\right.$, $\left.{ }^{3} J=7.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHOH}\right), 4.80\left(\mathrm{~d},{ }^{3} J=9.2 \mathrm{~Hz}, 1 \mathrm{H}\right), 4.61\left(\mathrm{~d},{ }^{3} J=\right.$ $7.2 \mathrm{~Hz}, 1 \mathrm{H}), 3.85\left(\mathrm{dt},{ }^{3} J \approx 9.2,{ }^{3} J=7.2 \mathrm{~Hz}, 1 \mathrm{H}, 9 \mathrm{a}-\mathrm{H}\right), 1.3(\mathrm{br} \mathrm{s}$, $1 \mathrm{H}, \mathrm{OH}) .-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ): $\delta=146.4$ (s), 145.7 (s), 144.7 (s), 143.0 (s), 129.8 (d), 128.1 (d), 127.31 (d), 127.09 (d), 126.6 (d), 125.3 (d), 124.15 (d), 124.05 (d), 123.5 (d), 77.2 (d, CHOH), 53.9 (d), $53.3(\mathrm{~d}), 52.1(\mathrm{~d}) .-\mathrm{MS}, m / z(\%): 298(98)\left[\mathrm{M}^{\bullet+}\right], 297(20)$, 280 (100) [ $\left.\mathrm{M}^{\bullet+}-\mathrm{H}_{2} \mathrm{O}\right], 279(48), 278$ (11), 277 (9), 276 (6), 269 (6), 267 (9), 265 (29), 254 (12), 253 (17), 252 (18), 221 (43), 220 (32), 218 (11), 207 (20), 203 (57), 202 (30), 194 (11), 193 (11), 192 (25), 191 (22), 190 (12), 189 (25), 179 (13), 178 (28), 167 (21), 165 (34), 152 (9), 131 (9), 115 (16), 105 (23), 91 (29). - $\mathrm{C}_{22} \mathrm{H}_{18} \mathrm{O}$ (298.4): calcd. C 88.46, H 6.08 ; found C 88.06, H 6.36. - calcd. 298.1358 ; found 298.1354 (MS).

Attempted synthesis of (4ba,9aa)-4b,9,9a,10-Tetrahydro-10ß-phe-nylindeno[1,2-a ]inden-9a-ol (26): To a solution of $\mathrm{Al}(\mathrm{OiPr})_{3}(0.8 \mathrm{~g})$ in 15 ml of 2-propanol is slowly added a solution of $20(0.70 \mathrm{~g}, 2.4$ mmol ) in 25 ml of dry toluene. The mixture is heated under the same conditions used for the reduction of the $10 \alpha$-phenyl isomer $(\mathbf{8} \rightarrow \mathbf{1 0}$, see above). No reaction is observed after a total of 30 h , whereas $8(100 \mathrm{mg})$, added for control purposes, does react to furnish 10 (TLC control). Heating to reflux after exchange of the toluene for xylene and addition of further 0.4 g of the reagent is also non-productive; workup and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis reveal essentially unchanged starting ketone 20.
(4ba,8ba,12ba,12da)-4b,8b,12b,12d-Tetrahydrodibenzo[2,3:4,5]-pentaleno[1,6-ab]indene, Tribenzotriquinacene (4): A mixture of orthophosphoric acid $(85 \%, 0.4 \mathrm{ml})$ and 100 ml of toluene is heated in a water separator for 2 h . After cooling to ca. $60^{\circ} \mathrm{C}, 27(3.0 \mathrm{~g}$, 10 mmol ) is added, and heating is continued for 18 h with vigorous stirring. The product may precipitate partially from the hot reaction mixture and, upon cooling to room temp., readily crystallizes
quantitatively as fine, colorless needles. The crystals are collected by suction and washed with some cold ethanol to give $4(1.6 \mathrm{~g}$, $57 \%$ ) which may be recrystallized from 200 ml (!) of hot xylene to furnish the hydrocarbon as thin and long, colorless needles; m.p. $390-391^{\circ} \mathrm{C}$. All spectroscopic data are identical with those published previously (see refs. ${ }^{[4.31]}$ and discussion). - Alternatively, the dehydration may be carried out by heating of a solution of 27 (1.90 $\mathrm{g}, 6.4 \mathrm{mmol}$ ) in 100 ml of benzene with 0.6 g of Amberlyst A-15 for 3 h . The product starts precipitating after $5-10 \mathrm{~min}$; workup and recrystallization from xylene give 4 ( $1.05 \mathrm{~g}, 59 \%$ ).
(4ba,9aa)-4b,9,9a,10-Tetrahydro-9a-phenylindeno[1,2-a]indene (28): A solution of $2.96 \mathrm{~g}(10.0 \mathrm{mmol})$ of 8 in 100 ml of ethanol is shaken with 0.3 g of $\mathrm{Pd} / \mathrm{C}\left(10 \%\right.$, Merck) at $50^{\circ} \mathrm{C}$ under hydrogen ( 5 bar ) for 12 h . Workup of the cooled reaction mixture and recrystallization of the crude product from ethanol gives $28(2.26 \mathrm{~g}, 80 \%)$ as colorless crystals; m.p. $109-110^{\circ} \mathrm{C}$. This hydrocarbon has been obtained previously by Wolff-Kishner reduction of 8, m.p. $112^{\circ} \mathrm{C}^{[2]}$.

- IR (KBr): $\tilde{v}=3063 \mathrm{~cm}^{-1}, 3027,2975,2939,2905,2860,2844$, $1596,1583,1491,1470,1452,1440,802,761,741,713,689,627$, 610. - ${ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.53\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right)$, $7.10-7.38(\mathrm{~m}, 11 \mathrm{H}), 6.85\left(\mathrm{~d},{ }^{3} J=7.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 4.78\left(\mathrm{~d},{ }^{3} J=7.6\right.$ $\left.\mathrm{Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 4.02\left(\mathrm{~d},{ }^{3} J=7.1 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 3.38\left(\mathrm{qt},{ }^{3} J \approx\right.$ $\left.7.5,{ }^{3} J_{(\mathrm{AM})}=2.5 \mathrm{~Hz}, 1 \mathrm{H}, 9 \mathrm{a}-\mathrm{H}\right), \mathrm{ABM}$ spin system $\delta_{\mathrm{M}}=3.38$, $\delta_{\mathrm{B}}=3.21, \delta_{\mathrm{A}}=3.01\left({ }^{2} J_{\mathrm{AB}}=-16.2,{ }^{3} J_{\mathrm{AM}}=2.4,{ }^{3} J_{\mathrm{BM}}=7.7 \mathrm{~Hz}\right.$, $3 \mathrm{H}, \mathrm{CH}_{2}, \mathrm{CHAr}_{2}$ ) $-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ) $\delta=146.3$ (s), 144.92 (s), 144.87 ( s$), 143.5$ ( s$), 142.4$ (s), 128.6 (d), 128.4 (d), 127.16 (d), 127.10 (d), 126.84 (d), 126.76 (d), 126.5 (d), 125.1 (d), 124.5 (d), $124.0(\mathrm{~d}), 57.7(\mathrm{~d}), 55.6(\mathrm{~d}), 54.8(\mathrm{~d}), 37.1(\mathrm{t}),-\mathrm{MS}, m / z(\%): 282$ (67) $\left[\mathrm{M}^{\bullet+}\right], 281$ (9), 280 (6), 278 (3), 277 (4), 276 (4), 267 (5), 266 (5), 265 (11), 252 (7), 239 (4), 205 (7), 204 (13), 203 (25), 202 (19), 191 (100), 167 (13), 165 (10). $-\mathrm{C}_{22} \mathrm{H}_{18}$ (282.4): calcd. (4ba,9aa)-4b,9,9a,10-Tetrahydro-9ß-phenylindeno[1,2-a]indene (29): A solution of $0.20 \mathrm{~g}(670 \mu \mathrm{~mol})$ of 20 in 40 ml of ethanol is shaken with 0.1 g of $\mathrm{Pd} / \mathrm{C}\left(10 \%\right.$, Merck) at $55^{\circ} \mathrm{C}$ under hydrogen ( 5 bar) overnight. Workup of the cooled reaction mixture followed by kugelrohr distillation ( $220^{\circ} \mathrm{C} / 0.1 \mathrm{mbar}$ ) of the crude product and recrystallization from ethanol give $29(0.14 \mathrm{~g}, 74 \%)$ as colorless crystals; m.p. $81-82^{\circ} \mathrm{C}$. $-\mathrm{IR}(\mathrm{KBr}): \tilde{v}=3065 \mathrm{~cm}^{-1}, 3019,2960$, $2931,2895,2861,2839,1603,1577,1491,1475,1450,1431,1392$, $799,761,750,729,719,703,687,672,610 .-{ }^{1} \mathrm{H}$ NMR ( 300 MHz ): $\delta=7.51\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.41\left(\mathrm{~d},{ }^{3} J=6.9 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.13-7.33$ $(\mathrm{m}, 9 \mathrm{H}), 7.09\left(\mathrm{t},{ }^{3} J=7.3 \mathrm{~Hz}, 1 \mathrm{H}\right), 6.96\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}, 1 \mathrm{H}\right), 4.78$ $\left(\mathrm{d},{ }^{3} J=8.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right), 4.69\left(\mathrm{~d},{ }^{3} J=7.6 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CHAr}_{2}\right)$, 3.69 (quint, ${ }^{3} J \approx 8.1 \mathrm{~Hz}, 1 \mathrm{H}, 9 \mathrm{a}-\mathrm{H}$ ), ABX spin system $\delta_{\mathrm{X}}=3.69$, $\delta_{\mathrm{B}}=2.59, \delta_{\mathrm{A}}=2.52\left({ }^{2} J_{\mathrm{AB}}=-16.6,{ }^{3} J_{\mathrm{AX}}=9.0,{ }^{3} J_{\mathrm{BX}}=7.9 \mathrm{~Hz}\right.$, $3 \mathrm{H}, \mathrm{CH}_{2}, \mathrm{CHAr}_{2}$ ).$-{ }^{13} \mathrm{C}$ NMR ( 75 MHz ) $\delta=144.9(\mathrm{~s}), 144.6$ ( s$), 144.1$ (s), 143.5 (s), 141.6 (s), 129.2 (d), 128.1 (d), 127.1 (d), 126.85 (d), 126.77 (d), 126.4 (d), 125.9 (d), 124.6 (d), 124.4 (d), 123.8 (d), 55.5 (d), 53.2 (d), 49.7 (d), 34.0 (t). $-\mathrm{MS}, m / z(\%): 282$ (100) $\left[\mathrm{M}^{\bullet+}\right], 281(21), 280(8), 279(6), 267(9), 266(6), 265(12)$, 252 (6), 205 (16), 204 (36), 203 (33), 202 (11), 191 (71), 178 (8), 167 (44), 165 (7). $-\mathrm{C}_{22} \mathrm{H}_{18}$ (282.4): calcd. C 93.58, H 6.42 ; found C 93.47 , H 6.65.

## 9,10-Dihydro-10-phenylindeno[1,2-a ]indene (30)

a) By dehydration of 9 and 27 with DMSO: A solution of 0.50 g ( 1.68 mmol ) of 9 (or the stereoisomer 27 ) in 5.0 ml of freshly distilled dimethyl sulfoxide is heated under nitrogen at $175^{\circ} \mathrm{C}$ for 6 h . The mixture is allowed to cool under nitrogen, diluted with 10 ml of water and extracted with $n$-hexane. The extract is washed with water and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Evaporation of the solvent gives an oily residue which is subjected to MPLC (Kieselgel 60/chloroform)
to give $95-115 \mathrm{mg}\left(20-25^{\circ} / 1\right)$ of a colorless oil. Both in the case of 9 and 27 , the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra of the products are identical with those of the crystalline product described below.
b) By Cyclodehydration of 2-Benzhydryl-1,3-indandiol: As described recently ${ }^{[2]}$, a mixture of $10.5 \mathrm{~g}(33.0 \mathrm{mmol})$ of $34,80 \mathrm{ml}$ of chlorobenzene, and 5.0 ml of orthophosphoric acid ( $85 \%$ ) is allowed to react at $120^{\circ} \mathrm{C}$ (bath temp.) for 20 h . The readily crystallizing 4 is quantitatively separated by filtration (yield $11 \%{ }^{[2]}$ ), and the filtrate is concentrated to give a yellow oil. Kugelrohr distillation ( $170-190^{\circ} \mathrm{C}, 0.1 \mathrm{mbar}$ ) followed by recrystallization from ethanol gives $30(2.80 \mathrm{~g}, 30 \%)$; m.p. $185^{\circ} \mathrm{C}$. - IR (KBr): $\tilde{\mathrm{v}}=3061 \mathrm{~cm}^{-1}$, 3028, 2902, 2886, 2768, 1599, 1491, 1479, 1451, 1395, 772, 757, $739,728,713,701,643,609 .-{ }^{1} \mathrm{H}$ NMR ( 300 MHz ) $\delta=7.78(\mathrm{~d}$, $\left.{ }^{3} J=7.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.75\left(\mathrm{~d},{ }^{3} J=7.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.48\left(\mathrm{~d},{ }^{3} J=7.4 \mathrm{~Hz}\right.$, $1 \mathrm{H}), 6.10-7.40(\mathrm{~m}, 8 \mathrm{H}), 7.10\left(\mathrm{dd},{ }^{3} J=7.8,{ }^{4} J \approx 1.6 \mathrm{~Hz}, 2 \mathrm{H}\right)$, $4.79(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CHAr}), \mathrm{AB}$ spin system $\delta_{\mathrm{A}}=3.51, \delta_{\mathrm{B}}=3.42\left({ }^{2} \mathrm{~J}=\right.$ $\left.-23.4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2}\right) .-{ }^{13} \mathrm{C}$ NMR $(75 \mathrm{MHz}): \delta=157.9(\mathrm{~s}), 152.8$ (s), 148.0 (s), 147.5 (s), 140.0 (s), 139.3 (s), 138.7 (s), 128.8 (d), 127.9 (d), 126.89 (d), 126.84 (d), 126.54 (d), 125.06 (d), 124.77 (d), 124.69 (d), 119.91 (d), 119.65 (d), 53.1 (d, C-4b), 34.5 (t, C-9). MS, $m / \tau(\%): 280(100)\left[\mathrm{M}^{\bullet+}\right], 279(44), 278(12), 277(10), 276$ (14), 265 (5), 263 (3), 252 (6), 203 (53), 202 (47), 201 (5), 200 (7), $178(6), 139(8), 138(12) .-\mathrm{C}_{22} \mathrm{H}_{16}(280.4)$ : calcd. C 94.25, H 5.75; found C 94.13, H 5.95.

The ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of $\mathbf{3 0}$ allows us to distinguish between this olefin and the isomer 32 in the following way: The two low-field arene doublets at $\delta=7.78$ and 7.75 are assigned to $4-\mathrm{H}$ and $5-\mathrm{H}$, in parallel to the features of many other diindan derivatives presented in this work. Correspondingly, the high-field arene double doublet at $\delta=7.10$ is attributed to the ortho-protons of the phenyl group. The benzhydrylic methine singlet $(\delta=4.79$ ) clearly shows crosspeaks with only one of the low-field arene signals (viz. that at $\delta=7.78$ ), and, in addition, with the low-field signal at $\delta=$ 7.10. In turn, the methylene AB system $(\delta=3.51$ and 3.42$)$ exhibits only one characteristic crosspeak with just the other low-field doublet $(\delta=7.75)$. This clearly rules out the presence of a "quasisymmetrical" methine proton at C-4b anticipated for $\mathbf{3 2}$ but is in full accordance with the structure of $\mathbf{3 0}$.
