<b>IV. List of figures in the Supplement .....</b>	<b>xi</b>
<b>V. List of videos in the Supplement/DVD .....</b>	<b>xii</b>
<b>VI. List of Abbreviations .....</b>	<b>xiii</b>
Summary .....	1
Zusammenfassung .....	2
<b>1. Introduction .....</b>	<b>4</b>
<b>1.1 Components of mammalian STRIPAK complex .....</b>	<b>6</b>
1.1.1 Striatins .....	6
1.1.2 PP2A.....	8
1.1.3 STRIP1/2.....	9
1.1.4 SLMAP/TRAF3IPS .....	10
1.1.5 CTTNBP2/CTTNBP2NL.....	11
1.1.6 MOB3 (phocein).....	12
1.1.7 Germinal center kinases and CCM3.....	13
1.1.7.1 MST3.....	14
1.1.7.2 MST4 and STK25 .....	14
1.1.7.3 MINK .....	14
1.1.8 SIKE/FGFR1OP2.....	15

## Table of Contents

1.1.8.1	SIKE.....	15
1.1.8.2	FGFR1OP2 .....	15
<b>1.2</b>	<b>STRIPAK-like complexes in yeasts and in <i>Drosophila melanogaster</i> .....</b>	<b>16</b>
1.2.1	The SIP-SIN-MOR crosstalk in <i>S. pombe</i> .....	16
1.2.2	The Far complex in <i>Saccharomyces cerevisiae</i> .....	18
1.2.2.1	The Far complex in <i>S. cerevisiae</i> is involved in pheromone-mediated cell cycle arrest.....	18
1.2.2.2	The Far complex regulates cell growth, autophagy and actin polarization .....	20
1.2.2.3	MEN regulates mitotic exit and cytokinesis in <i>S. cerevisiae</i> .....	21
1.2.3	STRIPAK complex in <i>Drosophila melanogaster</i> .....	22
1.2.3.1	Hippo signaling in <i>D. melanogaster</i> .....	22
1.2.3.2	Cka in the Jun-N-terminal kinase pathway in <i>D. melanogaster</i> .....	24
1.2.3.3	The dSTRIPAK activates the Ras-Raf-MAPK/ERK pathway .....	25
<b>1.3</b>	<b><i>Sordaria macrospora</i> is a model organism to study fruiting-body development .....</b>	<b>26</b>
1.3.1	The STRIPAK complex in <i>S. macrospora</i> regulates sexual development and hyphal fusion.....	27
1.3.2	Striatin orthologs in filamentous fungi control hyphal fusion, sexual development and vegetative growth.....	28
1.3.3	Fungal MOB3 proteins are involved in hyphal fusion, development and vesicular traffic.....	29
1.3.4	The fungal STRIP1/2 ortholog and the catalytic PP2ac1 subunit link the fungal STRIPAK to septation and the CWI pathway.....	30
1.3.5	The SLMAP ortholog PRO45 is part of the fungal STRIPAK complex in <i>S. macrospora</i> .....	31
1.3.6	Fungal STRIPAK-associated proteins SmGPI1 and GCKIII kinases SmKIN3 and SmKIN24 .....	31
<b>1.4</b>	<b>Aims of this thesis.....</b>	<b>32</b>
<b>2.</b>	<b>Materials and Methods .....</b>	<b>34</b>

## Table of Contents

<b>2.1 Materials</b> .....	<b>34</b>
2.1.1 Strains .....	34
2.1.2 Plasmids .....	38
2.1.3 Primers.....	41
2.1.4 Chemicals and materials.....	46
2.1.4.1 Chemicals.....	46
2.1.4.2 Materials.....	47
2.1.5 Kits .....	47
2.1.6 Enzymes .....	48
2.1.7 Antibodies.....	48
2.1.8 Buffers and solutions .....	48
2.1.9 Media.....	51
<b>2.2 Methods</b> .....	<b>52</b>
2.2.1 Cultivation of microorganisms.....	52
2.2.2 Preparation of competent microorganisms and transformation procedure .....	53
2.2.3 Generation of <i>S. macrospora</i> deletion strains.....	54
2.2.3.1 Generation of <i>S. macrospora</i> single deletion strains .....	54
2.2.3.2 Generation of <i>S. macrospora</i> double deletion strains .....	55
2.2.4 Generation of <i>sci1</i> expression plasmids for transformation into <i>S. macrospora</i> .	56
2.2.4.1 Generation of <i>sci1</i> full length constructs for transformation into <i>S. macrospora</i> .....	56
2.2.4.2 Construction of plasmids containing fragments of <i>sci1</i> and transformation into <i>S. macrospora</i> .....	56
2.2.5 Transformation of wt <i>S. macrospora</i> strains with pHA_nat and pFLAG_nat .....	57
2.2.6 Generation of expression plasmids for complementation attempts of <i>S. macrospora</i> with the mammalian FGFR1OP2 and yeast Far3 and Far7 .....	58
2.2.7 Generation of <i>S. macrospora</i> strains expressing fluorescent fusion proteins .....	58

## Table of Contents

2.2.7.1	Complementation of the $\Delta$ sci1 <sub>hyg</sub> $\Delta$ pro11 strain.....	58
2.2.7.2	Generation of <i>S. macrospora</i> strains for analysis of nuclei, mitochondria, ER, actin, nuclear envelope as well as early and late endosomes with fluorescence microscopy .....	59
2.2.7.3	Generation of SmPOM152 expression plasmid for transformation into <i>S. macrospora</i> .....	59
2.2.7.4	Generation of $\Delta$ pro11::hapro11egfp strain.....	59
2.2.8	Molecular biology methods: nucleic acids.....	59
2.2.8.1	PCR .....	59
2.2.8.2	Separation of nucleic acids with agarose-gel electrophoresis .....	60
2.2.8.3	Purification of nucleic acids .....	60
2.2.8.4	Hydrolysis and ligation of nucleic acids .....	61
2.2.8.5	Isolation of plasmid DNA from <i>E. coli</i> .....	61
2.2.8.6	Isolation of plasmid DNA from <i>S. cerevisiae</i> .....	61
2.2.8.7	Isolation of RNA and genomic DNA from <i>S. macrospora</i> .....	61
2.2.8.8	Southern blotting and hybridization.....	62
2.2.8.9	Synthesis of cDNA and qRT-PCR .....	62
2.2.8.10	Synthesis of oligonucleotides and sequencing.....	63
2.2.9	Molecular biology methods: proteins.....	63
2.2.9.1	Isolation of proteins from <i>S. macrospora</i> .....	63
2.2.9.2	Determination of protein concentration .....	63
2.2.9.3	SDS-PAGE .....	64
2.2.9.4	Western blotting.....	64
2.2.9.5	Coomassie staining of polyacrylamide gels .....	64
2.2.9.6	Trypsin digest, stage tipping and sample preparation .....	65
2.2.9.7	Liquid chromatography-mass spectrometry analyses.....	67
2.2.10	Y2H and drop test.....	67
2.2.11	Analytical methods.....	69

## Table of Contents

2.2.11.1 Light and fluorescence microscopy .....	69
2.2.11.2 DNA and protein sequence analysis.....	70
2.2.11.3 Phylogenetic analysis.....	70
2.2.11.4 LC-MS data analysis: MaxQuant/Perseus and Proteome Discoverer™..	70
2.2.12 Measures of safety .....	72
<b>3. Results.....</b>	<b>73</b>
<b>3.1 Pull-down experiments and LC/MS with the STRIPAK proteins PRO11 and SmMOB3 .</b>	<b>73</b>
3.1.1 LC/MS data analysis with MaxQuant/Perseus identified a putative interaction partner of PRO11 with high confidence .....	73
3.1.2 LC/MS Data analysis with the Proteome Discoverer™ identified several putative interaction partners of PRO11 and SmMOB3 .....	76
<b>3.2 Small coiled-coil proteins that associate with the STRIPAK complex in fungi and animals are conserved through their domain structure .....</b>	<b>77</b>
<b>3.3 Small CC proteins associated with the STRIPAK complex are conserved within phyla belonging to distant clades .....</b>	<b>78</b>
<b>3.4 SCI1 proteins are conserved in filamentous ascomycetes .....</b>	<b>80</b>
<b>3.5 The <i>sci1</i> gene is upregulated during sexual development.....</b>	<b>81</b>
<b>3.6 Successful generation of a <i>sci1</i> deletion strain.....</b>	<b>82</b>
<b>3.7 Macroscopic and microscopic analysis of the <math>\Delta sci1_{hyg}</math> strain.....</b>	<b>84</b>
3.7.1 The <i>sci1</i> deletion strain is sterile, produces less protoperithecia than the wt and is devoid of hyphal fusion.....	84
3.7.2 The vegetative growth rate of the $\Delta sci1_{hyg}$ and the $\Delta sci1_{hyg}\Delta pro11$ strain is reduced.....	86
3.7.3 Growth of the $\Delta sci1_{hyg}$ strain is slightly increased in presence of H <sub>2</sub> O <sub>2</sub> and CaCl <sub>2</sub> or under nitrogen-limiting conditions .....	88
<b>3.8 SCI1 oligomerizes and interacts with PRO11 and PRO45 in yeast two-hybrid experiments .....</b>	<b>89</b>
3.8.1 The central region of SCI1 complements the sterile phenotype of $\Delta sci1_{hyg}$ .....	91
<b>3.9 PRO11 was enriched in SCI1eGFP pull-downs .....</b>	<b>92</b>
<b>3.10 Functional conservation of SCI1.....</b>	<b>94</b>

## Table of Contents

3.10.1 Mammalian FGFR1OP2 and yeast Far3/7 do not complement the sterile phenotype of $\Delta sci1_{hyg}$ .....	94
3.10.2 SCI1 interacts with Far3 and Far7 but not with Far8 in Y2H experiments.....	94
<b>3.11 SCI1 and PRO11 colocalize at the nuclear envelope .....</b>	<b>96</b>
<b>3.12 Analysis of cellular components in <math>\Delta sci1</math> .....</b>	<b>98</b>
3.12.1 <i>sci1</i> deletion does not interfere with nuclear transport.....	98
3.12.2 Mitochondria appeared similar in the wt and in <i>sci1</i> deletion strains.....	99
3.12.3 Endoplasmic reticulum in the $\Delta sci1_{hyg}$ background appears normal.....	99
3.12.4 Actin polymerization and septum formation is not impaired in the <i>sci1</i> background.....	100
3.12.5 Visualization of early and late endosomal marker proteins in the wt and the <i>sci1</i> deletion background .....	101
3.12.5.1 The early endosome marker eGFPZtRab5 accumulates in hyphae of the $\Delta sci1_{nat}$ background .....	102
3.12.5.2 The late endosome marker eGFPZtRab7 in the $\Delta sci1_{nat}$ background visualizes abnormal vacuolar morphology and behavior .....	104
<b>4. Discussion .....</b>	<b>107</b>
<b>4.1 SCI1, a new PRO11 interaction partner was identified in <i>S. macrospora</i> .....</b>	<b>108</b>
<b>4.2 SCI1 is a small protein containing coiled-coil domains .....</b>	<b>109</b>
<b>4.3 Deletion of <i>sci1</i> causes sterility and prevents hyphal fusion in <i>S. macrospora</i> .....</b>	<b>110</b>
<b>4.4 <i>sci1</i> is up-regulated during sexual development .....</b>	<b>112</b>
<b>4.5 The central region of SCI1 oligomerizes and interacts with PRO11 .....</b>	<b>114</b>
<b>4.6 Functional conservation of STRIPAK complex-associated proteins containing coiled-coil domains .....</b>	<b>115</b>
<b>4.7 SCI1 is part of the core SmSTRIPAK complex in <i>S. macrospora</i> .....</b>	<b>116</b>
<b>4.8 SCI1 and PRO11 colocalize at the nuclear envelope .....</b>	<b>117</b>
<b>4.9 SCI1 might be involved in vesicular transport .....</b>	<b>119</b>
4.9.1 The STRIPAK complex has a role in ER to Golgi transport .....	120
4.9.2 The STRIPAK complex is connected to microtubules and Golgi inheritance .....	122

## List of Abbreviations

### VI. List of Abbreviations

AA	amino acids
AD	activation domain
BLAST	basic local alignment search tool
BMM	biomalt maize medium
BD	binding domain
bp	base pair
CC	coiled-coil
CCM3	cerebral cavernous malformation 3
cDNA	complementary DNA
CMS	complex rich medium with 10.8% sucrose
Ct	threshold cycle
CTTNBP2	cortactin-binding protein 2
CWI	cell wall integrity
DIC	differential interference contrast
DsRED	encodes red fluorescence protein of <i>Discosoma</i> sp
eGFP	enhanced green fluorescent protein
ER	endoplasmic reticulum
FAR	factor arrest
FGFR1	fibroblast growth factor receptor 1
FGFR1OP2	fibroblast growth factor receptor oncogene partner 2
gDNA	genomic DNA
HAM	hyphal anastomosis
IFN	interferon
kDa	kilo Dalton
LC/MS	liquid chromatography/ mass spectrometry
MAP	mitogen-activated protein
MAPK	mitogen-activated protein kinase
MMS	minimal medium containing soluble starch
NDPK	nucleoside diphosphate kinase
NE	nuclear envelope
NF- $\kappa$ B	nuclear factor kappa-light-chain-enhancer of activated B-cells
ORF	open-reading frame
PAGE	polyacrylamide gel electrophoresis
PCR	polymerase chain reaction
PRO11	protoperithecium mutant 11
PRO22	protoperithecium mutant 22
PRO45	protoperithecium mutant 45
pT	primary transformant

## List of Abbreviations

qRT-PCR	quantitative reverse-transcription PCR
REST	relative gene expression approach
RNA	ribonucleic acid
SCI1	STRIPAK complex interactor 1
SDS	sodium dodecyl sulfate
SIKE	suppressor of IKK $\epsilon$
SLMAP	sarcolemmal membrane-associated protein
ssDNA	salmon sperm DNA
ssi	single spore isolate
SMART	simple modular architecture research tool
<i>SmGPI</i>	<i>Sordaria macrospora</i> glycosylphosphatidylinositol
<i>SmKIN3</i>	<i>Sordaria macrospora</i> germinal center kinase 3
<i>SmKIN24</i>	<i>Sordaria macrospora</i> germinal center kinase 24
<i>SmMOB3</i>	<i>Sordaria macrospora</i> monopolar spindle one binder 3
<i>SmPP2AA</i>	<i>Sordaria macrospora</i> protein phosphatase 2A
<i>SmPP2Ac1</i>	<i>Sordaria macrospora</i> catalytic subunit 1 of protein phosphatase 2A
STRIP	Striatin-interacting protein
STRIPAK	Striatin-interacting phosphatase and kinase complex
SWG	<i>Sordaria</i> Westergaards medium
TAP-MS	tandem affinity purification-mass spectrometry
TBK1	TANK-binding kinase 1
TLR3	toll-like receptor 3
TRIF	TIR domain-containing adaptor protein
YPD	yeast extract, peptone, dextrose
wt	wild type

## Summary

The striatin-interacting phosphatase and kinase (STRIPAK) complex is conserved in fungi and animals. The STRIPAK in the filamentous ascomycete *Sordaria macrospora*, was previously found to be essential for hyphal fusion and fruiting-body development. STRIPAK orthologs in *S. macrospora* are PRO11 (striatin), PRO22 (STRIP1/2), PRO45 (SLMAP), the serine-threonine phosphatase scaffolding subunit PP2AA and the catalytic subunit SmPP2Ac1 as well as the kinase activator SmMOB3. In this study, PRO11 and SmMOB3 pull-down coupled to liquid chromatography and mass spectrometry (LC/MS) was performed and the LC/MS data was analyzed for putative interaction partners. Among, others an uncharacterized protein was identified as putative PRO11 interaction partner with very high confidence. The uncharacterized protein was named STRIPAK complex interactor 1 (SCI1). SCI1 is an ortholog of small coiled-coil (CC) domain(s) containing proteins found in STRIPAK complexes of yeasts, the fruit fly and mammals. Small CC proteins were discovered in the STRIPAK of *Homo sapiens*, *Drosophila melanogaster*, *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe*, but their function in the individual STRIPAK complexes is hardly investigated.

This study gives insights into the function of the small CC protein SCI1. The STRIPAK complex was also described in other filamentous fungi and this work shows that SCI proteins are conserved in filamentous ascomycetes. The *sci1* gene is expressed during early developmental stages. Like other STRIPAK genes, *sci1* is required for cell to cell fusion and sexual development in *S. macrospora*. Using yeast two-hybrid experiments oligomerization of SCI1, and direct interaction of SCI1 with PRO11 and PRO45 was shown. In fluorescence microscopy, fluorophore-tagged SCI1 and PRO11 fusion proteins showed that SCI1 colocalizes with PRO11 to the nuclear envelope. Additionally, proteins enriched in SCI1eGFP pull-downs were identified with LC/MS and PRO11 was highly enriched. Morphology of nuclei, the ER and mitochondria appeared normal in the *S. macrospora sci1* deletion mutant in comparison to the wild type (wt). Also, actin polymerization in vegetative hyphae was similar. However, studies with eGFP-tagged reporter proteins of early and late endosomes of *Zyoseptoria tritici*, Rab5 and Rab7 respectively, in the *S. macrospora sci1* deletion background strongly indicate a defect in vesicle and vacuolar transport. In this study SCI1 was also connected to the Golgi and might be important for vesicle or vacuole transport along microtubules. This is the first study, showing that SCI1 represents a component of the STRIPAK complex in *S. macrospora*. The results indicate that SCI1 and the

STRIPAK complex are involved in fundamental processes in eukaryotic cells such as transport of vesicles and long distance transport. These processes are important for sexual development, cell fusion and give insights into normal cell function in fungi and animals.

### Zusammenfassung

Der STRIPAK (striatin-interacting phosphatase and kinase)-Komplex ist in Pilzen und Tieren konserviert. In dem filamentösen Askomyceten *Sordaria macrospora* ist der STRIPAK Komplex an der Hyphenfusion und Entwicklung von Fruchtkörpern beteiligt. Orthologe STRIPAK Proteine in *S. macrospora* umfassen PRO11 (striatin), PRO22 (STRIP1/2), die Gerüstuntereinheit der Serin-Threonin-Phosphatase SmPP2AA, die katalytische Phosphatase Untereinheit SmPP2Ac1 und den Kinase Aktivator SmMOB3. PRO11 und SmMOB3 sowie putative Interaktionspartner wurden affinitäts-chromatographisch angereichert, und massenspektrometrisch untersucht. Von mehreren spezifisch angereicherten Proteinen konnte ein Protein mit sehr hoher Wahrscheinlichkeit als möglicher Interaktionspartner von PRO11 identifiziert werden. Dieses Protein wurde „STRIPAK complex interactor 1“ (SCI1) genannt. Für SCI1 wurden kleine „coiled-coil“ (CC) Domänen vorhergesagt. Auch in anderen Organismen assoziieren kleine „CC“ Proteine mit STRIPAK Komponenten. Obwohl diese kleinen „CC“ Proteine in STRIPAK Komplexen von *Homo sapiens*, *Drosophila melanogaster*, *Saccharomyces cerevisiae* und *Schizosaccharomyces pombe* entdeckt wurden, ist ihre Funktion weitgehend unerforscht.

In dieser Studie wurde das kleine „CC“ Proteine SCI1 funktionell untersucht. SCI Proteine sind in filamentösen Askomyceten konserviert. In *S. macrospora* ist das Transkriptionslevel des *sci1* Gens in der frühen sexuellen Entwicklung erhöht. Wie auch die anderen STRIPAK Gene, ist *sci1* wichtig für die Hyphenfusion und die Entwicklung von Fruchtkörpern. Hefe-Zwei-Hybrid-Analysen zeigten, dass SCI1 oligomerisiert und auch mit PRO11 und PRO45 interagiert. In mikroskopischen Untersuchungen mit SCI1 oder PRO11 Fluoreszenzmarker-Fusionsproteinen, lokalisierten und kolokalisierten SCI1 und PRO11 an der Kernhülle. SCI1 wurde affinitäts-chromatographisch angereichert und die Proben mittels Massenspektrometrie auf potentielle Interaktionspartner untersucht. PRO11 wurde sehr stark angereichert. In mikroskopischen Untersuchungen von Fluoreszenzmarker-Fusionsproteinen, die Kerne, das Endoplasmatische Retikulum, Mitochondrien oder Aktin Polymerisation visualisierten, konnten keine Unterschiede zwischen

## Summary/Zusammenfassung

dem Wildtyp und der *sci1 S. macrospora* Deletionsmutante festgestellt werden. Fluoreszenzmarker-Fusionsproteine eGFPZtRab5 und eGFPZtRab7 aus *Zymoseptoria tritici*, für frühe und späte Endosomen wurden in den Wildtyp und in die *sci1 S. macrospora* Deletionsmutante eingebracht um den Vesikeltransport zu untersuchen. Die Ergebnisse weisen drauf hin, dass der Vesikeltransport, welcher auch den Golgi Apparat einschließt in der *sci1* Deletionsmutante gestört sind. Weiterhin wird eine Beteiligung von Mikrotubuli vermutet, entweder bei der Ladung von Fracht-Vesikeln auf Mikrotubuli oder direkt beim Transport.

Diese Studie zeigt zum ersten Mal, dass SCI1 ein Teil des STRIPAK Komplexes in *S. macrospora* ist. Weiterhin lassen die Ergebnisse dieser Studie darauf schließen, dass SCI1 und somit auch der STRIPAK Komplex in fundamentale Prozesse in eukaryotischen Zellen wie Kommunikation über längere Distanzen und Transport von Vesikeln beteiligt sind. Diese Prozesse stehen im engen Zusammenhang mit sexueller Entwicklung und Zellfusion und sind maßgeblich für das Verständnis normaler Zellfunktion in Pilzen und Tieren.

## 1. Introduction

Cell development and differentiation in eukaryotes requires tightly regulated signaling pathways, involving corresponding scaffold proteins. Striatins are scaffold proteins in mammals detected in the central and peripheral nervous systems (Benoist *et al.*, 2006, Castets *et al.*, 1996, Castets *et al.*, 2000). They have specialized functions but the presence of striatins in other tissues, for example in fibroblasts, liver cells, skeletal-muscle and cardiac-muscle cells indicates at least one common function (Moreno *et al.*, 2000, Muro *et al.*, 1995, Castets *et al.*, 2000). Striatins are part of the striatin-interacting phosphatase and kinase complex (STRIPAK) presented in figure 1. In mammals, STRIPAK components are the protein phosphatase 2 A catalytic subunit (PP2Ac), the scaffolding protein phosphatase 2 A alpha isoform (PP2AA), the regulatory B''' subunits (striatins), the monopolar spindle one binder 3 (MOB3), cerebral cavernous malformation 3 (CCM3), striatin-interacting proteins 1 and 2 (STRIP1/2) and members of the germinal center kinase III (GCKIII) family of Ste20 kinases. Mutually exclusive interactions allow binding of either the sarcolemmal membrane-associated protein (SLMAP) in the sub-complex I or the cortactin-binding protein 2 (CTTNBP2/ CTTNBP2NL) in the sub-complex II (Goudreault *et al.*, 2009).

**Figure 1: STRIPAK complex in mammals**

Schematic representation of both mammalian STRIPAK sub-complexes. PP2AA: scaffolding subunit of phosphatase 2 A, PP2Ac: catalytic subunit of phosphatase 2 A, MOB3 (phoecin): monopolar spindle one binder 3, CCM3: cerebral cavernous malformation 3, STRIP1/2: striatin-interacting proteins 1 and 2, GCKIII: germinal center kinase III, CTTNBP2/ CTTNBP2NL: cortactin-binding protein 2, SLMAP: sarcolemmal membrane-associated protein, SIKE: suppressor of IKK $\epsilon$ , FGFR1OP2: fibroblast growth factor receptor 1 oncogene partner 2. Modified according to Goudreault *et al.*, 2009.

Furthermore, alternative human STRIPAK components are two related small coiled-coil (CC) proteins, either suppressor of IKK $\epsilon$  (SIKE) or the fibroblast growth factor receptor 1 oncogene

partner 2 (FGFR1OP2) that associate with the protein SLMAP (Goudreault *et al.*, 2009). However, the function of small CC proteins in the STRIPAK complex is largely unclear.

**Table 1: STRIPAK complex in human, yeasts, fruit fly and filamentous fungi**

Dark blue: Core STRIPAK components found in animals and fungi, Light blue: Small coiled-coil proteins belonging to the core STRIPAK, White: STRIPAK-associated proteins

STRIPAK orthologs are also found in fruit fly, yeasts, and in filamentous fungi, which are well-established model organisms for molecular investigations (Table 1). Many studies show that STRIPAK components interact with kinase cascades, regulate development and apoptosis (Ashton-Beaucage *et al.*, 2014, Chen *et al.*, 2002, Deng *et al.*, 2016, Dettmann *et al.*, 2013, Lu *et al.*, 2004, Ribeiro *et al.*, 2010). Thus, the STRIPAK complex is involved in various signaling pathways, which

also connects STRIPAK components to human diseases and cancer (Hwang & Pallas, 2014, Shi *et al.*, 2016). Understanding the molecular interaction of STRIPAK components and their action in signaling pathways will help to understand disease progression and development of adequate treatment for cancer patients and patients suffering from neuronal diseases.

### 1.1 Components of mammalian STRIPAK complex

#### 1.1.1 Striatins

Striatins are highly conserved in eukaryotes like metazoa and fungi but not in prokaryotes and plants. In general, striatins are involved in cellular signaling, motor function, and vesicular trafficking (Benoist *et al.*, 2006). In mammals, striatin, S/G<sub>2</sub> nuclear autoantigen (SG2NA), and zinedin belong to the striatin family (Castets *et al.*, 1996, Castets *et al.*, 2000, Muro *et al.*, 1995). The first striatin, consisting of 780 amino acids (AA) was identified in the striatum and in motor neurons in the rat brain (Castets *et al.*, 1996). SG2NA was identified as a tumor antigen and at least two SG2NA isoforms are known, SG2NA $\alpha$  containing 713 AAs and SG2NA $\beta$  consisting of 797 AAs (Castets *et al.*, 2000, Muro *et al.*, 1995). However, 6 SG2NA splice variants were described, which are expressed in different developmental stages and are tissue specific (Jain *et al.*, 2015, Sanghamitra *et al.*, 2008). Zinedin was identified by TBLASTN using the full-length striatin sequence (Castets *et al.*, 2000) and localizes in the somato-dendritic compartment of hippocampal neurons and dendritic spines (Benoist *et al.*, 2008).

The three mammalian striatins are characterized by a caveolin-binding site, a CC motif, a Ca<sup>2+</sup>-calmodulin-binding site, and 7 WD40 repeats (Baillat *et al.*, 2001, Gaillard *et al.*, 2006, Gaillard *et al.*, 2001) (Figure 2). The consensus sequence of caveolin-binding motif is  $\Phi$ xxxx $\Phi$ xx $\Phi$ , where x represents a random amino acid and  $\Phi$  represents an aromatic amino acid (Couet *et al.*, 1997). Caveolins associate with caveolae, which are cell surface invaginations (Parton & Simons, 2007, Simons & Toomre, 2000, Boscher & Nabi, 2012). As a lipid raft protein, caveolin-1 (Cav-1) is enriched in the post-synaptic density (PSD) of post-synaptic compartments of hippocampal neurons and associates with signaling proteins, for example with Ras, G $\alpha$ , eNOS and tyrosin kinases (García-Cardena *et al.*, 1997, Li *et al.*, 1996, Li *et al.*, 1995, Petralia *et al.*, 2003, Song *et al.*, 1996).

## Introduction

Striatin, SG2NA and zinedin bind to caveolin and thus can associate with membrane microdomains (Gaillard *et al.*, 2001).

**Figure 2: Domains in the mammalian striatin family**

Structure of striatin, zinedin and for the isoform SG2Na $\beta$  is presented. The length of the corresponding proteins is given in the number of amino acids (AA). CV: caveolin-binding domain, CC: coiled-coil domain, CaM: calmodulin-binding domain, WD: tryptophan-aspartic acid repeats. The domains are indicated as predicted but not experimentally verified. Accession numbers: O55106 (*Mus musculus*, striatin), Q9NRL3 (*Homo sapiens*, zinedin), Q13033 (*H. sapiens*, SG2Na $\beta$ ); Modified according to Pöggeler & Kück, 2004.

Striatin family members are able to oligomerize or heteromerize via their CC domain (Gaillard *et al.*, 2006). CC domains are characterized by a heptad pattern *abcdefg*, where *a* and *d* represent hydrophobic amino acids and *b*, *c* and *e-g* represent polar amino acids (Hodges *et al.*, 1973, McLachlan & Stewart, 1975, Cohen & Parry, 1990). In scaffolding proteins, CC domains, which are amphiphilic alpha-helices form a supercoil (Gonzalez *et al.*, 1996, Kammerer, 1997, Lupas, 1996, Yu, 2002).

The CC domain of striatins is contiguous with a basic amphiphilic calmodulin (CaM) -binding site. CaM is a 17 kDa protein, which binds Ca<sup>2+</sup> through its EF-hand type helix-loop-helix motifs. The C-terminal calcium-binding lobe is connected via a flexible helix with the N-terminal lobe (Hoeflich & Ikura, 2002). Striatins interact with CaM in a Ca<sup>2+</sup> dependent manner (Castets *et al.*, 1996, Castets *et al.*, 2000, Moreno *et al.*, 2000, Bartoli *et al.*, 1998). CaM-binding might change striatin conformation, which is influenced by Ca<sup>2+</sup> concentration and thus regulates the subcellular localization of striatins (Gaillard *et al.*, 2001). Deletion of the CaM-binding domain in human striatin results in increased binding of the GCKIII kinases mammalian STE20-like protein kinase 3 and 4 (MST3 and MST4) to striatin (Gordon *et al.*, 2011). Taken together, it is possible that striatins act as calcium sensors in response to changes in Ca<sup>2+</sup> concentration (Benoist *et al.*, 2006).

## Introduction

The C-terminal region of striatins is composed of a WD repeat, whereas W represents tryptophan and D represents aspartic acid (Figure 2). The N-terminal region of the WD repeat is characterized by a variable region with 6-96 amino acids followed by a conserved repeat region. The conserved repeats, which are about 40 amino acids long, contain glycine (G) and histidine (H) at the N-terminal region and WD at the C-terminal region (Neer *et al.*, 1994). WD repeats were originally identified in the  $\beta$ -subunit of heterotrimeric GTP-binding proteins, which are involved in signal transduction across the plasma membrane (Fong *et al.*, 1986). The propeller-like structure of WD repeats brings proteins together and serves as a basis for protein-protein interactions (Hwang & Pallas, 2014, Lambright *et al.*, 1996, Sondek *et al.*, 1996). Deletion of striatin WD repeats reduces MOB3 binding to striatin (Gordon *et al.*, 2011). Also, WD repeats of mammalian striatin are important for binding to the armadillo repeat domain (ARM) of the adenomatous polyposis coli (APC) protein. APC is expressed in epithelial and fetal cells and functions as multifunctional tumor suppressor that negatively regulates Wnt signaling (Breitman *et al.*, 2008, Midgley *et al.*, 1997). Wnt signaling acts on cell survival, proliferation and differentiation during development (Coudreuse & Korswagen, 2007, Logan, 2004, Moon *et al.*, 2004, Nelson & Nusse, 2004).

**Striatins are thought to act as scaffolds to bring other proteins together in the STRIPAK complex.**

### 1.1.2 PP2A

Phosphorylation is required to inhibit or to activate certain signaling pathways influencing processes like sexual development and proliferation (Farrell, 2014, Grallert *et al.*, 2015). Protein phosphatase 2 A is a ubiquitously expressed serine/threonine phosphatase, which is connected to cancer, regulates the cell cycle and microtubule dynamics, and plays a role in apoptosis (Baysal *et al.*, 1998, Wang *et al.*, 1998, Wera *et al.*, 1995, Ruvolo *et al.*, 1999, Santoro *et al.*, 1998, Nunbhakdi-Craig *et al.*, 2007). According to Ruediger *et al.* (1991) up to 0.3-1% of the total protein content of a mammalian cell is PP2A.

In mammals, PP2A is a heterotrimeric protein composed of the scaffolding subunit PP2AA (65 kDa), a catalytic subunit PP2Ac (36 kDa) and regulatory subunits PP2AB. The PP2AA subunit consists of two isoforms PP2A $\alpha$  and PP2A $\beta$  that share 85% sequence identity (da Cruz e Silva & Cohen, 1987, Hemmings *et al.*, 1990). Furthermore, PP2AA is characterized by 15 huntingtin-elongation-A

## Introduction

subunit-IOR (HEAT) repeats, which form a horseshoe-like scaffold for protein-protein interactions (Cho & Xu, 2007). PP2AA and PP2Ac form a core complex, which associates with regulatory B subunits (Janssens & Goris, 2001, Janssens *et al.*, 2008). For the catalytic subunit PP2Ac two isoforms are known, PP2Ac $\alpha$  and PP2Ac $\beta$ , with highest mRNA abundance in brain and heart tissue (Khew-Goodall & Hemmings, 1988). PP2Ac $\alpha$  and PP2Ac $\beta$  are encoded by two different genes (Jones *et al.*, 1993). PP2Ac $\alpha$  has a 7-10 fold stronger promoter than PP2Ac $\beta$  and is 10-fold more abundant than PP2Ac $\beta$  (Khew-Goodall *et al.*, 1991).

Of the regulatory B subunits four types exist (B, B', B'' and B'''), which are required for the recruitment of substrates and determine the subcellular localization of proteins associated with PP2A (Goudreault *et al.*, 2009). It was shown that striatin and SG2NA are regulatory B''' subunits interacting with PP2AA and PP2Ac without the presence of other B subunits (Kean *et al.*, 2011, Moreno *et al.*, 2000). Also, striatin and SG2NA seem to be targets of PP2A because inhibition of PP2A with okadaic acid resulted in increased phosphorylation of striatin and SG2NA (Moreno *et al.*, 2000).

**The protein phosphatase PP2A is regulated by B subunits and is involved in cell cycle, microtubule dynamics and apoptosis.**

### 1.1.3 STRIP1/2

Striatin-interacting proteins 1 and 2 (STRIP1/2), also called FAM40A/FAM40B interact with striatin and mutually exclusively with SLMAP or CTTNBP2/NL (Goudreault *et al.*, 2009) (Figure 1). STRIP1 localizes to the Golgi and depletion of STRIP1 in HeLa cells results in increased DNA content and abnormally shaped or fragmented nuclei (Frost *et al.*, 2012). Also, SLMAP, which was localized to the nuclear envelope and to membranous material around the mitotic spindle interacts with STRIP1 (Frost *et al.*, 2012). Frost *et al.* (2012) suggested that STRIP1 connects the Golgi and centrosomes and is required for centrosome duplication or spindle assembly.

In prostate carcinoma cells depletion of STRIP1 negatively affects cell spreading and results in increased F-actin in the cell periphery (Bai *et al.*, 2011). Whereas, loss of STRIP2 leads to reduced cell-cell adhesion in HeLa cells (Bai *et al.*, 2011). Taken together, STRIP1/2 might be important for

cytoskeleton organization and function (Hwang & Pallas, 2014). However, STRIP1/2 are not further characterized in mammals.

**STRIP1/2 together with SLMAP bridge the Golgi, the nuclear envelope, and the centrosome and have a role in mitosis.**

### 1.1.4 SLMAP/TRAF3IP3

Sarcolemmal membrane-associated protein (SLMAP) was found to be a tail-anchored membrane protein in cardiac muscle cells (Wigle *et al.*, 1997). It was postulated that 12 possible splice variants of SLMAP might exist and that they are tissue and development specifically expressed (Wielowieyski *et al.*, 2000, Guzzo *et al.*, 2005, Wigle *et al.*, 1997).

In addition to the C-terminal trans-membrane domain (TM), SLMAP contains a forkhead-associated (FHA) domain in the N-terminal region. The FHA domain was shown to be important for interaction with the hippo kinases mammalian STE20-like protein kinase 1 (MST1) and 2 (MST2). SLMAP and MST1/2 interact in a phosphorylation-dependent manner. Moreover, the SLMAP-MST1/2 interaction connects the STRIPAK to hippo signaling (Couzens *et al.*, 2013). SLMAP contains a central coiled-coil region, which is required for SLMAP homo-oligomerization (Guzzo *et al.*, 2005, Guzzo *et al.*, 2004b, Wigle *et al.*, 1997).

Alternative splicing generates SLMAPs with one TM domain, which can be either TM1 or TM2. Thus, alternative splicing makes SLMAPs more versatile and defines subcellular targeting (Byers *et al.*, 2009, Guzzo *et al.*, 2005, Wielowieyski *et al.*, 2000).

SLMAP localizes to centrosomes, is important for cell growth, embryonic myoblast fusion and controls the cell cycle (Guzzo *et al.*, 2004a, Guzzo *et al.*, 2004b). It was also reported to be localized at the ER, the nuclear envelope and mitochondria (Byers *et al.*, 2009, Frost *et al.*, 2012, Guzzo *et al.*, 2005, Guzzo *et al.*, 2004b, Wigle *et al.*, 1997).

Like striatin, SLMAP is a component of the STRIPAK complex (Table 1) and defects in the corresponding genes result in cardiac failure because it is involved in excitation-contraction coupling in cardiomyocytes (Guzzo *et al.*, 2005, Ishikawa *et al.*, 2012, Meurs *et al.*, 2010, Nader *et al.*, 2012).

A protein related to SLMAP is tumor necrosis factor receptor-associated factor 3 interacting protein 3 (TRAF3IP3) (Goudreault *et al.*, 2009) (Figure 1, Table 1). Although, SLMAP and TRAF3IP3 share

## Introduction

only 22% sequence identity Goudreault *et al.* (2009) showed that TRAF3IP3 interacts with striatins, MOB3, STRIP1/2, SLMAP, FGFR1OP2 and SIKE. Neither a FHA nor a TM domain were predicted for TRAF3IP3 but CC regions were predicted for both proteins, SLMAP and TRAF3IP3 (Dadgostar *et al.*, 2003, Goudreault *et al.*, 2009). It was assumed that TRAF3IP3 is either posttranslationally modified or alternatively spliced (Dadgostar *et al.*, 2003).

In mammals, the tumor necrosis factor receptor-associated factor 3 (TRAF3) and its associated protein TRAF3IP3 activate c-Jun N-terminal kinase (JNK) signaling (Dadgostar *et al.*, 2003). TRAF3 also activates nuclear factor- $\kappa$ B (NF- $\kappa$ B), an inducible transcription factor, which allows rapid and transient gene expression (Bista *et al.*, 2010, Hayden & Ghosh, 2012). NF- $\kappa$ B in mammals induces genes involved in immune and stress response, development, proliferation, differentiation and apoptosis (Baeuerle P. A. & Henkel, 1994, Hayden *et al.*, 2006).

**SLMAP/TRAF3IP3 are STRIPAK complex proteins, which are involved in cell growth, embryonic myoblast fusion, regulation of the cell cycle and development, proliferation, differentiation and apoptosis, respectively.**

### 1.1.5 CTTNBP2/CTTNBP2NL

The cortactin-binding protein 2 and the CTTNBP2 N-terminal like (CTTNBP2/CTTNBP2NL) proteins are part of the mammalian STRIPAK sub complex II (Figure 1, Table 1) (Goudreault *et al.*, 2009). CTTNBP2 is predicted to be 181 kDa in size but also a homolog CTTNBP2NL with a predicted molecular weight of 70 kDa exists in humans. For both proteins an N-terminal CC region was predicted but an ankyrin-repeat motif only for CTTNBP2 (Li *et al.*, 2006, Ohoka & Takai, 1998). CTTNBP2 was shown to be specifically expressed in brain neurons and very likely involved in neuronal development because defects in CTTNBP2 cause autism spectrum disorders (Ohoka & Takai, 1998, Cheung *et al.*, 2001, Iossifov *et al.*, 2012). CTTNBP2 contains a C-terminal proline-rich region required for interaction with the SH3 domain of cortactin (cortical actin-binding protein) (Ohoka & Takai, 1998). In mammals, the STRIPAK was connected to mitogen-activated protein kinase (MAPK)/extracellular signal-regulated kinase (ERK)- signaling and ERK can phosphorylate cortactin (Campbell *et al.*, 1999, Huang *et al.*, 1998, Huang *et al.*, 1997, Shi *et al.*, 2016).

## Introduction

Cortactin is a regulator of the actin cytoskeleton and interacts with F-actin, which regulates the morphology of dendritic spines in the central nervous system (Penzes & Cahill, 2012, Wu & Parsons, 1993). In sum, CTTNBP2 might affect cortactin phosphorylation and be required for F-actin polymerization (Chen & Hsueh, 2012, Goudreault *et al.*, 2009). However, while CTTNBP2 was identified as STRIPAK component no cortactin was pulled down with STRIPAK complex components (Goudreault *et al.*, 2009).

**CTTNBP2/CTTNBP2NL are part of the mammalian STRIPAK sub complex II and are connected to phosphorylation as well as to regulation of the actin cytoskeleton in neuronal cells.**

### 1.1.6 MOB3 (phocein)

The monopolar spindle one binder 3 (MOB3) protein is a component of the STRIPAK complex and contains a conserved MOB domain (Goudreault *et al.*, 2009, Stavridi *et al.*, 2003, Vitulo *et al.*, 2007). Humans, encode 7 MOB proteins, which are characterized by the 180-200 AA long MOB domain (Chow *et al.*, 2010, Goudreault *et al.*, 2009, Luca & Winey, 1998, Ponchon *et al.*, 2004, Stavridi *et al.*, 2003, Vitulo *et al.*, 2007). Stavridi *et al.* (2003) assumed that the negatively charged surface potential of MOB1 might be required to interact with kinases containing conserved basic regions and thus activates kinases electrostatically.

Structural parts of the MOB domain are partially conserved in MOB3. However, MOB3 is the most divergent clade within the MOB family and it was assumed that MOB3 has another function than the other MOB proteins (Stavridi *et al.*, 2003, Vitulo *et al.*, 2007). The STRIPAK complex component MOB3 is a 225 AA protein and localizes to the cytosol, to membranes and the Golgi. It was localized to somato-dendritic compartments and was shown to interact with striatin, SG2NA and zinedin (Baillat *et al.*, 2001).

MOB3 contains a region homologous to the small chain signature of  $\sigma$  subunits of clathrin adaptor protein (AP) complexes (Baillat *et al.*, 2001). The AP complexes consist of two large subunits, one medium subunit and one small subunit, where the small  $\sigma$  subunit stabilizes the AP complex mediating the formation of vesicles as well as selective packing of the cargoes (Collins *et al.*, 2002, Kirchhausen, 1999, Park & Guo, 2014, Schmid, 1997) The adaptor complexes AP-1, AP-2 and AP-3 are involved in clathrin-mediated vesicular traffic and endocytosis. Clathrin-mediated endocytosis

## Introduction

is not only required for nutrient uptake but also required to remove receptors, integral proteins or lipids from the plasma membrane. The AP-1 complex is recruited to *trans*-Golgi coated vesicles whereas the AP-2 complex associates with plasma membrane coated vesicles (Keen, 1990, Robinson, 1992, Park & Guo, 2014). While, the AP-3 complex is involved in transport from *trans*-Golgi to lysosomes (Gu *et al.*, 2001, Le Borgne *et al.*, 1998).

MOB3 was also shown to interact with epidermal growth factor receptor substrate 15 (EPS15) and nucleoside-diphosphate kinase NDPK (Baillat *et al.*, 2002). EPS15 interacts with AP-2 and is involved in clathrin-mediated endocytosis (Benmerah *et al.*, 1996). NDPK interacts with dynamin I mediating the abscission of vesicles from plasma membranes (Antonny *et al.*, 2016, Baillat *et al.*, 2002, Ferguson & De Camilli, 2012).

The secretion blocking agent brefeldin A (BFA) inhibits small G proteins of the ADP-ribosylation factor (Arf) family, which organize vesicular trafficking (Donaldson *et al.*, 1992). Localization of MOB3 and SG2NA in rat neurons was altered upon exposure to BFA. Thus, interaction of MOB3 with Eps15 or NDPK and altered localization of MOB3 upon BFA treatment suggests that MOB3 is involved in vesicular traffic (Baillat *et al.*, 2002).

**MOB3 interacts with striatins and is thought to be involved in vesicular transport.**

### 1.1.7 Germinal center kinases and CCM3

Germinal center kinases (GCK) are regulators of cell growth, apoptosis, neuronal differentiation, polarization, migration, cell growth and stress response (Delpire, 2009, Sugden *et al.*, 2013). The STRIPAK complex in mammals contains four possible serine/threonine kinases, MST4, MST3 (STK24), serine/threonine kinase 25 (STK25 also called SOK1/YSK1), which belong to the germinal center kinase III (GCKIII) subfamily and misshapen/Nck-interacting kinase (NIK)-related kinase 1 (MINK1), which belongs to the GCKIV subfamily (Gordon *et al.*, 2011, Goudreault *et al.*, 2009, Hyodo *et al.*, 2012, Kean *et al.*, 2011) (Table 1). All four kinases contain an N-terminal catalytic domain but MINK1 additionally contains a citron homology domain (Delpire, 2009).

MST4, MST3 and STK25 interact with cerebral cavernous malformation 3 (CCM3), which also associates with the STRIPAK complex (Fidalgo *et al.*, 2010, Goudreault *et al.*, 2009) (Figure 1).

### 1.1.7.1 MST3

MST3 contains a nuclear export and localization signal. Cleavage of MST3 by caspase activates the kinase, which translocates to the nucleus and results in induction of apoptosis. Four striatin point mutants were unable to bind PP2A, which resulted in hyperphosphorylated and active MST3. Hence, PP2A was shown to be a negative regulator of MST3 (Gordon *et al.*, 2011). Also, SG2NA was suggested to recruit PP2A and to inhibit MST3 activation suppressing apoptosis (Chen *et al.*, 2014).

### 1.1.7.2 MST4 and STK25

The programmed cell death 10 (*PDCD10*) gene product CCM3 is connected to apoptosis and tumor progression. Mutations in the *PDCD10* gene result in cerebral cavernous malformations (Ma *et al.*, 2007). It was shown that CCM3 increases MST4 activity inducing the MAPK/ERK pathway stimulating cell growth (Ma *et al.*, 2007). Further, MST4 was found in a trimeric complex with SG2NA and CCM3, which recruits MST4 to the STRIPAK (Kean *et al.*, 2011).

STK25 has a role in neuronal migration, is activated by oxidative stress and can induce apoptosis (Matsuki *et al.*, 2013, Pombo *et al.*, 1996, Pombo *et al.*, 1997, Zhang *et al.*, 2014). CCM3 interacts with STK25 to regulate MAP kinase/ERK activity under oxidative stress (Zhang *et al.*, 2012). STK25, like MST3, can enter the nucleus to induce cell death (Nogueira *et al.*, 2008).

### 1.1.7.3 MINK

MINK1 is abundant in the brain and is upregulated during postnatal cerebral development. It is an activator of the JNK pathway but not of the MAP kinase /ERK pathway (Dan *et al.*, 2000). Zinedin together with PP2A was shown to deactivate MINK1 by dephosphorylation (Hyodo *et al.*, 2012). Phosphorylated and catalytic active MINK1 is found in mitosis whereas PP2A is inhibited during mitosis (Wurzenberger & Gerlich, 2011). Thus, inactivation of MINK1 through interaction with zinedin and PP2A might regulate abscission in the last step of cytokinesis (Hyodo *et al.*, 2012).

**The GCKs MST3, MST4, STK25 and MINK, which control cellular processes like cell differentiation, cytokinesis, and apoptosis associate with the STRIPAK complex in mammals.**

### 1.1.8 SIKE/FGFR1OP2

Two small coiled-coil proteins, suppressor of IKK $\epsilon$  (SIKE) and fibroblast growth factor receptor 1 oncogene partner 2 (FGFR1OP2), were identified in the mammalian STRIPAK sub-complex I (Table 1). SIKE and FGFR1OP2 are predicted to contain 3 and 4 CC domains, respectively (Marion *et al.*, 2013, Lin *et al.*, 2010, Grand *et al.*, 2004). The sequences of SIKE and FGFR1OP2 share 56% identity but SIKE contains additionally 6 TANK-binding kinase 1 phosphorylation sites in its C-terminal region (Marion *et al.*, 2013).

#### 1.1.8.1 SIKE

Human SIKE is a physiological suppressor of the serine/threonine-protein kinases IKK $\epsilon$  and TANK-binding kinase 1 (TBK1) that play important roles in regulating immune response via transcription factors belonging to the interferon regulatory factor family and the NF- $\kappa$ B family, which is involved in cell survival, development and proliferation (Hayden & Ghosh, 2012, Huang *et al.*, 2005a).

SIKE is also a negative regulator of pathological cardiac hypertrophy because SIKE interacts with TBK1 and inhibits the TBK1-RAC- $\alpha$  serine/threonine-protein kinase AKT (AK strain transforming) pathway (Deng *et al.*, 2016). However, it is not clear if SIKE connects immune response or the AKT pathway with the STRIPAK complex or if it acts independently of the STRIPAK (Hwang & Pallas, 2014).

#### 1.1.8.2 FGFR1OP2

The wound inducible transcript-3.0 (wit-3.0) encodes the SIKE-related protein FGFR1OP2 and was identified in cDNA from an oral wound library (Lin *et al.*, 2010). In a 75-year-old male, the wit-3.0 N-terminal domain encoding CC sequence inserted into the fibroblast growth factor receptor 1 (*FGFR1*) gene caused ligand independent dimerization of FGFR1. The dimerization led to T-cell lymphoblastic lymphoma and myelogenous leukemia. Thus, the gene was named *FGFR1* oncogene partner 2 (FGFR1OP2). FGFR1OP2 influences cell migration and is selectively expressed in fibroblasts, which are in contact with cells in the active margin approximation. Overexpression of FGFR1OP2 in oral wound fibroblasts had increased collagen gel contraction ability and thus significantly accelerated skin wound closure with minimum scarring of oral wounds (Lin *et al.*, 2010).

**Despite that SIKE and FGFR1OP2 were identified to be STRIPAK components, their function within the STRIPAK complex is not investigated in mammals.**

## 1.2 STRIPAK-like complexes in yeasts and in *Drosophila melanogaster*

STRIPAK orthologs were also identified in the fission yeast *Schizosaccharomyces pombe* and in the baker's yeast *Saccharomyces cerevisiae*. In *S. pombe*, the STRIPAK complex is called SIN-inhibitory phosphatase complex (SIP) whereas in *S. cerevisiae* the STRIPAK complex is called factor arrest (Far) complex (Table 1). The SIP complex in fission yeast and interaction with other signaling pathways will be explained first. Subsequently, the Far complex in the baker's yeast and crosstalk to other signaling pathways will be elucidated followed by the STRIPAK complex and its signaling interactions in *Drosophila melanogaster*.

### 1.2.1 The SIP-SIN-MOR crosstalk in *S. pombe*

Cytokinesis in the fission yeast is regulated by the septation initiation network (SIN) (Guertin *et al.*, 2002, Krapp & Simanis, 2008, McCollum & Gould, 2001). The polo kinase 1 (Plo1) is one protein that regulates SIN (Tanaka *et al.*, 2001). Loss of *PLO1* function leads to cell arrest in mitosis and cells without septa (Ohkura *et al.*, 1995). To ensure correct cytokinesis, components of the SIN localize asymmetrically to the spinde-pole bodies (SPBs).

The SIN-inhibitory phosphatase (SIP) complex was found to be a weak inhibitor of the SIN, which promotes SIN asymmetry at SPBs and regulates cytokinesis (Singh *et al.*, 2011). In *S. pombe*, the SIP complex indicated in gray in figure 3, is an ortholog of the mammalian STRIPAK complex. *S. pombe* expresses the STRIPAK orthologs, component of SIP complex 3 (Csc3) (striatin), Csc2 (STRIP1/2), protein phosphatase PP2A regulatory subunit A (Paa1), Ppa3 (PP2Ac1) and Csc1 (SLMAP). Furthermore, the small CC protein Csc4 was identified in the STRIPAK complex of *S. pombe* (Singh *et al.*, 2011) (Table 1).

The SIN complex, indicated in blue in figure 3, contains three kinases: the cyclin-dependent kinase cell division cycle 7 (Cdc7), the GC kinase septum initiation defective 1 (Sid1) and the nuclear dbf2-related (NDR) kinase Sid2. The SIN complex also contains the small GTPase septum promoting GTPase 1 (Spg1), two scaffold proteins Cdc11 and Sid4, which bind via pombe pole component 89 (Ppc89) to SPBs and the adaptor proteins Cdc14 and Mob1. The scaffold protein Sid4 interacts with Ppc89 and connects the SIN to SPBs (Rosenberg *et al.*, 2006). During interphase GTPase Spg1 and the GAP proteins Cdc16 and Byr4 are located on the SPBs to keep Spg1 inactive but are removed during metaphase and allow binding of Cdc7 to SPBs (Fankhauser & Simanis, 1994).

## Introduction

**Figure 3: SIP-SIN-MOR crosstalk regulates cell growth and cell duplication in *S. pombe***

The SIN-inhibitory phosphatase (SIP) complex is suggested to negatively regulate the septation initiation network (SIN) because mutants with nonfunctional SIP genes show a hyperactive SIN phenotype with premature septum formation and cells without nuclei. In general, the polo kinase Plo1 is an activator of the SIN, which regulates actomyosin ring formation and cytokinesis in *S. pombe*. The morphogenesis Orb6 network (MOR) pathway is negatively regulated by the SIN during mitosis. Sid2 blocks the interaction of Nak1 and the scaffolding protein Mor2 to prevent polarized growth during mitosis. However, SIN can also induce MOR during interphase. Cdc7 via Sid1 activates Nak1 to promote polarized growth. MOR also negatively regulates SIN via Nak1, which persists on SPBs to prevent premature SIN activation. Dash lines: not completely described interaction/pathway or pathway simplified. Continuous lines: direct interactions. Modified from Krapp & Simanis (2008) and Gupta & McCollum (2011). Detailed explanation and abbreviations are given in the text.

SIN signaling is transmitted via Cdc7, Sid1-Cdc14 and Sid2-Mob1 to promote actomyosin ring maturation, constriction and septation (Chang & Gould, 2000, Fankhauser & Simanis, 1994, Guertin *et al.*, 2000, Hou *et al.*, 2000, Krapp *et al.*, 2001, Salimova *et al.*, 2000, Sparks *et al.*, 1999) (Figure 3). Loss of SIN genes reduces or prevents septation and leads to multinucleated and elongated cells

whereas a hyperactive SIN leads to premature septum formation and compartments without nuclei (Fankhauser *et al.*, 1993, Fankhauser & Simanis, 1993, Li *et al.*, 2000, Minet *et al.*, 1979, Schmidt *et al.*, 1997). Localization of SIP components Csc1, Csc2, Csc3 and the PP2A regulatory subunit A (Paa1) showed that all four proteins localize to SPBs and Csc2 and Csc3 were additionally localized to the nuclear envelope. Bi- and uni-nucleated cells with defects in septation (two or more septae) were reported when SIP function was abolished. Thus, SIP was shown to be a negative regulator of SIN (Singh *et al.*, 2011). Furthermore, SIN is negatively regulated by the morphogenesis Orb6 network (MOR) indicated in purple in figure 3. The MOR pathway includes the germinal center II (GC) kinase Nak1 with its binding partner the leucine-rich repeat protein Sog2 (Huang *et al.*, 2003). Nak1 activates the NDR kinase Orb6, which interacts with the scaffold protein morphological round 2 (Mor2) and with its coactivator the Mob1-related protein Mob2 (Figure 3). During interphase MOR is required for polarized growth and controls cell morphology. Via Cdc7 and Sid1, Nak1 activity is upregulated (Kanai *et al.*, 2005). It was suggested that MOR is inhibited by the SIN during mitosis to prevent actin competition (Gupta & McCollum, 2011). The NDR/LATS family kinase Sid2 of the SIN pathway can phosphorylate Nak1, blocking the Nak1-Mor2 interaction and removing Nak1 from SPBs, which in turn activates SIN. It was concluded that Nak1 might reside on SPBs to prevent premature SIN activation (Gupta *et al.*, 2013).

**Taken together, SIN inhibits MOR during mitosis to ensure cell division but also enhances MOR during interphase when polarized cell growth takes place. Moreover, SIP seems to be involved in tight regulation between cell duplication and cell growth.**

### **1.2.2 The Far complex in *Saccharomyces cerevisiae***

#### **1.2.2.1 The Far complex in *S. cerevisiae* is involved in pheromone-mediated cell cycle arrest**

Haploid *S. cerevisiae* cells sense their mating partner via mating pheromones and by a G protein-coupled serpentine receptor leading to the activation of the mitogen-activated protein kinase cascade and cell cycle arrest. The pheromone response is transmitted to facilitate mating and promotes expression of mating-specific genes (Elion, 2001, Leberer *et al.*, 1992, Nomoto *et al.*, 1990, Whiteway *et al.*, 1989).

## Introduction

**Figure 4: Signaling pathways TORC1/2, Far and MEN in *S. cerevisiae***

Schematic representation of the Far complex interacting with signaling pathways target of rapamycin complex 1 (TORC1), TORC2, cell wall integrity (CWI) pathway and mitotic exit network (MEN) in *S. cerevisiae*. Pheromones activate the Fus3/Kss1 mitogen-activated protein kinase cascade. The Far complex is thought to prevent premature recovery from pheromone induced G1 arrest until cells fuse and then enter meiosis. TORC2 signaling acts on the Rho signaling/CWI pathway and actin cytoskeleton polarization via phosphorylation of Slm1 but the Far complex can mediate dephosphorylation of Slm1 and antagonizes actin cytoskeleton polarization. Via Slm1 Far complex also regulates the cell wall integrity pathway. The Far complex negatively regulates TORC1 signaling leading to dephosphorylation of Atg13 which induces autophagy. The Far complex is suggested to interact with the MEN regulating cytokinesis and mitotic exit but the mode of action is unclear. Dash lines: not completely described interaction/pathway or pathway simplified. Continuous lines: direct interactions. Modified from Bardin and Amon (2001), Hergovich *et al.* (2008) Kemp & Sprague (2003), Pracheil *et al.* (2012), Pracheil & Liu (2013). Detailed explanation and abbreviations are given in the text.

## Introduction

In *S. cerevisiae*, the factor arrest (Far) complex was shown to be involved in pheromone-induced G1 cell cycle arrest and shares the orthologs Far8 (striatin), Far9/Far10 (SLMAP) and Far11 (STRIP1/2) with the STRIPAK complex (Goudreault *et al.*, 2009, Kemp & Sprague, 2003, Lai *et al.*, 2011) (Table 1). The phosphatase scaffolding subunit in *S. cerevisiae* is called Tpd3 and interacts with Far11 as well as with the catalytic protein phosphatase subunits Pph3, Pph21, Pph22 (Lisa-Santamaría *et al.*, 2012) (Figure 4, Table 1). Interestingly, the two small cc proteins Far3 and Far7 are present in the Far complex (Kemp & Sprague, 2003, Lai *et al.*, 2011). Far3 interacts with Far7 and Far8 to form a sub complex recruiting Far9 and Far10 to the endoplasmic reticulum (ER) (Pracheil & Liu, 2013).

**Yeasts with mutations in *FAR* genes are resistant to pheromone-induced G1 arrest, thus it was suggested that the Far complex prevents premature recovery from G1 arrest to ensure that mating cells have enough time to fuse before they enter meiosis.**

### 1.2.2.2 The Far complex regulates cell growth, autophagy and actin polarization

The Far complex in *S. cerevisiae* was connected to target of rapamycin complex (TORC) signaling (Lisa) (Figure 4). The TORC1 is composed of the Tor1 kinase, the modulator lethal with sec thirteen 8 (Lst8) protein, the 89-kDa subunit of Tor complex one (Tco98) and the scaffolding protein kontroller of growth 1 (KOG1) and is involved in cell growth and autophagy. On the other hand, the second rapamycin insensitive complex of *S. cerevisiae*, TORC2, is involved in cell cycle-dependent polarization of the actin cytoskeleton (Cybulski & Hall, 2009, Schmelzle & Hall, 2000, Wullschleger *et al.*, 2005) (Figure 4).

Rapamycin treatment leads to TORC1 inhibition, dephosphorylation of Atg13 and, finally to initiation of autophagy. However, dephosphorylation of Atg13 did not take place in *FAR11* deletion mutants, not even when they were treated with rapamycin (Lisa-Santamaría *et al.*, 2012). Far11 might inhibit TORC1 directly or by an alternative way inhibiting the serine/threonine kinase target of rapamycin (Tor1) leading to autophagy (Lisa-Santamaría *et al.*, 2012, Wullschleger *et al.*, 2005). TORC2-deficient mutants have been shown to be lethal but Far deletion mutants suppress the lethal phenotype partially (Pracheil *et al.*, 2012). The TORC2 contains the kinase Tor2, the scaffolding proteins adheres-voraciously-to-target-of-rapamycin-2 protein 1 (Avo1) and 3 (Avo3),

## Introduction

the modulator Lst8 and the adaptor proteins Avo2 and 61-kDa-binding partner of Tor2 (Bit61) (Wullschleger *et al.*, 2005). Depletion of the STRIP1/2 ortholog Far11 in Avo3 mutants suppressed actin polarization defects (Baryshnikova *et al.*, 2010). Thus, the phosphatidylinositol-4-phosphate 5-kinase-binding protein synthetic lethal with Mss4 (multicopy suppressor of Stt4 mutation) 1 (Slm1) is a TORC2 substrate, which is involved in actin cytoskeleton organization and might be dephosphorylated by the Far11-PP2A complex associated with the B'-regulatory subunit rox three suppressor 1 (Rts1) (Pracheil *et al.*, 2012). Thus, it was suggested that the Far complex acts downstream of the TORC2 pathway, negatively regulates TORC2 signaling, and is involved in actin polarization (Baryshnikova *et al.*, 2010, Pracheil *et al.*, 2012) (Figure 4).

TORC2 signaling also activates the Ras homolog 1 (Rho1) GTPase switch. Rho1 multicopy suppressor 2 (Rom2) is the GDP-GTP exchange factor and suppressor of actin 7 (Sac7) the activating protein of Rho1. The Rho1-GTP activated protein kinase C 1 (Pkc1) pathway, which includes also the Pkc1-activated cell wall integrity (CWI) MAP-kinase cascade pathway controls actin distribution and cell wall extension (Levin, 2011) (Figure 4).

The deletion of *ROM2* in TORC2-deficiency mutants leads to loss of actin polarization in these mutants, whereas, the deletion of *FAR11* and *SAC7* results in polarization of the actin cytoskeleton. Thus, it was suggested that Far11 acts downstream of TORC2 but upstream of Rho GTPase signaling mediating phosphorylation of Slm1 (Pracheil *et al.*, 2012) (Figure 4). Nevertheless, it remains unclear if two regulatory B subunits, B' Rts1 and B''' Far8, can associate with PP2A at the same time. It can be speculated that the Far complex exists in parallel to a Far11-PP2A-Rts1 complex and a crosstalk between these complexes might influence TORC1/2 signaling.

**The Far complex regulates TORC1/2 signaling as well as autophagy, actin polymerization and the cell wall integrity pathway.**

### 1.2.2.3 MEN regulates mitotic exit and cytokinesis in *S. cerevisiae*

The SIN in *S. cerevisiae* is called mitotic exit network (MEN). The MEN is a GTPase signaling cascade and is regulated by the spindle-pole body (SPB) localized small GTPase termination of M phase 1 (Tem1), its two component GAP proteins budding uninhibited by benzimidazole 2-byr-four-alike 1 (Bub2-Bfa1) and its putative exchange factor low temperature essential 1 (Lte1). The polo kinase

## Introduction

Cdc5 phosphorylates and inactivates the Bub2-Bfa1 MEN inhibiting complex rendering Tem1 active, thereby initiating MEN signaling. MEN signaling is transmitted through the hippo-related kinase Cdc15 and the serine/threonine kinase dumbbell former 2 (Dbf2), which associates with its adaptor protein Mob1. Cdc15 interacts with the scaffolding protein Nud1 connecting MEN complex proteins with SPBs (Gruneberg *et al.*, 2000) (Figure 4). Therefore, the SIN in *S. pombe* as well as the MEN in *S. cerevisiae* are both connected to SPBs (Figure 3 and Figure 4).

The Dbf2-Mob1 complex phosphorylates the tyrosine protein phosphatase Cdc14, which inactivates mitotic cyclins by dephosphorylation to exit mitosis (Bardin & Amon, 2001, Bosl & Li, Meitinger *et al.*, 2012, Mohl *et al.*, 2009). Both, Cdc15 and Dbf2-Mob1 are involved in actomyosin ring contraction but only Dbf2-Mob1 regulates cytokinesis (Meitinger *et al.*, 2012, Meitinger *et al.*, 2010, Menssen *et al.*, 2001). Crosstalk between the Far complex and the MEN signaling in *S. cerevisiae* is suggested but the mode of action is unclear.

**In *S. pombe*, the SIN is negatively regulated by the STRIPAK ortholog SIP, thus it is possible that the Far complex also regulates mitotic exit and cytokinesis through MEN signaling in *S. cerevisiae*.**

### 1.2.3 STRIPAK complex in *Drosophila melanogaster*

The STRIPAK in *Drosophila melanogaster* (dSTRIPAK) is involved in development, more precisely, in embryonic dorsal closure and apoptosis of cells in wing imaginal disks (Chen *et al.*, 2002). The dSTRIPAK contains the striatin ortholog Cka, the phosphatase scaffolding subunit Pp2A-29B and the phosphatase catalytic subunit Mts as well as the STRIP1/2 ortholog CG11526, the SLMAP ortholog CG17494, the CTTNBP2 ortholog CG10915, the kinase activator Mob4, the kinase GCKIII and the CCM3 ortholog CG5073 (Ashton-Beaucage *et al.*, 2014, Ribeiro *et al.*, 2010) (Figure 5, Table 1).

#### 1.2.3.1 Hippo signaling in *D. melanogaster*

In *D. melanogaster* the dSTRIPAK complex inhibits Hippo signaling (Ribeiro *et al.*, 2010). The *Drosophila* ortholog of FGFR1OP2, named FGOP2, associates with the striatin ortholog Cka negatively regulating Hippo signaling to prevent restriction of tissue growth and apoptosis during development (Ribeiro *et al.*, 2010). Moreover, Hippo signaling regulates F-actin polymerization and migration (Lucas *et al.*, 2013).

## Introduction

**Figure 5: The dSTRIPAK inhibits Hippo signaling in *D. melanogaster***

Graphical representation of dSTRIPAK interaction with Hippo, dJnk and Ras-Raf-MAPK/ERK signaling. In the hippo pathway active Hpo kinase inhibits the transcription activator Yorkie (Yki). Cka and FGOP2 components of the dSTRIPAK negatively regulate hippo signaling during development. Yki translocates to the nucleus and together with Sd promotes *rho1* transcription. Rho1 activates dJnk signaling. Cka associates with the kinases Hep and Bsk and brings the transcription factor AP1, composed of Kay (D-Fos) and Jra (DJun), into the nucleus. AP1 promotes transcription of target genes to ensure dorsal closure and regulates apoptosis in wing imaginal disks. It is unclear whether Cka acts together or independently of the dSTRIPAK complex to regulate dJnk signaling positively. Cka was also shown to activate Ras-Raf-MAPK/ERK signaling. Ras-Raf-MAPK/ERK signaling regulates cell growth, differentiation, proliferation, inhibition apoptosis and cell migration. Furthermore, Cka, the SLMAP ortholog CG17494, FGOP2, the STRIP ortholog CG11526 and Mob4 were identified to act upstream of Raf. Some parts of the figure are modified according to Zhao *et al.* (2011), Frey *et al.* (2015b), Ríos-Barrera and Riesgo-Escovar (2013) and Ashton-Beaucage *et al.* (2014).

## Introduction

The Hippo pathway is a kinase cascade very similar to the yeast SIN/MEN pathways and controls organ size by suppressing cell proliferation (Hergovich & Hemmings, 2012). The serine/threonine kinase Hippo (Hpo) interacts with the scaffold protein Salvador (Sav) and activates the Dbf2-related kinase Warts (Wts) interacting with Mob as tumor suppressor (Mats). The active Hippo pathway results in phosphorylation and inhibition of the transcriptional activator Yorkie (Yki). In contrast, Yki is dephosphorylated and active when the Hpo pathway is inhibited. Dephosphorylated Yki enters the nucleus, interacts with the transcription factor Scalloped (Sd), activates target genes to promote cell growth, and inhibits apoptosis (Huang *et al.*, 2005b, Kango-Singh & Singh, 2009, Lai *et al.*, 2005, Tapon *et al.*, 2002) (Figure 5).

Unfortunately, is not clear if the Hippo pathway in *D. melanogaster* controls mitotic exit and cytokinesis.

**Taken together, the dSTRIPAK prevents Hpo activation promoting growth during development. However, the role of the dSTRIPAK in actin polymerization, mitotic exit and cytokinesis in *D. melanogaster* remains to be examined.**

### 1.2.3.2 Cka in the Jun-N-terminal kinase pathway in *D. melanogaster*

The striatin ortholog Cka was identified as positive regulator of the Jun-N-terminal kinase (dJnk) pathway. Cka is required in epithelial sheet movement during embryonic dorsal closure and at later developmental stages to regulate apoptosis in wing imaginal wings (Chen *et al.*, 2002).

Loss of function of the Ste20-related kinase, MiSSHapen (Msn) leads to a dorsal open phenotype in *D. melanogaster* and is similar to embryos lacking dJnk components. Msn, the ortholog of mammalian MINK1 kinase, was shown to function upstream of Hemipterous kinase (Hep), which is part of the dJnk signaling pathway (Su *et al.*, 1998). Cka associates with the serine/threonine kinases Hep and Basket (Bsk). Jun-related antigen (Jra (D-Jun)) and Kayak (Kay (D-Fos)) dimerize to form the transcription factor AP1. Finally, Cka together with Bsk and AP1 translocate to the nucleus (Figure 5). Mutations in *kay*, *jra* and *cka* genes cause a dorsal open phenotype. Likewise, Jra and Cka control epithelial sheet movement during dorsal closure through AP-1 mediated transcription (Chen *et al.*, 2002).

## Introduction

However, no other dSTRIPAK proteins than Cka were shown to interact with kinases of the dJnk pathway, thus, it is possible that the dSTRIPAK complex negatively regulates Hippo signaling but Cka acts in a dSTRIPAK-independent way with the dJnk pathway. It is also worth to think about the dSTRIPAK complex both as hippo signaling regulator and as courier to deliver Cka for interaction with the kinases Bsk and Hep.

In *D. melanogaster*, *rho1* was identified as Yki/Sd target. Again, the dSTRIPAK was described to inhibit Hippo signaling (Ribeiro *et al.*, 2010) and the small GTPase dRho1 activates dJnk when Hippo signaling is lost (Ma *et al.*, 2015). Interestingly, the Far complex in *S. cerevisiae* was also connected to Rho-signaling. Far is suggested to regulate Rho-CWI signaling in, which Rho1 activates Pkc1 in the cell wall integrity pathway (Levin, 2005). Similar, dSTRIPAK might modulate CWI pathway in *D. melanogaster* via Yki-Sd-dRho1. Consistent with the results of Ma *et al.*, (2015) deletion of dSTRIPAK components renders Hippo signaling active, which suppresses dJnk activity via Yki1, Sd and dRho1 and results in suppression of the hpo overgrowth phenotype (Ribeiro *et al.*, 2010) (Figure 5).

**In sum, Cka is a component of the dSTRIPAK and associates with the protein phosphatase Pp2A-29B and the SLMAP ortholog CG17494. *D. melanogaster* STRIPAK regulates growth during development, dorsal closure and apoptosis in wing imaginal disks and was connected to the Hippo and dJnk signaling pathways.**

### **1.2.3.3 The dSTRIPAK activates the Ras-Raf-MAPK/ERK pathway**

In addition to its involvement in Hippo signaling and the dJnk pathway, the dSTRIPAK acts as positive regulator of Ras-Raf-MAPK/ERK signaling. The Ras-Raf-MAPK/ERK signaling regulates cell growth, differentiation, migration and proliferation as well as inhibition of apoptosis (McCubrey *et al.*, 2007, Santarpia *et al.*, 2012) (Figure 5). Cka was shown to activate Ras-Raf-MAPK/ERK signaling and the dSTRIPAK components Cka, GCKIII and Mts were shown to associate with Raf (Friedman & Perrimon, 2006, Horn *et al.*, 2011). The five dSTRIPAK components, Cka, the SLMAP ortholog CG17494, FGOP2, the STRIP ortholog CG11526 and Mob4 act upstream of Raf positively regulating Raf (Ashton-Beaucage *et al.*, 2014). In the same study, the authors supposed, that the dSTRIPAK

might facilitate PP2A binding to Raf. Unfortunately, the authors did not further investigate protein-protein interactions between dSTRIPAK components and Ras-Raf-MAPK/ERK members.

**Taken together, dSTRIPAK in *D. melanogaster* might positively regulate cell growth, differentiation, migration and proliferation as well as inhibition of apoptosis. However, it is not known if like in mammals mutually exclusive dSTRIPAK complexes exist in the fruit fly, which might regulate different signaling pathways.**

### **1.3 *Sordaria macrospora* is a model organism to study fruiting-body development**

This work concentrates on the STRIPAK complex in the eukaryote and multicellular filamentous fungus *S. macrospora*. Next, the model organism *S. macrospora* will be presented followed by the current knowledge about the STRIPAK complex in *S. macrospora* and other filamentous fungi.

Eukaryotic cell biology is studied in various lower eukaryotic model organisms for example yeasts or filamentous fungi. The latter are closer related to mammals than to plants making them interesting models to study molecular mechanisms also found in human cells (Pace, 2009, Van der Klei & Veenhuis, 2006). *S. macrospora* is a filamentous fungus of the phylum Ascomycota, which is naturally found in the dung of herbivores (Esser, 1982). Transformation of mycelium to pear shaped fruiting bodies with various cell types requires complex and tight spatial-temporal regulation of the involved genes (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014). During sexual development 13 different cell types are generated, which are not present in the vegetative mycelium (Lord & Read, 2011). *S. macrospora* is a haploid and self-fertile filamentous fungus and therefore does not need a mating partner to propagate sexually by meiotic ascospores (Lord & Read, 2011, Pöggeler *et al.*, 1997). Thus, recessive mutations of genes that are involved in fruiting-body formation and differentiation can be directly detected. Hence, *S. macrospora* is an excellent model for genetic and microscopic analysis (Lord & Read, 2011, Teichert *et al.*, 2014). Many molecular and genetic methods are well established and the relatively small genome of 40 MB is fully sequenced (Nowrousian *et al.*, 2012). Moreover, *S. macrospora* is not harmful, easy to manipulate and easy to grow under laboratory conditions (Kück *et al.*, 2009).

The life cycle of *S. macrospora* in the laboratory takes 7 days. Sexual development starts at day 2 when the first sexual structures, the ascogonia, are formed. Ascogonia develop into

## Introduction

protoperithecia at day 3-4 and into mature perithecia filled with ascospores at day 6-7 (Teichert *et al.*, 2014) (Figure 6). In the tip of ascogonous hyphae, which emerge from ascogonia two nuclei pair up. These hyphae with two nuclei form a hook-like structure called the crozier. Subsequently, synchronous mitotic division and formation of two septa takes place. The lateral and the basal cell contain one nucleus each whereas the apical cell contains two nuclei, which fuse (karyogamy) followed by meiosis and a post-meiotic mitosis. Finally, the perithecia contain 50-300 asci each containing 8 linearly ordered ascospores, which are discharged through the ostiolum, an apical pore in the perithecium. The ascospores germinate and the life cycle starts again (Engh *et al.*, 2010, Kück *et al.*, 2009, Esser, 1982) (Figure 6).

**Figure 6: The life cycle of *S. macrospora***

Schematic representation of the *S. macrospora* life cycle in a time line. The life cycle starts with a germinating ascospore generating mycelium. From the mycelium, first sexual structures, the ascogonia, are formed at day 2, which develop into pre-fruitlet bodies the protoperithecia at day 3-4. In ascogonous hyphae nuclei pair up followed by mitotic (Mi) and synchronous division followed by septum formation (SF), karyogamy (K) meiosis and postmeiotic mitosis (PM). Mature fruitlet bodies (perithecia) contain 50-300 asci each with 8 linearly ordered ascospores (S), which are discharged through the ostiolum at day 7-8. Modified according to Pöggeler (2000), drawing modified according to H. J. Rathke.

### 1.3.1 The STRIPAK complex in *S. macrospora* regulates sexual development and hyphal fusion

The filamentous ascomycete *S. macrospora* propagates only via sexually formed fruitlet bodies. The process from a two-dimensional mycelium to three-dimensional fruitlet bodies with various cell types requires complex and tight regulation. In the past, many factors needed for the development of fruitlet bodies were identified (Kück *et al.*, 2009, Teichert *et al.*, 2014). In

*S. macrospora*, one multi protein complex involved in this process is the striatin-interacting phosphatase and kinase complex (SmSTRIPAK) (Kück *et al.*, 2016). This complex is of general interest beyond fungal development, since its components are conserved in fungi and animals (Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Engh *et al.*, 2010, Goudreault *et al.*, 2009, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004, Kück *et al.*, 2016). In *S. macrospora*, the scaffolding subunit SmPP2AA of the serine/threonine phosphatase PP2A, interacted in yeast two-hybrid experiments with the striatin ortholog/B'' regulatory subunit protoperithecium mutant 11 (PRO11). Further, SmSTRIPAK core components are the catalytic PP2A subunit, SmPP2Ac1, the STRIP1/2 ortholog PRO22, the SLMAP ortholog PRO45, and the kinase activator SmMOB3 (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Beier *et al.*, 2016). Additionally, the dual-targeted protein glycosylphosphatidylinositol-anchored protein 1 (SmGPI1) and the GCKIII kinases SmKIN3 and SmKIN24 were identified to interact with STRIPAK components of *S. macrospora* (Frey *et al.*, 2015a, Frey *et al.*, 2015b).

### **1.3.2 Striatin orthologs in filamentous fungi control hyphal fusion, sexual development and vegetative growth**

PRO11 is a protein with a predicted molecular mass of 90 kDa. PRO11 is suggested to provide a scaffold for the association of STRIPAK complex proteins (Bloemendal *et al.*, 2012). Like all striatins, PRO11 is characterized by a Ca<sup>2+</sup>-calmodulin-binding site, a CC domain, a putative caveolin-binding site and 7 WD40 repeats (Pöggeler & Kück, 2004). However, caveolin orthologs are not encoded by *S. macrospora* or other filamentous fungi (Nowrousian, 2010, Pöggeler & Kück, 2004).

A nonsense mutation in the *pro11* gene with a STOP codon at the amino-acid position 546 results in a truncated PRO11 protein lacking several WD40 repeats (Pöggeler & Kück, 2004). The corresponding *pro11* strain develops protoperithecia, but is not able to form mature fruiting bodies (perithecia). Likewise, mutation or deletion of *pro11* results in a sterile phenotype, which is devoid of hyphal fusion. Interestingly, striatins are functionally conserved because mouse striatin cDNA complemented the sterile phenotype of *pro11* (Pöggeler & Kück, 2004).

The hyphal anastomosis protein 3 (HAM-3) is part of the STRIPAK complex in the closely related fungus *Neurospora crassa* controlling hyphal fusion and sexual development (Simonin *et al.*, 2010). The *Aspergillus nidulans* striatin ortholog StrA was reported to be important for colony growth,

## Introduction

cleistothecium development and ascosporeogenesis (Wang *et al.*, 2010). A striatin ortholog, which is involved in virulence and sexual mating is also found in *Fusarium verticillioides* and in *Fusarium graminearum* (Shim *et al.*, 2006). The deletion of the striatin orthologous gene *str1* in *Colletotrichum graminicola* results in a defect in hyphal fusion and virulence (Wang *et al.*, 2016).

### Figure 7: The STRIPAK complex in *S. macrospora*

The core STRIPAK complex in *S. macrospora* includes the striatin ortholog PRO11, the STRIP 1/2 ortholog PRO22, the MOB3 (phocein) ortholog SmMOB3, the SLMAP ortholog PRO45, and the protein phosphatase 2 A scaffolding and catalytic subunit SmPP2AA and SmPP2Ac1, respectively. STRIPAK-associated proteins in *S. macrospora* are the dual-targeted protein SmGPI1 and the GCKIII kinases SmKIN3 and SmKIN24. The STRIPAK is involved in septation, was connected to TORC signaling and to the CWI pathway, through SmPP2Ac1 and PRO22 but underlying molecular processes are unknown. Involvement of SmMOB3 in vesicle transport is suggested but was not experimentally verified. Modified according to Bloemendal *et al.* (2012), Beier *et al.* (2016) and Nordziske *et al.* (2015).

### 1.3.3 Fungal MOB3 proteins are involved in hyphal fusion, development and vesicular traffic

In *S. macrospora*, the MOB3 (phocein) ortholog SmMOB3 has N-terminal and C-terminal stretches and thus is three times longer compared to MOB3 (phocein) proteins in animals. SmMOB3 contains a conserved MOB domain and has a predicted molecular mass of 72 kDa. Fungal MOB3 proteins also contain a region, which is homologous to the small chain signature of the  $\sigma$  subunits of clathrin adaptor (AP) complexes and a region homologous to a PxxDY type SH-binding domain (Baillat *et al.*, 2001, Bernhards & Pöggeler, 2011). In general, proteins with these domains are associated with endocytosis (Musacchio *et al.*, 1992, Popova *et al.*, 2013, Verschueren *et al.*, 2015). In mammals,

MOB3 (phocein) associates with NDPK, Eps15 and dynamin and was suggested to be involved in vesicular traffic and clathrin-mediated endocytosis (Baillat *et al.*, 2002, Baillat *et al.*, 2001).

In *S. macrospora*, SmMOB3 interacts with the striatin ortholog PRO11 and is involved in hyphal fusion and sexual development (Bernhards & Pöggeler, 2011). The *in silico* analysis of the SmMOB3 protein indicated that the SmSTRIPAK might be linked to vesicular traffic and endocytosis (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012). The MOB-3 protein in *N. crassa* was also reported to be involved in hyphal fusion and sexual development (Maerz *et al.*, 2009). In *Epichloë festucae*, the MOB3 ortholog MobC is required to maintain the mutualistic symbiotic interaction between the fungus and the cool-season grass *Lolium perenne* and regulates cell-cell fusion and exressoria formation (Green *et al.*, 2016).

### **1.3.4 The fungal STRIP1/2 ortholog and the catalytic PP2ac1 subunit link the fungal STRIPAK to septation and the CWI pathway**

Further STRIPAK components were identified in *S. macrospora*. The PRO11 interaction partner PRO22 (STRIP1/2) is involved in septum formation in ascogonia as well as associates with tubular vacuoles (Bloemendal *et al.*, 2010). PRO22 is a protein with a calculated size of 124 kDa containing three predicted transmembrane domains (Bloemendal *et al.*, 2010). In *N. crassa* the STRIP 1/2 ortholog hyphal anastomosis-2 (HAM-2) was found to be a transmembrane protein required for hyphal fusion and sexual development. Deletion of the *ham-2* gene leads to female sterility, slow growth rate, lack of hyphal fusion, and shortened areal hyphae (Xiang *et al.*, 2002). Roca *et al.* (2005) showed that the *ham-2* gene is required for fusion of conidial anastomosis tubes (CATs) and thus for fusion of conidial germlings. In fluorescence microscopy HAM-2 was localized to the nuclear envelope in *N. crassa* (Dettmann *et al.*, 2013).

Recently, in *S. macrospora* the catalytic PP2A subunit SmPP2Ac1 was identified in a tandem affinity purification coupled with mass spectrometry approach (TAP-MS) using PRO22 as bait (Bloemendal *et al.*, 2012). SmPP2Ac1 is required for phosphatase activity, sexual development and septum formation in ascogonia. Septation was missing in early reproductive structures in *Smpp2ac1* and also in *pro22* deletion mutants (Beier *et al.*, 2016, Bloemendal *et al.*, 2010). In the same study STRIPAK components were connected to TORC signaling and to the cell wall integrity MAP kinase pathway (Beier *et al.*, 2016). Consistently, the studies of Dettmann *et al.* (2013) and Fu *et al.* (2011)

suggested interactions between the STRIPAK and the cell wall integrity MAP kinase pathway in *N. crassa*.

### **1.3.5 The SLMAP ortholog PRO45 is part of the fungal STRIPAK complex in *S. macrospora***

The SLMAP ortholog PRO45 was demonstrated to interact with PRO11 and SmMOB3. PRO45 has a predicted size of 86 kDa and contains a C-terminal transmembrane (TM) domain, a forkhead-associated (FHA) domain in the N-terminal part and two CC regions between the FHA and the TM domain. PRO45 associates with the endoplasmic reticulum (ER), the nuclear envelope and mitochondria (Nordzieke *et al.*, 2015). Fluorescence microscopy showed that the SLMAP ortholog HAM-4 localized to the nuclear envelope in a patchy manner and to the endomembrane system. In cell fractionation assays HAM-4 was present in the nuclear fraction and a minor amount was present in the cytosol/endomembrane fraction (Dettmann *et al.*, 2013). In *N. crassa*, the striatin ortholog HAM-3 and the tail-anchored protein HAM-4 were shown to function together in the NcSTRIPAK complex and influence hyphal fusion and sexual development (Simonin *et al.*, 2010). Simonin *et al.* (2010) showed that *ham-2*, *ham-3* and *ham-4* mutants are reduced in growth rate, have short areal hyphae and an aberrant ascospore development.

### **1.3.6 Fungal STRIPAK-associated proteins SmGPI1 and GCKIII kinases SmKIN3 and SmKIN24**

Interaction between the kinase activator SmMOB3 and the glycosylphosphatidylinositol-anchored protein 1 (SmGPI1) was shown in *S. macrospora*. SmGPI1 is a protein with a calculated molecular mass of 26 kDa containing a secretion signal sequence in the N-terminal part of the protein and a region for GPI-anchor attachment in the C-terminal part of the protein. SmGPI1 is suggested to be a negative regulator of sexual development and localizes to the plasma membrane, cell wall and to mitochondria (Frey *et al.*, 2015a).

The GCKIII kinases SmKIN3 and SmKIN24 were shown to physically interact with PRO11 and might link the SmSTRIPAK complex to a kinase-dependent signaling pathway. SmKIN3 and SmKIN24 have a predicted molecular mass of 74 and 98 kDa, respectively. The catalytic domain of SmKIN3 and SmKIN24 are in the N-terminal regions of the proteins and shows the highest homology to Ste20-like kinase3 serine/threonine-protein kinases. Deletion of SmKIN3 and SmKIN24 results in a septation phenotype in young vegetative hyphae (Frey *et al.*, 2015b). Interestingly, the

developmental protein PRO22 and the catalytic PP2A subunit SmPP2Ac1 are also connected to septation in *S. macrospora* (Beier et al., 2016, Bloemendal et al., 2010). However, the connection between subcellular location and the mode of action of STRIPAK signaling in *S. macrospora* is unclear.

**All in all, orthologs of the STRIPAK that are found in higher eukaryotes are also present in the fungal STRIPAK complex controlling fungal sexual development, hyphal fusion and vegetative growth.**

### 1.4 Aims of this thesis

Filamentous fungi undergo multicellular differentiation during their life cycle and are excellent models to study developmental processes like fruiting-body development (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014).

*S. macrospora* is a non-pathogenic fungus generating three-dimensional fruiting bodies from two dimensional mycelium within 7 days in the laboratory (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014). The fact that *S. macrospora* is homothallic, and self-fertile facilitates detection of recessive mutations (Lord & Read, 2011, Pöggeler *et al.*, 1997). Mutants defective in sexual development were generated by UV light and ethyl methanesulfonate mutagenesis (Masloff *et al.*, 1999, Pöggeler & Kück, 2004). Among them, three mutants pro11, pro22 and pro45 defective in STRIPAK function were detected (Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004). The STRIPAK complex is conserved in animals and fungi and fundamental developmental processes are governed by the STRIPAK complex. In yeasts its function is required for cytokinesis, septum formation, actin polymerization, autophagy and mitotic exit (Baryshnikova *et al.*, 2010, Gupta & McCollum, 2011, Pracheil & Liu, 2013, Singh *et al.*, 2011). In mammals, STRIPAK complex is required for normal function of neuronal cells and neuronal development, cell to cell adhesion, cytoskeleton organization and vesicular transport (Bai *et al.*, 2011, Baillat *et al.*, 2001, Bartoli *et al.*, 1999, Breitman *et al.*, 2008, Castets *et al.*, 1996). STRIPAK dysfunction was connected to neuronal and cardiac disease and to cancer (Bartoli *et al.*, 1999, Chen & Hsueh, 2012, Grand *et al.*, 2004, Hwang & Pallas, 2014, Ishikawa *et al.*, 2012, Lin *et al.*, 2010, Meurs *et al.*, 2010).

## Introduction

The STRIPAK complex in filamentous fungi is required during development and for virulence but STRIPAK signaling in filamentous fungi is poorly investigated (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Fu *et al.*, 2011, Green *et al.*, 2016, Islam *et al.*, 2017, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004, Shim *et al.*, 2006, Simonin *et al.*, 2010, Wang *et al.*, 2010, Wang *et al.*, 2016, Zhang *et al.*, 2017).

In this study, pull-downs of the central SmSTRIPAK component PRO11 (striatin) and its strong interaction partner SmMOB3 coupled to LC/MS were used to search for possible interacting partners. The aim was to identify and functionally analyze potential interaction partners of PRO11 and SmMOB3 in *S. macrospora*. An unstudied potential interaction partner, named SCI1 was identified with very high confidence. It's conservation among yeasts, filamentous fungi, the fruit fly and mammals should be investigated by phylogenetic analysis. As the SmSTRIPAK is involved in development, qRT-PCR should be performed to assess the regulation of the unstudied gene during sexual development. A *sci1* deletion mutant should be generated to investigate the role of the unstudied gene in vegetative growth, hyphal fusion and sexual development. To investigate direct interaction of the SCI1 protein with other known SmSTRIPAK components Y2H analysis should be performed. Also, pull-downs coupled to LC/MS with C-terminally eGFP-tagged SCI1 should assess, which proteins and STRIPAK proteins can be enriched. Mammalian and yeast orthologs of the identified protein should be transformed into the newly generated deletion mutant to investigate a possibly conserved function among phyla. Fluorescence microscopy studies will visualize the localization of the eGFP-tagged PRO11 and eGFP or DsRED-tagged SCI1. The STRIPAK in fungi, was connected to ER, mitochondria function, actin polymerization and vesicular traffic (Baryshnikova *et al.*, 2010, Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2010, Frey *et al.*, 2015a, Nordzieke *et al.*, 2015, Pracheil *et al.*, 2012). Therefore, morphology of nuclei, mitochondria and ER investigated by fluorescence microscopy as well as actin polymerization and endosome transport will help to shed light on the cellular function of SCI1.

## 2. Materials and Methods

$\Delta$ Smmob3_gpd- MOB3:DsRED	ectopic integration of pMob3DsRed into $\Delta$ SmMOB3; <i>nat</i> <sup>R</sup> , <i>hyg</i> <sup>R</sup> , pT, fertile, <i>Pgpd::Smmob3::Dsred::TtrpC</i>	Bernhards (2010)
wt::Dsred	ectopic integration of pRHN1 into S48977; <i>hyg</i> <sup>R</sup> , <i>ssi</i> , fertile, <i>Pgpd::Dsred::TtrpC</i>	Werner (2017)

## Materials and Methods

The native promoter and terminator of *sci1* are named 5'*sci1* and 3'*sci1* respectively. Other promoters and terminators are marked with a P or T respectively; ssi: single spore isolate, pT: primary transformant <sup>a</sup> Department for General and Molecular Botany, Ruhr-University Bochum

### 1.5.2 Plasmids

**Table 3: List of plasmids used and generated in this study**

Plasmid	Characteristics	Source
<b>Plasmid Backbones</b>		
pRS426	<i>amp<sup>R</sup></i> , <i>URA3</i>	Christianson and Fierke (1996)
pRSnat	<i>amp<sup>R</sup></i> , <i>URA3</i> , <i>nat</i>	Klix <i>et al.</i> (2010)
pRShyg	<i>amp<sup>R</sup></i> , <i>URA3</i> , <i>hph</i>	Bloemendal <i>et al.</i> (2012)
pFLAGN1	<i>amp<sup>R</sup></i> , <i>his-3</i> , <i>Pccg-1::flag</i>	Kawabata and Inoue (2007)
pHAN1	<i>amp<sup>R</sup></i> , <i>his-3</i> , <i>Pccg-1::ha</i>	Kawabata and Inoue (2007)
pCB1003	<i>amp<sup>R</sup></i> , <i>hph</i>	Carroll <i>et al.</i> (1994)
<b>Deletion constructs</b>		
pKOsci1hyg	<i>amp<sup>R</sup></i> , <i>URA3</i> , 899 bp of the 5'flanking region and 637 bp of the 3'flanking region of <i>sci1</i> interrupted by <i>hph</i> in pRS426	This study
pKOsci1nat	<i>amp<sup>R</sup></i> , <i>URA3</i> , 899 bp of the 5'flanking region and 637 bp of the 3'flanking region of <i>sci1</i> interrupted by <i>nat</i> in pRS426	This study
<b>Yeast two-hybrid plasmids</b>		
pGADT7	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>PADH1::GAL4AD::TADH1</i>	Takara Bio USA, Inc. (Mountain View, USA)
pA_rud3	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>sci1</i> amplified from cDNA <i>PADH1::GAL4AD::sci1::TADH1</i>	Nordzieke and Kück (unpublished)
pAD-pro11	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>pro11</i> amplified from cDNA <i>PADH1::GAL4AD::pro11::TADH1</i>	Bloemendal <i>et al.</i> (2012)
pAD-pro11(111-281)	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>pro11</i> (AA 111-281) amplified from cDNA <i>PADH1::GAL4AD::pro11<sub>111-281</sub>::TADH1</i>	Bloemendal <i>et al.</i> (2012)
pADpro45ΔTM	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>pro45</i> amplified from cDNA, without TM encoding sequence <i>PADH1::GAL4AD::pro45ΔTM::TADH1</i>	Teichert and Kück (unpublished)
pADRanBPM	<i>LEU2</i> , <i>GAL4-AD</i> , <i>amp<sup>R</sup></i> , <i>PADH1::GAL4AD::RanBPM::TADH1</i>	Tucker <i>et al.</i> (2009)

## Materials and Methods

pADFar3	<i>LEU2, GAL4-AD, amp<sup>R</sup>, FAR3</i> amplified from gDNA <i>PADH1::GAL4AD::FAR3::TADH1</i>	This study
pADFar7	<i>LEU2, GAL4-AD, amp<sup>R</sup>, FAR7</i> amplified from gDNA <i>PADH1::GAL4AD::FAR7::TADH1</i>	This study
pADFar8	<i>LEU2, GAL4-AD, amp<sup>R</sup>, FAR8</i> amplified from gDNA <i>PADH1::GAL4AD::FAR8::TADH1</i>	This study
pGBKT7	<i>TRP1, GAL4-BD, kan<sup>R</sup>,</i> <i>PADH1::GAL4BD::TADH1</i>	Takara Bio USA, Inc. (Mountain View, USA)
pB_rud3	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> amplified from cDNA <i>PADH1::GAL4BD::sci1::TADH1</i>	Nordzieke and Kück (unpublished)
pBDsci1 <sub>1-62</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 1-62) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>1-62</sub>::TADH1</i>	This study
pBDsci1 <sub>1-120</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 1-120) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>1-120</sub>::TADH1</i>	This study
pBDsci1 <sub>100-155</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 100-155) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>100-155</sub>::TADH1</i>	This study
pBDsci1 <sub>63-207</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 63-207) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>63-207</sub>::TADH1</i>	This study
pBDsci1 <sub>121-207</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 121-207) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>121-207</sub>::TADH1</i>	This study
pBDsci1 <sub>121-298</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 121-298) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>121-298</sub>::TADH1</i>	This study
pBDsci1 <sub>208-298</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, sci1</i> (AA 208-298) amplified from cDNA <i>PADH1::GAL4BD::sci1<sub>208-298</sub>::TADH1</i>	This study
pBDpro11 <sub>1-110</sub>	<i>TRP1, GAL4-BD, kan<sup>R</sup>, pro11</i> (AA 1-110) amplified from cDNA <i>PADH1::GAL4BD::pro11<sub>1-110</sub>::TADH1</i>	This study
pBD-pro11(1-110)	<i>amp<sup>R</sup>, URA2, pro11</i> cDNA fragment coding for fusion protein <i>BD-PRO11(1-110)</i> in <i>Sall</i> site in <i>pGBDU-C3</i>	Bloemendal <i>et al.</i> (2012)
pBDPRO45-FL	<i>TRP1, GAL4-BD, kan<sup>R</sup>, pro45</i> amplified from cDNA <i>PADH1::GAL4BD::pro45::TADH1</i>	Teichert and Kück (unpublished)
pBDpro45ΔTM	<i>TRP1, GAL4-BD, kan<sup>R</sup>, pro45</i> amplified from cDNA, without TM encoding sequence <i>PADH1::GAL4BD::pro45ΔTM::TADH1</i>	Teichert and Kück (unpublished)

### Expression plasmids

p1783-1	<i>amp<sup>R</sup>, URA3, hyg<sup>R</sup>,</i> <i>Pgpd::egfp::TtrpC</i>	Pöggeler <i>et al.</i> (2003)
pRHN1	<i>amp<sup>R</sup>, URA3, nat<sup>R</sup>,</i> <i>Pgpd::Dsred::TtrpC</i>	Janus <i>et al.</i> (2007)
pHA11	<i>amp<sup>R</sup>, URA3, nat<sup>R</sup>,</i> <i>Pccg1::ha::pro11::TtrpC</i>	Bloemendal <i>et al.</i> (2012)
pHAPRO11GFP	<i>amp<sup>R</sup>, URA3, nat<sup>R</sup>,</i> <i>Pccg1::ha::pro11::egfp::TtrpC</i>	Herzog and Pöggeler (unpublished)

pFar7FLAG	<i>amp<sup>R</sup>, URA3, nat<sup>R</sup>, Pccg1::FAR7::flag::TtrpC</i>	This study

### Others

pRRLsinhCMV-IG-FGFR1OP2_RN	Deletion in the 3'SIN-LTR promoter, WPRE posttranscriptional regulatory element, internal ribosome entry site fused to GFP IRES-GFP, wt <i>Rattus</i>	Lin <i>et al.</i> (2010)
----------------------------	---	--------------------------

## Materials and Methods

*norvegicus FGFR1OP2*, *hCMV* promoter, central polypurine tract/central termination sequence *cPPT/CTS*, chimeric 5' LTR 5'*ChimLTR*

pRRLsinhCMV-IG-FGFR1OP2_HS	Deletion in the 3' <i>SIN-LTR</i> promoter, <i>WPRE</i> posttranscriptional regulatory element, internal ribosome entry site fused to <i>GFP IRES-GFP</i> , wt <i>Homo sapiens FGFR1OP2/wit3.0β</i> , <i>hCMV</i> promoter, central polypurine tract/central termination sequence <i>cPPT/CTS</i> , chimeric 5' LTR 5' <i>ChimLTR</i>	Lin et al. (2010)
pRRLsinhCMV-IG-FGFR1OP2-SNP1_HS	Deletion in the 3' <i>SIN-LTR</i> promoter, <i>WPRE</i> posttranscriptional regulatory element, internal ribosome entry site fused to <i>GFP IRES-GFP</i> , wt <i>Homo sapiens FGFR1OP2/wit3.0β-SNP1</i> , <i>hCMV</i> promoter, central polypurine tract/central termination sequence <i>cPPT/CTS</i> , chimeric 5' LTR 5' <i>ChimLTR</i>	Lin et al. (2010)

The native promoter and terminator of *sci1* are named 5'*sci1* and 3'*sci1*, respectively. Other promoters and terminators are marked with a *P* or *T*, respectively; *Pgpd*: promoter of the glycerin aldehyde 3-phosphate dehydrogenase (*Aspergillus nidulans*), *TrpC*: Promoter of the *trpC* gene of the anthranilate synthase pathway (*A. nidulans*); *Pccg1*: promoter of the *clock controlled gene 1* of *N. crassa*; *amp<sup>R</sup>*, ampicillin resistance; *kan<sup>R</sup>*, kanamycin resistance; *hyg<sup>R</sup>*, resistance to hygromycin, hygromycin B phosphotransferase; *nat<sup>R</sup>*: resistance to nourseothricin, nourseothricin N-acetyl transferase, The amino-acid (AA) region encoded by the fragment shown is given in brackets or is written in lower case.

### 1.5.3 Primers

**Table 4: List of primers used in this study**

Overhangs for homologous recombination in yeast are underlined. The region of overhangs homologous to the respective plasmid or gene is given and also underlined. Additional bp for generation of a stop codon (if required) are shaded in gray.

### 1.5.4 Chemicals and materials

#### 1.5.4.1 Chemicals

Acetic acid (Roth GmbH, 3738.2), acetonitrile (Roth GmbH, 8825), acrylamide (Rotiphorese® Gel 40 37,5:1) (Roth GmbH, 3029.1), adenine (Sigma-Aldrich, 01830-50G), agar-agar (Roth GmbH, 5210.2), agar-agar SERVA high gel-strength (SERVA, 11396.03), agarose (Biozym Scientific GmbH, 840004), albumin bovine (Sigma-Aldrich, A9647-50G), ammonium bicarbonate (Sigma-Aldrich, A6141), ammonium chloride (VWR International, BDH0208-500G), ammonium sulfate (AppliChem, A1032.1000), ammonium persulfate (APS) (Roth GmbH, 9592.3), ampicillin (Sigma-Aldrich, A9518-25G), bacto-yeast-extract (Oxoid LTD., LP0021),  $\beta$ -mercaptoethanol (Roth GmbH, 4227.1), bio malt maize extract (Brau-Partner Kling, 115), biotin (Sigma-Aldrich, B4501-1G), boric acid (Roth GmbH, 6943.1), bromophenol blue (AppliChem, A3640.0005), calcium chloride (Roth GmbH, CN92.1), calcium chloride (Roth GmbH, CN92.1), calcium chloride dihydrate (Roth GmbH, 5239.1), CFW (calcoflour white stain) (Sigma-Aldrich, 18909-100ML-F), citric acid monohydrate (Roth GmbH, 3958.1), CMAC (7-amino-4-chloromethyl-coumarin) (Invitrogen, C-2110), copper (II) sulfate 5-hydrate (Roth GmbH, P024.1), Coomassie® brilliant blue R-250 (Serva, 17525), CSM-Ade-His-Leu-Trp-Ura (MP Biomedicals, 4550-122), DAPI (4'-6-diamidino-2-phenylindole) (AppliChem, A1001.0010), deoxynucleotide triphosphates (dNTPs) (Thermo Scientific, R0191), deoxyribonucleic acid sodium salt from salmon testis (ss-DNA) (Sigma Aldrich, D1626-1G), disodium hydrogen phosphate (Merck-Millipore, 1065855000), DMF (dimethylformamide) (Roth GmbH, T921.1) DMSO (dimethyl sulfoxide) (Merck Millipore, 1029310500), DTT (1,4-dithiothreitol) (AppliChem, A1101.0025), EDTA (ethylenediamine tetraacetic acid disodium salt dihydrate) (Roth GmbH, 8043.2), EDTA-free protease inhibitor cocktail (Roche, 04693132001), ethanol (VWR International, 20821.321), ethidium bromide (EtBr) (Sigma-Aldrich, 46065), FM 4-64 (Invitrogen, F34653), formaldehyde (Roth GmbH, 4979.2), formic acid (Merck Millipore, 1002641000), GeneRuler™ DNA Ladder Mix (Thermo Scientific, SM0331), GeneRuler™ 1kb DNA Ladder (Thermo Scientific, SM0313), glucose (AppliChem, A3617.1000), glycerol (VWR International, 24388.295), glycine (Roth GmbH, 0079.1), glycerin ROTIPURAN® (Roth GmbH, 200-289-5), HEPES (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid) (Roth GmbH, 9105.4), hydrochloric acid (Roth GmbH, 4625.2), hydrogen peroxide 30% (H<sub>2</sub>O<sub>2</sub>) (Merck Millipore, 8.22287.2500), hygromycin B (Merck-Millipore, 400051-10MU), iodoacetamide (Sigma-Aldrich, I1149), iron (II) chloride (Roth GmbH, 231-753-5), iron(II) sulfate heptahydrate (Sigma-Aldrich, 31236), imidazole (Roth GmbH, X998.1), isopropanol (AppliChem, A0900,2500GL), kanamycin sulfate (Sigma-Aldrich, 60615), L-arginine (Roth, 3144.1), L-histidine (AppliChem, A3738.0100), L-leucine (AppliChem, A1426.0100), lithium acetate (Roth GmbH, 5447.1), magnesium chloride hexahydrate (Merck Millipore, 1.05833.1000), L-tryptophan (MP Biomedicals, 4061-012), magnesium sulfate heptahydrate (Roth GmbH, P027.2), maize flour (Mühle Levers, Bochum, Germany and Mühle Udo Kellner, Schimberg, Germany), manganese (II) chloride tetrahydrate (Roth GmbH, T881.1), manganese (II) sulfate monohydrate (Roth GmbH, 4487.1), Maxima SYBR Green/ROX qPCR master mix (2x) (Thermo Fisher, K0221), methanol (VWR International, 20864.320), Nonidet® (NP40) (AppliChem A2239.0025), nourseothricin

## Materials and Methods

(WernerBioAgents, 5004000), NuPAGE™ LDS Sample Buffer (4x) (Thermo Scientific Invitrogen, NP0007), PageRuler™ prestained protein ladder (Thermo Scientific, 26616), PEG 4000 (Polyethylene Glycol 4000) (AppliChem, A1249.1000), PEG 6000 (Polyethylene Glycol 6000) (Sigma-Aldrich, 81255), phenol (AppliChem, A1153.0500), phosphoric acid (Roth GmbH, 6366.1), 5x phusion HF buffer (Thermo Scientific, F518), PMFS (phenylmethylsulfonyl fluoride) (Serva, 32395), potassium acetate (Merck Millipore, 1.04820.1000), potassium chloride (AppliChem, A3582,1000), potassium dihydrogen phosphate (Merck Millipore, 1.04873.1000), potassium hydroxide (Roth GmbH, 6751.1), potassium nitrate (Merck Millipore, 1.05063.1000), potassium nitrite (Sigma-Aldrich, 31443), RNA gel loading dye (2x) (Thermo Scientific, R0641), Rotiphorese Gel 30 (Roth GmbH, 3029.1), saccharose (Roth GmbH, 200-334-9), Roti®-Quant (5x) (Roth, K015.1), SDS (sodium dodecyl sulfate) (Roth GmbH, 4360.2), Difco™ skim milk (BD Biosciences, 232100), sodium acetate (Roth GmbH, 6773.2), sodium chloride (AppliChem, A3597,1000), sodium dihydrogen phosphate monohydrate (Merck Millipore, 1.06346.1000), sodium hydroxide (VWR International, 28244.295), Difco™ soluble starch (BD Biosciences, 217820), sorbitol (Roth GmbH, 6213.1), sucrose (AppliChem, A4734.1000), TEMED (N,N,N',N'- tetramethylethylenediamine) (Roth GmbH, 2367.1), TRIS PUFFERAN® (Tris-hydroxymethyl-aminomethane) (Roth GmbH, AE15.2), TRIS hydrochlorid (Roth GmbH, 9090.3), Trizol (Invitrogen,15596026), trypsin resuspension dilution buffer (Promega, V542A), tryptone/peptone (Roth GmbH, 8952.2), Tween 20® (AppliChem, A4974.0100), uracil (Sigma-Aldrich, U1128), urea (Roth GmbH, 2317.3), Water for chromatography (Merck Millipore, 7732-18-5), xylene cyanol (AppliChem, A4976.0005), yeast extract (Thermo Scientific, LP0021), Difco™ yeast nitrogen base w/o amino acids and ammonium sulfate (BD Biosciences, 233520), zinc chloride (Sigma-Aldrich, 14424), zinc sulfate heptahydrate (Roth GmbH, K301.1)

### 1.5.4.2 Materials

Amersham Hybond™ -N<sup>+</sup> (GE Healthcare, RPN203B), Amersham Hyperfilm™ ECL (GE Healthcare, 28906837), Amersham™ Protran™ Nitrocellulose Blotting Membrane 0.45µm (GE Healthcare, 10600003), anti-HA-agarose beads (Merck, A2095), BioDocAnalyzer (Biometra, Germany), disposable cuvettes 10x4x45 (Sarstedt, 67.742), Electroporation cuvettes (VWR International, 732-1137), Empore™ Solid Phase Extraction Disk C18/47mm (Neuss, 2215, 3M), Flat Optical 8-Cap Strip 0.2 ml (Biozym, 712100), Frit (ROBU glass, pore size1), GFP-Trap\_A (Chromotek, gta-20), glass beads Ø 0.25-0.5 mm (Roth GmbH, A553.1), glass beads Ø 2.85-3.45 mm (Roth GmbH, A557.1), 0.2 ml Low Profile 8er-Strips (Biozym, 621935), Protein LoBind Tubes (Eppendorf, 0030108116), Sepharose A (GE Healthcare, 17078001), sterile filter 0.45/0.2 µm (Sarstedt, 83.1826/83.1826.001), Whatman Paper B002 580x600 mm (Schleicher & Schuell, 88-3852)

### 1.5.5 Kits

AlkPhos Direct Labelling and Detection Kit (Amerham, GE Healthcare, RPN3680), CloneJET PCR Cloning Kit (Thermo Scientific, K1231), FastGene® Plasmid Mini Kit (Nippon Genetics Co., Ltd, FG-90402), Immobilon™ Western HRP Substrate (Merck Millipore, WBKL S0100), QIAprep Spin Miniprep Kit (Qiagen, 27106), QIAquick Gel Extraction Kit (Qiagen, 28704), QIAquick PCR

## Materials and Methods

Purification Kit (Qiagen, 28104), QuantiTect Rev. Transcription Kit (Qiagen, 205311), Rapid DNA Dephos & Ligation Kit (Roche, 04898117001), Transcriptor High Fidelity cDNA Synthesis Kit (Roche, 05091284001), ZR Fungal/Bacterial DNA MiniPrep™ (Zymo Research, D6005)

### 1.5.6 Enzymes

DNase I (Thermo Scientific, EN0521), HotstarTaq Master Mix (Qiagen, 203443), In-fusion HD enzyme premix 5x (Clontech 639648), Lysozyme (Serva, 28262.03), Natuzym (Schliessmann, 5090), Pfu polymerase (Promega GmbH, M7741), Phusion High-Fidelity DNA polymerase (Thermo Scientific, F-530L), restriction endonucleases (Thermo Scientific), RNase A (AppliChem, A2760,0100), T4 DNA ligase (Thermo Scientific, EL0011), TopTaq DNA Polymerase (Qiagen, 200203), Trypsin NB sequencing grade modified from porcine pancreas (Serva, 37283.01)

### 1.5.7 Antibodies

The primary antibodies listed in table 5 were used for detection of fusion proteins. If required a secondary antibody was applied. For detection, the secondary antibody or the anti-GFPHRP antibody were used, which are coupled to horseradish peroxidase catalyzing oxidation of luminol and emitting light.

**Table 5: Antibodies used for detection of eGFP, DsRED, HA or FLAG-tagged fusion proteins**

Antibody	Supplier, Order Number	Host	Dilution range	Clonality
<b>Primary antibody</b>				
anti-FLAG M2	Sigma-Aldrich, F3165,	Mouse	1:12000	Monoclonal
anti-HA, clone-HA7	Sigma-Aldrich, H9658	Mouse	1:3000	Monoclonal
anti-RFP	GenScript, A00682	Rabbit	1:2000	Polyclonal
anti-GFPHRP	Acris Antibodies, R1091HRP	Goat	1:3000	Polyclonal
<b>Secondary antibody</b>				
anti-Mouse	Dianova/Jackson ImmunoResearch, 115-035-003	Goat	1:10000	Polyclonal
anti-Rabbit	Life Technologies, G21234	Goat	1:2000	Polyclonal

### 1.5.8 Buffers and solutions

#### Medium supplements

##### *E.coli*

Ampicillin stock solution: 100 mg/mL in H<sub>2</sub>O  
Kanamycin stock solution: 30 mg/mL in H<sub>2</sub>O

## Materials and Methods

### ***S. cerevisiae***

Adenine stock solution:	0.02% (w/v) adenine in H <sub>2</sub> O <sub>dest</sub>
Histidine stock solution:	1% (w/v) histidine in H <sub>2</sub> O <sub>dest</sub>
Leucine stock solution:	1% (w/v) leucine in H <sub>2</sub> O <sub>dest</sub>
Tryptophan stock solution:	0.02% (w/v) tryptophan in H <sub>2</sub> O <sub>dest</sub>
Uracil stock solution:	0.02% (w/v) uracil in H <sub>2</sub> O <sub>dest</sub>

### ***S. macrospora***

Hygromycin B stock solution:	~440 MU/mL
Nourseothricin stock solution:	200 mg/mL
SWG trace elements solution:	5% (w/v) citric acid, 5% (w/v) ZnSO <sub>4</sub> x 7 H <sub>2</sub> O, 1% (w/v), Fe(NH <sub>4</sub> ) <sub>2</sub> (SO <sub>4</sub> ) <sub>2</sub> x 6 H <sub>2</sub> O, 0.25 % (w/v) CuSO <sub>4</sub> x 5 H <sub>2</sub> O, 0.05% (w/v) MnSO <sub>4</sub> x H <sub>2</sub> O, 0.05% (w/v) H <sub>3</sub> BO <sub>3</sub> , 0.05% (w/v) Na <sub>2</sub> MoO <sub>4</sub> x 2 H <sub>2</sub> O, 1% (v/v) chloroform
Arginine stock solution:	100 mg/mL in H <sub>2</sub> O <sub>dest</sub>
Biotin stock solution:	0.01% (w/v) biotin, 50% (v/v) ethanol
	Westergaard solution (1x): 0.1% (w/v) KNO <sub>3</sub> , 0.1% (w/v) KH <sub>2</sub> PO <sub>4</sub> , 0.05% (w/v) MgSO <sub>4</sub> heptahydrate, 0.01% (w/v) NaCl, 0.01% (w/v) CaCl <sub>2</sub> , 0.01% (v/v) 0.01 % SWG trace-elements solution
CMS trace elements solution:	10 mg/L ZnSO <sub>4</sub> , 10 mg/L Fe(II)Cl <sub>2</sub> , 10 mg/L MnCl <sub>2</sub>

### **PCR and gel electrophoresis:**

#### ***DNA***

dNTP-Mix (10 mM):	of each nucleotide dATP, dCTP, dGTP, dTTP, 10 mM in H <sub>2</sub> O
DNA loading dye (6x):	0.25% (w/v) xylene cyanol FF, 0.25% (w/v) bromophenol blue, 40% (w/v) sucrose
TBE (10 x):	1 M Tris adjusted with HCl, 1 M boric acid, 20 mM EDTA, pH 8.3
Agarose gel:	1% or 2% (w/v) agarose in 1 x TBE
EtBr stock solution:	10 mg/mL EtBr in H <sub>2</sub> O

#### ***RNA***

MOPS buffer (10 x):	0.2 M MOPS (pH 7.0), 50 mM sodium acetate, 10 mM EDTA (pH 8.0)
Agarose gel with MOPS:	1.25% (w/v) agarose in 1 x MOPS/0.8% (v/v) formaldehyde (37%)

### **Purification of nucleic acids**

BD solution I:	50 mM glucose, 10 mM EDTA, 25 mM Tris adjusted with HCl to pH 8.0; Add 0.4 g lysozyme per 200 µL BD I for working solution
BD solution II:	400 mM NaOH and 2% SDS freshly mixed 1:1
BD solution III:	3 M potassium acetate, 5.4% (v/v) formic acid

## Materials and Methods

Lysis buffer: 10 mM Tris adjusted with HCl, pH 8.0, 1 mM EDTA, 100 mM NaCl, 2% (w/v) SDS (freshly prepared working solution)  
(*S. macrospora* gDNA)

### **Southern blotting**

Prehybridization buffer: 0.5 M NaCl solved in 4% “blocking reagent”  
Southern blot buffer I: 0.25 M HCl  
Southern blot buffer II: 0.5 M NaOH, 1.5 M NaCl  
Southern blot buffer III: 1.5 M NaCl/0.5 M Tris base  
First wash buffer: 2 M Urea, 150 mM NaCl, 1 mM MgCl<sub>2</sub>, 50 mM NaH<sub>2</sub>PO<sub>4</sub> x H<sub>2</sub>O (pH 7.0), 50 mM SDS and 0.2% blocking agent  
Second wash buffer (20 x): 1 M Tris base, 2 M NaCl, pH 10.0

### **Transformation of organisms**

#### ***E. coli***

TB: 10 mM HEPES, 15 mM CaCl<sub>2</sub> x H<sub>2</sub>O, 250 mM KCl, 55 mM MnCl<sub>2</sub> x H<sub>2</sub>O, pH 6.7

#### ***S. cerevisiae***

TE (10x): 100 mM Tris pH 8.0, 10 mM EDTA  
TE(D)(10x): 100 mM Tris adjusted with HCl, 10 mM EDTA, pH 7.2  
Lithium acetate (10x): 1 M lithium acetate, pH 7.5  
LiAcTE(D) (1x): TE(D)(10x) and lithium acetate (10x) mixed 1:1 adjusted to the final volume with H<sub>2</sub>O<sub>dest</sub>  
LiAcTE(D)/PEG: 50% (w/v) PEG 4000, TE(D)(10x) and lithium acetate (10x) mixed 1:1 adjusted with H<sub>2</sub>O<sub>dest</sub> to the final volume  
Salmon sperm (ss) DNA: 10 mg/mL ssDNA in 1 x TE  
DTT solution: 1 M DTT in H<sub>2</sub>O  
Sorbitol: 1 M sorbitol in H<sub>2</sub>O

#### ***S. macrospora***

Protoplast buffer (PPB): 13 mM Na<sub>2</sub>HPO<sub>4</sub>, 45 mM KH<sub>2</sub>PO<sub>4</sub>, 600 mM KCl, pH 6.0  
Transformation buffer (TPS): 1 M sorbitol, 80 mM CaCl<sub>2</sub>, pH 7.4

### **Western blot/Protein methods**

#### ***Protein isolation***

GFP-Trap lysis buffer: 10 mM Tris, pH 7.5, 150 mM NaCl; 10% glycerol, 0.5 mM EDTA and freshly added 0.5% Nonidet<sup>®</sup> P40, 2 mM DTT, 1 mM PMSF, 1 x EDTA-free protease inhibitor cocktail (Roche)  
GFP-Trap dilution buffer: 10 mM Tris, pH 7.5, 150 mM NaCl, 0.5 mM EDTA

## Materials and Methods

### ***SDS-PAGE and blotting***

Protein loading dye (5x):	125 mM Tris, pH 6.8, 5% (v/v) $\beta$ -mercaptoethanol, 50% (v/v) glycerol 0.01% (w/v), bromphenol blue, 2 % (w/v) SDS
SDS-running buffer (10 x):	250 mM Tris and 2 M glycine adjusted with HCl to pH 8.3, 1% (v/v) SDS
Transfer buffer:	25 mM Tris, 200 mM glycine, 20% (v/v) methanol
TBS (10 x):	100 mM Tris adjusted with HCl to pH 7.5, 1.5 M NaCl
TBST (1x)	TBS 1x freshly added 0.05% (v/v) Tween 20 <sup>®</sup>
Blocking reagent:	Difco <sup>™</sup> skim milk 5% (w/v) in 1x TBST
Immunolabelling solution:	1x TBST with 5% (w/v) skim milk and antibody as described by the manufacturer

### ***Coomassie<sup>®</sup> brilliant blue staining/destaining***

Decolouriser I:	10% (v/v) acetic acid, 40% (v/v) ethanol
Coomassie stain Stock I:	0.2% (w/v) Coomassie <sup>®</sup> brilliant blue R-250 in 90% (v/v) ethanol
Coomassie stain Stock II:	20% (v/v) acetic acid
Staining solution:	Coomassie stain stock I and stock II mixed freshly 1:1
Decolouriser II:	10 % (v/v) acetic acid, 20% (v/v) ethanol

### ***Trypsin digest/sample preparation for LC/MS***

LC/MS sample buffer:	freshly made, 2% (v/v) acetonitrile, 0.1% (v/v) formic acid
----------------------	---

## 1.5.9 Media

### ***E. coli***

#### **Lysogeny broth (LB):**

1% (w/v) tryptone, 0.5% (w/v) yeast extract, 0.5% (w/v) NaCl, pH 7.2. Add 1.5% (w/v) agar-agar for solid medium; add ampicillin (100  $\mu$ g/mL) or kanamycin (30  $\mu$ g/mL) for selection of transformants.

#### **Super optimal both (SOB):**

2% (w/v) tryptone, 0.5% (w/v) yeast extract, 10 mM NaCl, 2.5 mM KCl, 10 mM MgCl<sub>2</sub>, 10 mM MgSO<sub>4</sub>, pH 7.0

### ***S. cerevisiae***

#### **Yeast extract peptone dextrose (YEPD):**

2% (w/v) tryptone, 1% (w/v) yeast extract, 2% (w/v) glucose, pH 5.8. Add 1.5% (w/v) SERVA agar-agar for solid medium.

### **Synthetic defined (SD):**

0.17% (w/v) Difco™ Yeast Nitrogen Base w/o amino acids and ammonium sulfate, 2% (w/v) glucose, 0.064% (w/v) CSM-Ade-His-Leu-Trp-Ura (0.002% (w/v) L-methionine, 0.005% (w/v) L-arginine hydrochloride, 0.005% (w/v) L-isoleucine, 0.005% (w/v) L-lysine hydrochloride, 0.005% (w/v) L-phenylalanine, 0.005% (w/v) L-tryptophan, 0.005% (w/v) L-tyrosine, 0.008% (w/v) L-aspartic acid, 0.01% (w/v) L-leucine and L-threonine, 0.014% (w/v) L-valine), pH 5.8; 1.5% (w/v) SERVA agar-agar for solid medium. For selection or Y2H drop experiments prepare SD medium lacking respective amino acid(s).

### **S. macrospora**

#### **Biomalt maize medium (BMM):**

0.8% (w/v) corn flour (25 g/L), pH 6.5; 8 g/L malt extract; add 1.5% (w/v) agar-agar for solid medium; selection of transformants with Nourseothricin (50 µg/mL) or Hygromycin B (110 U/mL); For sporulation induction add 0.5% (w/v) sodium acetate.

#### **Complex rich medium with 10.8% sucrose (CMS):**

1% (w/v) glucose, 0.2% (w/v) tryptone, 0.2% (w/v) yeast extract, 10.8% (w/v) sucrose, 0.15% (w/v) KH<sub>2</sub>PO<sub>4</sub>, 0.05% (w/v) KCl, 0.05% (w/v) MgSO<sub>4</sub> heptahydrate, 0.37% (w/v) NH<sub>4</sub>Cl, trace elements (10 mg/L ZnSO<sub>4</sub>, 10 mg/L Fe(II)Cl<sub>2</sub>, 10 mg/L MnCl<sub>2</sub>), pH 6.5; Add 2% (w/v) agar-agar for solid medium.

#### **Sordaria Westergaards medium (SWG):**

1x Westergaard solution, 2% (w/v) glucose, 0.1% (w/v) arginine, 0.1% (v/v) biotin, pH 6.5; Add 1.5% (w/v) agar-agar for solid medium.

#### **Minimal medium starch (MMS):**

0.1% (w/v) soluble starch, 1.8 mM KH<sub>2</sub>PO<sub>4</sub>, 1.7 mM K<sub>2</sub>HPO<sub>4</sub> x 3H<sub>2</sub>O, 8.3 mM urea, 1 mM MgSO<sub>4</sub> x 7H<sub>2</sub>O, 100 µL trace elements solution 2, 0.006 mg/mL biotin, pH 6.5; Add 2% (w/v) agar-agar for solid medium.

#### **Prep agar:**

5% Agar-agar in H<sub>2</sub>O

#### **Top-agar:**

0.8 M NaCl, 0.8% (w/v) agar-agar, 250 µg/mL Nourseothricin, 550 U/mL Hygromycin B.

## **1.6 Methods**

### **1.6.1 Cultivation of microorganisms**

#### **E. coli**

*E. coli* strains were grown in liquid LB and 200 rpm or on solid LB medium at 37°C over night (Sambrook & Russell, 2001). The selection was performed on LB plates supplemented with ampicillin (100 µg/mL) or kanamycin (30 µg/mL). *E. coli* strains for preparation of competent cells were grown in liquid SOB medium at 20 °C and 50 rpm overnight.

### **S. cerevisiae**

*S. cerevisiae* PJ69-4A was grown at 30 °C on solid or in liquid YEPD or SD medium at 120 rpm overnight. Transformants were selected on solid SD medium supplemented with appropriate amino acids.

### **S. macrospora**

*S. macrospora* strains were grown at 27°C on liquid or solid CMS, BMM, SWG or MMS with continuous light (Elleuche & Pöggeler, 2008, Esser, 1982, Nowrousian *et al.*, 1999, Rech *et al.*, 2007). The vegetative growth velocity was documented in 30 cm race tubes filled with 25 mL solid SWG medium. Each race tube was inoculated with a mycelia plug of 0.5 cm in diameter (Nolting & Pöggeler, 2006). The distance covered by the growing mycelium was measured every 24 hours with a ruler over 7 days (Nowrousian & Cebula, 2005). The average vegetative growth velocity was calculated from 3 independent experiments, each performed in triplicates (n=3).

Analyses of *S. macrospora* strains under stress conditions were performed on SWG medium containing, 0.01% H<sub>2</sub>O<sub>2</sub>, 0.1 M NaCl, 0.01 M CaCl<sub>2</sub>, 0.4 M sorbitol, 0.003% SDS, 100µg/mL CFW or on SWG with 0.6 M glucose or without KNO<sub>3</sub>. A mycelia plug of 0.5 cm in diameter was placed on top of the stress inducing media and strains were grown for 7 days, at 27 °C under continuous light.

## **1.6.2 Preparation of competent microorganisms and transformation procedure**

### **E. coli**

*E. coli* cells were made competent for cloning and propagation of recombinant plasmids like described by Hanahan *et al.* (1991). *E. coli* cells were grown in liquid SOB medium to an optical density (OD<sub>600</sub>) of 0.6. Cells were incubated on ice for 10 min, centrifuged at 2500 g (4 °C), resuspended in 16 mL TB and centrifuged again for 10 min at 2500 g (4°C). The pellet was resuspended in 4 mL TB and 280 µL DMSO. After 10 min incubation, chemically competent cells were immediately frozen in 100 µL aliquots in liquid nitrogen and stored at - 80 °C. Chemically competent *E. coli* cells were thawed on ice and combined with plasmid DNA. After 20 min incubation on ice, cells were heat shocked for 1 min at 42 °C, placed for 2 min on ice and allowed to recover in 600 µL liquid LB at 37 °C for 45 min at 180 rpm (Sambrook & Russell, 2001). Selection was performed on LB supplemented with the appropriate antibiotic.

### **S. cerevisiae**

Homologous recombination was used to generate recombinant plasmids in *S. cerevisiae* strain PJ69-4A (James *et al.*, 1996, Colot *et al.*, 2006). Yeast cells were made electrocompetent as follows. A 50 mL *S. cerevisiae* cell culture grown in YEPD (OD<sub>600</sub> of 0.8-1.2) was pelleted at 3000 g for 5 min, resuspended in 1 x LiAc /TE(D) and incubated for 45 min at 30 °C and 100 rpm. DTT (0.5 mL of a 1 M DTT stock) was added, followed by further 10 min incubation at 30 °C at 100 rpm. Yeast cells were pelleted, washed once with water and once with 1 M sorbitol and stored in 1 M sorbitol (40

## Materials and Methods

μL aliquots) until transformation was performed. For the transformation 500 ng DNA was added to the cells in 0.2 cm electroporation cuvettes, followed by 10 min incubation on ice. Immediately after electroporation, using an Eppendorf Electroporator 2510 (Eppendorf, Hamburg, Germany) at 1.5 kV (Becker & Lundblad, 2001), 800 μL of 1 M sorbitol was added and yeast cells dependent on the plasmid backbone used were selected for uracil, leucine or tryptophan prototrophy.

For Yeast two-hybrid (Y2H) experiments AD and BD plasmids were cotransformed into chemical competent *S. cerevisiae* PJ69-4A (Gietz & Schiestl, 2007). The yeast cells (10 mL for 2 transformation samples) were grown to an OD<sub>600</sub> of 0.6-0.8, pelleted at 3000 g for 5 min, resuspended in 10 mL 1 x LiOAcTE(D) and shaken gently. Cells were pelleted again, the supernatant was removed and yeast cells were resuspended in a total volume of 400 μL LiOAcTE(D). For transformation 200 μL of yeast cells were combined with ssDNA (1 mg/mL), 200-800 ng Plasmid DNA and 800 μL 50% PEG4000 (w/v) in LiOAcTE(D). The samples were vortexed and incubated for 30 min at 30 °C and occasionally shaken gently. In the next step, yeast cells were incubated for 25 min at 42 °C and pelleted for 30 sec at 7000 g. The supernatant was removed and cells were resuspended in 1 mL YEPD medium. After recovery (1h at 30 °C) under continuous shaking, yeast cells were selected for leucine and tryptophan prototrophy.

### **Sordaria macrospora**

*S. macrospora* protoplasts were generated (Pöggeler *et al.*, 1997) and transformation with recombinant plasmids was performed as described previously (Engh *et al.*, 2007, Walz & Kück, 1995). *S. macrospora* mycelium was grown in liquid cultures for 3 days, harvested and transferred to PPB containing 20 mg/mL Natuzym. After 3 h incubation at 27°C and continuous shaking at 100 rpm protoplasts were harvested with the help of a frit. Protoplasts were washed twice once with 10 mL PPB and second with 5 mL PPB. Centrifugation was performed for 4 min at 4000 g at room temperature and protoplasts were resuspended in 100 μL TPS. Each transformation sample with a volume of 100 μL was combined with 20 μg plasmid DNA and incubated for 10 min on ice. Subsequently, 25% (w/v) PEG6000 in TPS was added and the samples were gently mixed. After 20 minutes incubation at room temperature the protoplast solution was spread on CMS plates and incubated at 27 °C for 24 hours. CMS plates with regenerated protoplasts were covered with 9 mL top-agar containing the appropriate antibiotic(s). Selection of transformants was performed on BMM media containing nourseothricin (50 μg/mL) and/or hygromycin B (110 U/mL).

### **1.6.3 Generation of *S. macrospora* deletion strains**

#### **1.6.3.1 Generation of *S. macrospora* single deletion strains**

The plasmids pKOsci1hyg or pKOsci1nat encoding the deletion cassettes for generation of the *S. macrospora* strains Δsci1<sub>hyg</sub> and Δsci1<sub>nat</sub> were constructed by homologous recombination (1.6.2) in *S. cerevisiae* (Colot *et al.*, 2006). The primer pair rud3\_5'f/rud3\_5'r amplified the 5' flanking region of *sci1* (899 bp). For amplification of the *sci1* 3' flank, the primer pair rud3\_3'f/rud3\_3'r (637 bp) (overhang to the *hph* resistance cassette) or the primer pair Sci1\_3'f\_nat/ rud3\_3'r, (637) bp

(overhang to the *nat* resistance cassette) were used. The flanking regions were amplified from *S. macrospora* genomic DNA and contained an overhang of 29 bp to the pRS426 vector (Christianson *et al.*, 1992) and to the *hph* or *nat* cassette. The resistance cassette containing the *trpC* promoter sequence of *A. nidulans* fused to the *hph* resistance or *nat* resistance gene was amplified with the primer pair *hph-f/hph-r* from the plasmid pCB1003 or with the primer pair *hph-f/nat-1r* from the plasmid pRSnat, respectively. The *hph* cassette had a size of 1385 bp and the *nat* cassette was 929 bp in size.

The fragments of the *sci1* flanking regions and the respective resistance cassettes were cotransformed with a *XhoI* linearized pRS426 vector into the *S. cerevisiae* strain PJ69-4A (James *et al.*, 1996) for homologous recombination (Mayrhofer *et al.*, 2006) (1.6.2). Selection was performed on SD-Ura medium. The recombinant plasmids pKOsci1hyg or pKOsci1nat were isolated from yeast and transformed into *E. coli* (1.6.2). Positive clones were selected on LB medium supplemented with ampicillin. Plasmids were isolated from *E. coli* (1.6.8.5) and verified by sequencing (1.6.8.10). The deletion cassettes were amplified from pKOsci1hyg or pKOsci1nat with the primer pair *rud3\_5'f/rud3\_3'r*. The *sci1* open-reading frame (ORF) in the nourseothricin resistant *S. macrospora* strain  $\Delta ku70$  (S66001) was replaced by the *hph* cassette (2.2.2). The *sci1* ORF in the hygromycin resistant *S. macrospora* strain  $\Delta ku80::hph$  (Herzog and Pöggeler, unpublished) was replaced by the *nat* cassette. To eliminate the  $\Delta ku70$  or the  $\Delta ku80$  background hygromycin/nourseothricin resistance strains were crossed against the *fus1-1* (S84595) (Nowrousian *et al.*, 2012) strain and single spore isolates (*ssi*) resistant to hygromycin ( $\Delta sci1_{hyg}$ ) or nourseothricin ( $\Delta sci1_{nat}$ ) were selected on BMM supplemented with sodium acetate (1.5.9). For the  $\Delta sci1_{hyg}$  strain also brown single spore isolates were selected and the strain was named *fus* $\Delta sci1_{hyg}$ . Strains with *sci1* deletion ( $\Delta sci1_{hyg}$  or  $\Delta sci1_{nat}$ ) were tested by PCR and by Southern blot (Southern, 1975) (1.6.8.1, 1.6.8.7, 1.6.8.8).

### 1.6.3.2 Generation of *S. macrospora* double deletion strains

The  $\Delta sci1$  strains and the  $\Delta pro11$  strain are hyphal fusion defective. To obtain a double deletion *fus* $\Delta sci1_{hyg}$  was transformed with a plasmid construct *p5'sci1gfp* (1.6.4.1) encoding the endogenous promoter of *sci1* and the *sci1* gene fused to *egfp-trpC*. Hygromycin and nourseothricin resistant strains were selected, which complemented the sterile  $\Delta sci1_{hyg}$  phenotype. The fertile *fus* $\Delta sci1_{hyg}::5'sci1egfp$  strain was crossed to the sterile  $\Delta pro11$  strain and hygromycin resistant and nourseothricin sensitive single spores were selected. The double deletion strain  $\Delta sci1_{hyg}\Delta pro11$  was verified by PCR (1.6.8.1).

#### 1.6.4 Generation of *sci1* expression plasmids for transformation into *S. macrospora*

Expression plasmids were generated to synthesize C-terminally eGFP- or DsRED full-length SCI1 proteins in *S. macrospora*. Also, constructs containing *sci1* fragments were generated to express fragments of *sci1* in the  $\Delta sci1_{hyg}$  strain.

##### 1.6.4.1 Generation of *sci1* full length constructs for transformation into *S. macrospora*

*Sci1-egfp* or *sci1-Dsred* fusion gene constructs under the control of the endogenous *sci1* promoter were generated. The 5' flanking region of *sci1* containing the endogenous promoter of *sci1* and the *sci1* ORF were amplified with the primer pair *rud3\_5'f/sci1gfp\_r* (1875 bp) from *S. macrospora* gDNA. The primers had 29 bp overhangs to the pRSnat plasmid and to the *egfp* sequence, respectively. The *egfp* sequence fused to the *trpC* terminator sequence of *A. nidulans* was amplified from the plasmid p1783-1 with the primer pair GFP-f/pRS426GFPprev (1510 bp) generating a 29 bp overhang to pRSnat. Homologous recombination of both fragments with *XhoI* hydrolyzed pRSnat was performed in the yeast PJ69-4A (1.6.2) to generate the plasmid p5'sci1gfp.

A further construct was constructed in the pRSnat background containing the 5' flanking region of *sci1* and the *sci1* gene fused to the *Dsred* sequence. The 5' flanking region together with the *sci1* ORF was amplified with the primer pair *rud3\_5'f/sci1dsRed\_r* (1875 bp) using *S. macrospora* gDNA as template. The *Dsred* sequence fused to the *trpC* terminator sequence of *A. nidulans* was amplified with the primer pair DsRed-f/pRS426GFPprev (1466 bp) from pRHN1. Both fragments were homologously recombined (1.6.2) with the *XhoI* hydrolyzed pRSnat vector generating plasmid p5'sci1Dsred.

Also, *sci1-egfp* or *sci1-Dsred* fusion gene constructs under the control of the *ccg1* promoter of *N. crassa* were created. The *ccg1* promoter sequence was amplified from pHAN1 with the primer pair pRSccg1/Pccg1-r generating a 29 bp overhang to pRSnat. The *sci1* ORF was amplified with the primer pair *sci1ccg1\_f/sci1gfp\_r* or with *sci1ccg1\_f/sci1dsRed\_r* from *S. macrospora* gDNA and had overhangs to the *ccg1* promoter sequence and to the *egfp* or to the *Dsred* sequence, respectively. The *egfp* fused to the *trpC* terminator of *A. nidulans* was amplified using the plasmid p1783-1 (1510 bp) and *Dsred* fused to *trpC* was amplified from pRHN1 with the primer pairs GFP-f/pRS426GFPprev and DsRed-f/pRS426GFPprev (1466 bp), respectively producing 29 bp overhangs to pRSnat. The respective fragments were homologously recombined with the *XhoI* hydrolyzed pRSnat vector in the yeast PJ69-4A (1.6.2).

The obtained plasmids psci1gfp and psci1Dsred were transformed into *E. coli* (1.6.8.5) and were verified by sequencing (1.6.8.10). The respective plasmids were transformed into  $\Delta sci1_{hyg}$  (2.2.2) and hygromycin and nourseothricin resistant strains were selected. The strains,  $\Delta sci1_{hyg}::5'sci1egfp$ ,  $\Delta sci1_{hyg}::5'sci1Dsred$ ,  $\Delta sci1_{hyg}::sci1egfp$  and  $\Delta sci1_{hyg}::sci1Dsred$  were generated (Table 2).

##### 1.6.4.2 Construction of plasmids containing fragments of *sci1* and transformation into *S. macrospora*

Plasmids containing *sci1* fragments were generated for complementation studies in the sterile  $\Delta sci1_{hyg}$  background. All fragments were set under the control of the endogenous *sci1* promoter

## Materials and Methods

and were fused to the *egfp-trpC* sequence. The endogenous promoter of *sci1* was amplified from p5'sci1gfp using the primer pair rud3\_5'f/5'sci1\_rev and had an 29 bp overhang to the pRSnat plasmid. The *sci1* fragments were amplified from p5'sci1gfp with the primer pairs shown in table 6 generating 29 bp overhangs to the 5' flanking region of *sci1* and to the *egfp* sequence.

The *egfp-trpC* sequence (1510 bp) was amplified from p1783-1 with the primer pair GFP-f/pRS426GFPprev containing an 29 bp overhang to pRSnat. All three fragments, the 5' flanking region of *sci1*, the respective *sci1* fragment the *egfp-trpC* sequence and the *XhoI* hydrolyzed plasmid vector were cotransformed into PJ69-4A. The plasmids psci1<sub>63-207</sub>\_nat, psci1<sub>121-207</sub>\_nat, psci1<sub>121-298</sub>\_nat and psci1<sub>208-298</sub>\_nat (Table 3, Table 6) were generated by homologous recombination in PJ69-4A (1.6.2).

**Table 6: Overview of primer pairs used to amplify fragments of *sci1* and pRSnat plasmids generated**

Forward primer	Reverse primer	Amplified <i>sci1</i> fragment	Fragment size in bp	Plasmid backbone / enzyme used for hydrolysis	Constructed plasmid
sci1_t1f	sci1_t7r	sci1 <sub>63-207</sub>	437	pRSnat/ <i>XhoI</i>	psci1 <sub>63-207</sub> _nat
sci1_t3f	sci1_t7r	sci1 <sub>121-207</sub>	260	pRSnat/ <i>XhoI</i>	psci1 <sub>121-207</sub> _nat
sci1_t3f	sci1gfp_r	sci1 <sub>121-298</sub>	533	pRSnat/ <i>XhoI</i>	psci1 <sub>121-298</sub> _nat
sci1_t5f	sci1gfp_r	sci1 <sub>208-298</sub>	272	pRSnat/ <i>XhoI</i>	psci1 <sub>208-298</sub> _nat

The numbers given in the amplified fragment represent the amino acids of *sci1* encoded in the generated fragments

Plasmids were transformed into *E. coli* (1.6.8.5) and verified by sequencing (1.6.8.10) before they were used to transform  $\Delta$ sci1<sub>hyg</sub>. *S. macrospora* strains were transformed (2.2.2) with plasmids containing *sci1* fragments and hygromycin and nourseothricin clones were selected. The generated strains are listed in table 2.

### 1.6.5 Transformation of wt *S. macrospora* strains with pHA\_nat and pFLAG\_nat

The *ccg1* sequence fused to the *ha*-sequence (981 bp) was amplified from the plasmid pHAN-1 with the primer pair pRSccg1/Pccg1HAr\_TtrpC containing 29 bp overhangs to the pRSnat vector and to the *trpC*-sequence. The terminator sequence *trpC* (768 bp) was amplified from the plasmid p1783-1 with the primer pair TrpC\_F/pRS426GFPprev containing a 29 bp overhang to the pRSnat plasmid. Both amplicons were cotransformed with the *XhoI* hydrolyzed pRSnat plasmid into the yeast strain PJ69-4A for homologous recombination (1.6.2).

The *ccg1-flag*-sequence (1017 bp) was amplified from the plasmid pFLAGN1 using the primer pair pRSccg1/Pccg1FLAGr\_TtrpC. The fragment contained an 29 bp overhang to the pRSnat vector and the *trpC*-sequence. The *trpC* sequence (768 bp) amplified from plasmid p1783-1 with the primer pair TrpC\_F/pRS426GFPprev contained an overhang (29 bp) to the pRSnat plasmid. The two fragments and the *XhoI* hydrolyzed pRSnat plasmid were homologously recombined in PJ69-4A.

The successfully generated plasmid pHA\_nat or pFLAG\_nat were transformed into wild type *S. macrospora* strain (2.2.2) and nourseothricin resistant strains wt::ha or wt::flag were selected, respectively. The strains were used as negative controls for HA- or FLAG pull-downs coupled to LC/MS (Table 8).

### 1.6.6 Generation of expression plasmids for complementation attempts of *S. macrospora* with the mammalian FGFR1OP2 and yeast Far3 and Far7

Lentivirus-derived plasmids pRRLsinhCMV-IG containing Rat *Fgfr1op2* (644 bp), human wt *FGFR1OP2* (758 bp) and human single nucleotide polymorphism 1 (SNP1) *FGFR1OP2* (*FGFR1OP2\_SNP1*) (758 bp) genes derived from cDNA were kindly donated by Prof. D.M.D. Ichiro Nishimura (Lin *et al.*, 2010). The mammalian *FGFR1OP2* genes are highly conserved and genes from human and rat were amplified with the primer pair FG\_RNf/FG\_RNr. The *ccg1* promoter (921 bp) was amplified from pHAN1 with the primer pair Pccg1/ccg1\_FGRN containing overhangs to the pRSnat vector and the *FGFR1OP2* genes.

The *ha*-tag sequence fused to the *trpC* terminator (819 bp) was amplified with the primer pair HAF\_FGRN/pRS426GFPreV from plasmid pHA\_nat and contained 29 bp overhangs to the *FGFR1OP2* genes and the pRSnat plasmid. The fragments *pccg1*, *FGFR1OP2s* and *HA-trpC* were homologously recombined with the *XhoI* hydrolyzed pRSnat vector in PJ69-4A (1.6.2) and three plasmids pPcFGwtRN, pPcFGwtHsHs, pPcFGSNP1 were generated (Table 3), transformed into *E. coli* and sequenced (1.6.8.5, 1.6.8.10). The plasmids pPcFGwtRN, pPcFGwtHsHs, pPcFGSNP1 were isolated from *E. coli* and transformed into  $\Delta$ sci1<sub>hyg</sub> (2.2.2) generating the nourseothricin and hygromycin resistant strains,  $\Delta$ sci1<sub>hyg</sub>::Rnfgfr1op2,  $\Delta$ sci1<sub>hyg</sub>::Hsfgfr1op2 and  $\Delta$ sci1<sub>hyg</sub>::Hsfgfr1op2SNP1.

*S. cerevisiae* FAR3 and FAR7 genes were amplified with the primer pairs Far3\_f/Far3\_r (662 bp) and Far7\_f/Far7flag\_r (622 bp) with overhangs to *ccg1* and *ha-trpC* or *flag-trpC*, respectively. *S. cerevisiae* PJ69-4A genomic DNA was used as template. The *ha-trpC* or *flag-trpC* sequence were amplified from the plasmids pHA\_nat or pFLAG\_hyg, using the primer pairs HAF/pRS426GFPreV (819 bp) or FLAGf/pRS426GFPreV (852 bp), respectively containing an overhang to pRSnat. Homologous recombination of *ccg1*, FAR3 or FAR7, *HA-trpC* or *FLAG-trpC*, respectively and *XhoI* hydrolyzed pRSnat was performed in PJ69-4A (2.2.2) and the plasmids pFar3HA and pFar7FLAG were generated. The  $\Delta$ sci1<sub>hyg</sub> strain was transformed (2.2.2) with pFar3HA or pFar7FLAG and nourseothricin and hygromycin resistant strains  $\Delta$ sci1<sub>hyg</sub>::FAR3 and  $\Delta$ sci1<sub>hyg</sub>::FAR7 were selected.

### 1.6.7 Generation of *S. macrospora* strains expressing fluorescent fusion proteins

#### 1.6.7.1 Complementation of the $\Delta$ sci1<sub>hyg</sub> $\Delta$ pro11 strain

The  $\Delta$ sci1<sub>hyg</sub> $\Delta$ pro11 strain was cotransformed with the plasmids psci1Dsred and pHAPRO11GFP (2.2.2) and nourseothricin and hygromycin resistant strains were selected. The resulting strain  $\Delta$ sci1<sub>hyg</sub> $\Delta$ pro11::sci1Dsred+hapro11egfp became fertile indicating that both constructs were functional.

### 1.6.7.2 Generation of *S. macrospora* strains for analysis of nuclei, mitochondria, ER, actin, nuclear envelope as well as early and late endosomes with fluorescence microscopy

For generation of the plasmid pRH2B\_nat, the *h2b-tdTomato* construct under the control of the *gpd* promoter and the *trpC* terminator of *A. nidulans* were amplified with the primer pair pRS426GFPprev/ pRS426GPDF2 (3785 bp) from pRH2B. The fragment was homologously recombined (2.2.2) with the *XhoI* hydrolyzed pRSnat plasmid in the yeast PJ69-4A. The pRH2B\_nat was transformed into *E. coli* and verified by sequencing (2.2.8.5, 2.2.8.10).

The wt *S. macrospora* strain and the  $\Delta$ sci1<sub>hyg</sub> strain each were transformed with the plasmids pRH2B\_nat (nuclei) or pMito-DsRED (mitochondria), or pAL-lifeact (actin) or pDsREDKDEL (ER) and nourseothricin or hygromycin and nourseothricin resistant strains, respectively were selected (2.2.2). Also, wt *S. macrospora* and  $\Delta$ sci1<sub>nat</sub> were transformed with pHEgfpRab5 (early endosomes) and pHEgfpRab7 (late endosomes) and hygromycin as well as hygromycin and nourseothricin resistant strains, respectively were selected (2.2.2). The strains generated and used for fluorescence microscopy are listed in table 2.

### 1.6.7.3 Generation of SmpPOM152 expression plasmid for transformation into *S. macrospora*

The *Smpom152* gene (SMAC\_03501) was amplified from genomic *S. macrospora* DNA with the primer pair Pom\_ccgf/Pom\_gfpr (3916 bp) and contained 29 bp overhangs to the *ccg1* promoter. The *ccg1* promoter (921 bp) was amplified with the primer pair pRSccg1/ccg1-r from pHAN-1 containing an 29 bp overhang to *egfp*. The *egfp-trpC* fragment (1510 bp) was amplified from p1783-1 containing an overhang (29 bp) to the pRSnat plasmid. All generated fragments were cotransformed into PJ69-4A for homologous recombination (2.2.2) with *XhoI* hydrolyzed pRSnat and the plasmid pSmpPOM152 was generated. The plasmid pSmpPOM152 was transformed into *E. coli* and verified by sequencing (2.2.8.5, 2.2.8.10). Finally, pSmpPOM152 was transformed into the wt and into  $\Delta$ sci1<sub>hyg</sub> (2.2.2) and nourseothricin and nourseothricin/hygromycin resistant strains were selected generating the strains wt::Smpom152egfp and  $\Delta$ sci1<sub>hyg</sub>::Smpom152egfp (Table 2).

### 1.6.7.4 Generation of $\Delta$ pro11::hapro11egfp strain

The *S. macrospora*  $\Delta$ pro11 strain was transformed (2.2.2) with the pHAPRO11GFP plasmid encoding the *pro11* gene under the control of the *ccg1* promoter and the *trpC* terminator and fused to the *ha* and *egfp* sequence. Hygromycin and nourseothricin resistant strains were selected and complemented the sterile phenotype indicating that the *hapro11egfp* construct is functional generating the strain  $\Delta$ pro11::hapro11egfp (Table 2).

## 1.6.8 Molecular biology methods: nucleic acids

### 1.6.8.1 PCR

DNA fragments were amplified from gDNA, complementary DNA or plasmids using polymerase chain reaction (PCR) (Mullis & Fallona, 1987). For the PCR reaction 50-100 ng of DNA were used. *E. coli* colony PCR was performed in volumes of 12.5  $\mu$ L using the *E. coli* culture as DNA source. The

## Materials and Methods

PCR was performed as suggested by the enzyme manufacturer. The melting temperature of the primers was adjusted as required for the oligonucleotides. PCR samples were shortly stored at 4°C or for long term storage at -20°C. Components used for the standard 50 µL PCR reactions were as follows:

<b>Phusion Polymerase</b>		<b>TopTaq Polymerase</b>	
Sterile H <sub>2</sub> O <sub>dest</sub>	up to 50 µL	Sterile H <sub>2</sub> O <sub>dest</sub>	up to 50 µL
5 x HF-buffer	10 µL	10 x TopTaq PCR buffer	5 µL
10 mM dNTPs	1 µL	10 mM dNTPs	1 µL
10 pM Primer 1	1 µL	10 pM Primer 1	1 µL
10 pM Primer 2	1 µL	10 pM Primer 2	1 µL
Template DNA	50-100 ng	Template DNA	<1 µg/reaction
DMSO	1.5 µL	TopTaq	0.25 µL
Phu Polymerase	0.5 µL		

### 1.6.8.2 Separation of nucleic acids with agarose-gel electrophoresis

DNA fragments were mixed with 6x loading dye loaded on 1% or 2% 1 x TBE agarose gels and separated in a horizontal Mupid one (Biozym Scientific GmbH, Germany) gel electrophoresis chamber in 0.5% TBE buffer applying 100-130 V (Sambrook *et al.*, 2001).

The GeneRuler™ DNA Ladder Mix (Thermo Scientific, SM0331) or the GeneRuler™ 1kb DNA Ladder (Thermo Scientific, SM0313) were used as marker for DNA fragment size. The DNA was stained for 10-20 min in a 1 µg/mL ethidium bromide solution.

RNA samples were mixed with 2x RNA buffer followed by incubation for 10 min at 65°C. Ribonucleic acids were separated in an agarose gel containing 1.2% 1x MOPS and 5% formaldehyde and immersed in 1x MOPS buffer at 80-100 V in a gel electrophoresis chamber. The GeneRuler™ 1kb DNA Ladder (Thermo Scientific, SM0313) was used as marker for RNA fragment size.

DNA and RNA were visualized by UV light and documented with the BioDocAnalyzer (Biometra, Germany).

### 1.6.8.3 Purification of nucleic acids

#### Isolation of DNA from agarose gels

DNA from agarose gels was isolated with the "QIAquick Gel Extraction" kit as described by the manufacturer.

#### Dialysis of aqueous solutions/purification of PCR products

Dialysis of plasmids or amplicons for *S. cerevisiae* transformation was performed with dialysis filters. Eighteen microliter of aqueous plasmid solution were applied on the dialysis filters (Merck Millipore, Germany) placed onto sterile H<sub>2</sub>O<sub>dest</sub> at room temperature and were removed after 20 min. PCR products were alternatively purified with the "QIAquick PCR purification kit" as described by the manufacturer.

#### 1.6.8.4 Hydrolysis and ligation of nucleic acids

##### Hydrolysis of plasmids

Hydrolysis of plasmids was performed with 1 U restriction endonuclease per  $\mu\text{g}$  of DNA in 10-20  $\mu\text{L}$  volumes (37°C for 2 hours). Hydrolysis was performed in buffer solutions as suggested by the manufacturer.

##### Dephosphorylation of plasmids and ligation

Vectors for ligation were hydrolysed as described before and subsequently dephosphorylated with the “Rapid DNA Dephos & Ligation kit” as suggested by the manufacturer and ligation was performed with the T4 DNA ligase as described by the manufacturer.

#### 1.6.8.5 Isolation of plasmid DNA from *E. coli*

For plasmid DNA isolation mini- and midi- preparation was used applying the “FastGene® Plasmid Mini kit” as described by the manufacturer or was performed according to Birnboim and Doly (1979).

#### 1.6.8.6 Isolation of plasmid DNA from *S. cerevisiae*

*S. cerevisiae* colonies on SD-Ura plates were washed down from the plates with sterile  $\text{H}_2\text{O}_{\text{dest}}$ . For the isolation of plasmid DNA from *S. cerevisiae* the “ZR Fungal/Bacterial DNA MiniPrep™ kit” was applied as suggested by the manufacturer.

#### 1.6.8.7 Isolation of RNA and genomic DNA from *S. macrospora*

For RNA and gDNA isolation, *S. macrospora* mycelium was grown for 3 days at 27°C in liquid BMM, harvested, dried by pressing and grounded to powder in a mortar with the help of liquid nitrogen.

##### Isolation of RNA

RNA was isolated from *S. macrospora* as described by Elleuche and Pöggeler (2009). One milliliter trizol was added to the pulverized mycelium followed by centrifugation for 10 min at 13,000 rpm. The supernatant was mixed with 200  $\mu\text{L}$  chloroform in a new tube followed by centrifugation for 10 min at 13,000 rpm. The supernatant was mixed with the same amount of ice-cold isopropanol. The RNA was incubated for 10 min at RT, centrifuged again and washed with 70% ice-cold ethanol. The RNA was dried under the hood, combined with 120  $\mu\text{L}$  water and solved at 1000 rpm for 30 min at 60 °C.

##### Isolation of genomic DNA (gDNA)

E-cups (2 mL) were filled to 1/3 with nitrogen grounded mycelium and 600  $\mu\text{L}$  lysis buffer was added followed by vortexing and 30 min incubation at 70°C. The gDNA was isolated according to the phenol-chloroform extraction method (Brawerman *et al.*, 1972, Kirby, 1956, Pöggeler *et al.*, 1997). Alternatively, gDNA from *S. macrospora* was isolated for PCR amplification using a modified sodium acetate/isopropanol protocol (Cenis, 1992). Mycelium was press dried in 2 mL tubes, frozen at -80°C, supplemented with 6  $\emptyset$  2.85-3.45 mm glass beads, combined with 300  $\mu\text{L}$  lysis buffer and

homogenized for 5 min with 30 Hz in the Qiagen Retsch® TissueLyser (Qiagen Retsch GmbH, Germany). Samples were incubated for 30 min at 70°C, 200 µL 3 M sodium acetate (pH 5.2) was added followed by 10 min incubation at -80°C. Samples were centrifuged 10 min (13,000 rpm) at RT and the supernatants were combined with the same amount of isopropanol. After incubation for 10 min at RT, samples were again centrifuged (10 min, 13,000 rpm), the supernatant was discarded and the pellet was washed with 300 µL 70% ethanol, followed by 2 min centrifugation at 13,000 rpm.

The gDNA was dried under the hood, dissolved in sterile H<sub>2</sub>O<sub>dest</sub> and stored at 4°C, for short-term storage or at -20°C, for long-term storage.

### 1.6.8.8 Southern blotting and hybridization

In locus-deletion of genes and insertion of a resistance cassette was verified by Southern blot (Southern, 1975). Genomic DNA (30-50 µg) was hydrolyzed with the respective enzymes in a 50 µL reaction volume. The hydrolyzed gDNA was separated on a 1% agarose gel at 100 V. The agarose gel was washed for 10 min in Southern blot buffer I, 25 min in Southern blot buffer II and finally in Southern blot buffer III for 30 min. The DNA was blotted for 2-3 h onto a Amersham Hybond™ -N<sup>+</sup> membrane. The membrane was dried (7 min/70°C) and DNA was cross-linked by exposure to UV-light (3 min each side of the membrane).

The DNA for the probe for *sci1* was generated with the primer pair *sosci1\_f/sosci1\_r* (650 bp) and purified with the “QIAquick gel extraction kit”. 100 ng of the specific probe and 1 µL of 1:1000 diluted GeneRuler™ 1 kb DNA Ladder were labeled with the “AlkPhos Direct Labelling and Detection Kit”. The detection was performed as described by the manufacturer’s manual.

### 1.6.8.9 Synthesis of cDNA and qRT-PCR

*S. macrospora* wt was grown in liquid BMM for 3, 4, 5, 6 and 7 days at 27 °C, in floating cultures for sexual reproduction conditions and in shaking (130 rpm) Erlenmeyer flasks filled with 100 µL BMM for vegetative conditions (Nowrousian & Cebula, 2005). RNA was isolated as described in 1.6.8.7 “Isolation of RNA”. The quantitative reverse-transcription PCR was performed two times with independent biological samples in triplicates. The qRT-PCR was performed as described before and the Mastercycler® ep realplex (Eppendorf, Hamburg, Germany) was used (Elleuche & Pöggeler, 2009). The primer pair RTsci1f/RTsci1r amplified a 236 bp from *sci1*. Primer combination SSU-f/SSU-r resulted in the amplification of a 180 bp fragment coding for the small rRNA subunit of *S. macrospora*, which was used as a reference for the normalization of Ct values. The significance of the qRT-PCR results was calculated with the software tool REST© (Pfaffl *et al.*, 2002).

#### **1.6.8.10 Synthesis of oligonucleotides and sequencing**

Oligonucleotides were synthesized by Eurofins MWG Operon (Ebersberg, Germany). The primers are presented in table 4. Sequencing of DNA was performed by the Göttinger Genom Labor (G2L) (Georg-August University of Göttingen, Germany) or by Seqlab (Sequence Laboratories Göttingen GmbH, Germany). Sequences were analyzed with the help of the software Chromas Lite 2.01 (1998-2005 Technelysium Pty Ltd). The Nucleotide BLAST search tool (Altschul *et al.*, 1990) (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>) was used to compare the sequenced plasmid/DNA with the sequences of the plasmids or the predicted gDNA/cDNA sequences.

#### **1.6.9 Molecular biology methods: proteins**

##### **1.6.9.1 Isolation of proteins from *S. macrospora***

*S. macrospora* mycelium was harvested, pressed dried between paper towels and ground in liquid nitrogen. One gram of mycelium was combined with 500  $\mu$ L GFP-Trap lysis buffer and centrifuged at 16.000 *g* for 30 min. The supernatant was centrifuged again at 16.000 *g* for 30 min and the supernatant was transferred to a new tube.

Protein extracts for Western blot were combined with the appropriate amount of 5 x protein loading dye or with the NuPAGE™ LDS Sample Buffer (4x) supplemented with DTT, boiled for 10 min at 98°C (Laemmli, 1970) or for 10 min at 70°C, respectively and 20-30  $\mu$ L were used for SDS-PAGE.

For the pull-downs, GFP-Trap\_A beads (anti-GFP V<sub>H</sub>H coupled to agarose beads) were used to bind eGFP fusion proteins. GFP-Trap\_A beads were washed three times with 350  $\mu$ L ice-cold GFP-Trap dilution buffer (centrifugation 2 min, 3000 rpm, 4°C).

Supernatants containing FLAG fusion proteins were incubated with the respective antibody for 2 h on a rotation device (4°). Protein A Sepharose™ CL-4B beads or anti-HA-agarose beads were equilibrated with GFP-Trap dilution buffer, 10 mg beads were incubated for 30 min with 350  $\mu$ L ice-cold GFP-Trap dilution buffer followed by 2 washing steps (centrifugation 2 min, 3000 rpm, 4°C). The antibody-antigen complex was bound to Protein A Sepharose™ CL-4B for 1 h on a rotation device (4°).

For the pull-downs 1 mL of the supernatant or of the antibody-antigen complex was incubated with GFP-Trap\_A, anti-HA-agarose beads or Protein A Sepharose™ CL-4B beads, on a rotating device for 3 h or 1 h at 4°C, respectively. The beads were washed twice with 500  $\mu$ L GFP-Trap dilution buffer containing 1 mM PMSF and EDTA-free protease inhibitor cocktail. Washing buffer was removed and samples were boiled with the appropriate amount of 5x protein loading dye for 10 min at 98°C and 20-30  $\mu$ L were used for SDS-PAGE.

##### **1.6.9.2 Determination of protein concentration**

Protein concentration was measured using the Bradford assay (Bradford, 1976). The protein sample (10  $\mu$ L) was mixed with 1x Roti®-Quant reagent (990  $\mu$ L) and the absorption was determined

at 595 nm in a “Libra S12” (biochrom, UK) spectrophotometer in a 1 mL disposable cuvette after incubated for 2 min at RT. For generation of a standard curve bovine serum albumin was used.

### 1.6.9.3 SDS-PAGE

Proteins were separated according to their size by SDS-PAGE (Laemmli, 1970). With the help of “Mini-PROTEAN® Tetra Cell” (Bio-Rad, Germany) SDS-gels (Table 7) were prepared. Protein samples were mixed with the protein loading dye or with the protein loading dye or the NuPAGE™ LDS sample buffer supplemented with DTT were loaded into pockets of SDS gels immersed in SDS-PAGE-running buffer. Proteins were separated with SDS-PAGE at 130 V. Five microliter of the Pageruler™ Prestained Protein Ladder were used as protein standard.

**Table 7: Recipes for stacking and resolving polyacrylamide gels**

Component	Stacking Gel (5% Acrylamide)	Resolving Gel (12% Acrylamide)	Unit
<b>Rotiphorese Gel30 (Roth, Karlsruhe)</b>	0.250	2.800	ml
<b>1.5M Tris/HCl, pH8,0</b>	-	1.750	ml
<b>0.5M Tris/HCl, pH 6,5</b>	0.375	-	ml
<b>20% (w/v) SDS</b>	7.500	37.000	µl
<b>H<sub>2</sub>O<sub>dest.</sub></b>	0.860	2.350	ml
<b>TEMED</b>	1.300	5.700	µl
<b>10% (w/v) APS</b>	10.000	56.000	µl

### 1.6.9.4 Western blotting

Western blot analysis was used to detect fusion proteins by an antigen-antibody reaction. Proteins separated in SDS-PAGE were transferred to a Amersham™ Protran™ Nitrocellulose Blotting Membrane applying 200 mA a semi-dry device (Biometra, Germany) (Towbin *et al.*, 1979). The membrane was washed once with TBST buffer for 20 min and blocked with 5% (w/v) milk powder in TBST for 1 h at RT. Antigen-antibody reaction was performed using a horse-radish peroxidase (HRP) coupled GFP-antibody or a specific primary antibody (Table 5) solved in 5% skim milk/TBST. The membrane and the antibody solution were incubated over night at 4°C. After the antibody was removed the membrane was washed three times for 20 min with TBST. If required the respective secondary antibody was applied to the membrane for 1 h at RT and the membrane was again washed three times with TBST. Enhanced chemiluminescent reaction was used to detect the HRP coupled antibodies using the Immobilon™ Western HRP Substrate kit (Haan & Behrmann, 2007).

### 1.6.9.5 Coomassie staining of polyacrylamide gels

Proteins resolved on SDS-Gels were stained with Coomassie® Brilliant Blue R250 (Wilson, 1979). SDS-Gels were fixed for 30 minutes in the decolorizer I solution. Coomassie stain Stock I containing

## Materials and Methods

100 mg Brilliant Blue R solved in 50 mL of 90% ethanol was mixed 1:1 with Coomassie stain Stock II and SDS-gels were stained for 20 min under continuous gentle agitation. Stained gels were washed for 5 min in the decolorizer I solution. Further, washing and removing of Coomassie® Brilliant Blue R250 was performed in several wash steps with decolorizer II solution. The SDS-gels were destained in several steps, three times for 20 min and over night. If required gels were again destained for 20 min and were finally washed two times (5 min) in H<sub>2</sub>O<sub>dest.</sub> Each lane was cut out and further cutted into 10 pieces for the trypsin digest.

### 1.6.9.6 Trypsin digest, stage tipping and sample preparation

Trypsin digest was performed to prepare protein samples for LC/MS (Shevchenko *et al.*, 1996). In-gel digestion with trypsin was performed for each SDS-Gel piece separately in 1.5 mL Protein LoBind Tubes.

Acetonitrile (40 µL) was added to fully cover the gel pieces. Samples were incubated for 10 min under constant shaking, and acetonitrile was removed. Gel pieces were dried for 10 min in the Eppendorf concentrator 5301 (Eppendorf, Germany) and 150 µL 10 mM DTT/100 mM NH<sub>4</sub>HCO<sub>3</sub> was added followed by incubation for 1 h at 56°C. After the DTT/ NH<sub>4</sub>HCO<sub>3</sub> solution was removed, gel pieces were supplemented with 150 µL 55 mM iodoacetamide/100 mM NH<sub>4</sub>HCO<sub>3</sub>. Samples were incubated for 45 min (RT) in the dark with occasional vortexing and iodoacetamide was removed. Gel pieces were washed with 150 µL 100 mM NH<sub>4</sub>HCO<sub>3</sub> first and second with 150 µL acetonitrile (each 10 min incubation). Washing with 100 mM NH<sub>4</sub>HCO<sub>3</sub> and acetonitrile was repeated two times more. Washed gel pieces were dried in the Eppendorf concentrator 5301 for 10 min and covered with sufficient trypsin digest buffer. After incubation on ice for 45 min, excessive trypsin digest buffer was removed and 25 mM NH<sub>4</sub>HCO<sub>3</sub>, was added followed by incubation at 37°C over night. Samples were centrifuged at 13,000 rpm and the liquid was transferred to a fresh 1.5 ml Protein LoBind Tube. In the next steps peptides were eluted from gel pieces and collected in 1.5 ml Protein LoBind Tubes. To extract the peptides from gel pieces 40 µL of 20 mM NH<sub>4</sub>HCO<sub>3</sub> was added and the samples were incubated for 10 min. The liquid removed from the gel pieces was collected. An acetonitrile (50%)/5% formic acid mixture was added to the gel pieces followed by 20 min incubation. Again the liquid was collected and elution was performed twice more. For the pull-downs the eluates of the five upper and the five lower pieces (of one lane) were combined and for the negative controls, peptides from all 10-gel pieces were pooled. The collected liquid was dried in the Eppendorf concentrator 5301.

Purification of peptides was performed with the C18 stop and go extraction (stage) tips according to (Rappsilber *et al.*, 2003) and (Rappsilber *et al.*, 2007). Two small disks were punched out from an Empore™ Solid Phase Extraction (SPE) Disk C18/47mm with a 16 gauge, Metal Hub Needle (Hamilton, USA, 7748-02) and pushed into a 100-200 µL pipette tips. Equilibration of the C18 column was performed with 100 µL methanol/0.1% formic acid, followed by 100 µL 70% acetonitrile/0.1% formic acid and washed twice with 100 µL H<sub>2</sub>O/0.1% formic acid. Each centrifugation step was performed with the help of an adaptor in 2 ml reaction tubes at 13,000 rpm for 2 min.

## Materials and Methods

Peptides were solved in 20 µl LC/MS sample buffer (H<sub>2</sub>O/2% acetonitrile/0.1% formic acid) and applied to the stage tips. Samples were centrifuged at 4000 rpm for 5 min and the flow-trough was applied once more on the stage tip to increase the yield. Washing was performed twice with 100 µl H<sub>2</sub>O/0.1% formic acid, each time followed by centrifugation at 10,000 rpm for 2 min. Peptides were eluted with 60 µl 70% acetonitrile with 0.1% formic acid (centrifugation 5 min, 4000 rpm). Peptide solution was dried in the Eppendorf concentrator 5301 and peptides were solved in 20 µl fresh LC/MS sample buffer.

The eluted peptide samples were analyzed by LC/MS (Hellman *et al.*, 1995, Speicher *et al.*, 2000). Each pull-down and LC/MS was performed in three biological replicates resulting in data from LC/MS1, LC/MS2 and LC/MS3. PRO11 or SmMOB3 pull-downs and LC/MS were performed in parallel. SCI1eGFP pull-down and LC/MS was also performed in three biological replicates (Table 8).

**Table 8: Data from PRO11, SmMOB3 and SCI1 pull-down experiments coupled to LC/MS**

Pull-down/LC/MS	Bait	Designation	Negative control	Designation
1	HAPRO11	ER36-37	HA	ER34-35
1	HAPRO11eGFP	ER33	GFP	ER32
2	HAPRO11	ER44-45	HA	ER46-47
2	HAPRO11eGFP	ER49	GFP	ER48
3	HAPRO11	ER66-67	HA	ER62-63
3	HAPRO11eGFP	ER65	GFP	ER64
1	FLAGSmMOB3	ER40-41	FLAG	ER42-43
1	SmMOB3eGFP	ER39	GFP	ER38
2	FLAGSmMOB3	ER54-55	FLAG	ER50-51
2	SmMOB3eGFP	ER53	GFP	ER52
3	FLAGSmMOB3	ER60-61	FLAG	ER56-57
3	SmMOB3eGFP	ER59	GFP	ER58
1	SCI1eGFP	ER70-71	GFP	ER68-69
2	SCI1eGFP	ER74-75	GFP	ER72-73
3	SCI1eGFP	ER78-79	GFP	ER76-77

The number of pull-downs and LC/MS experiments is given. For each pull-down coupled to LC/MS a corresponding negative control was prepared. Designation of LC/MS data derived from baits and the negative controls are presented.

### 1.6.9.7 Liquid chromatography-mass spectrometry analyses

Liquid chromatography-mass spectrometry analysis was performed by the Mass Spectrometry - Yeast group, Dr. Oliver Valerius (Institute of Microbiology and Genetics Department of Molecular Microbiology & Genetics, Prof. Dr. Gerhard Braus, Göttingen). Proteins were identified by LC-MS with an Orbitrap Velos Pro™ Hybrid Ion Trap-Orbitrap mass spectrometer. Peptide solutions (1-5 µl) were loaded and washed on an Acclaim® PepMAP 100 pre-column (#164564, 100 µm x 2 cm, C18, 3µm, 100 Å, Thermo Fisher Scientific) with 100% loading solvent A (98% H<sub>2</sub>O, 2% acetonitrile, 0.07% trifluoroacetic acid (TFA)). The flow rate was 25 µl/min for 6 min. Reverse phase chromatography was applied to separate peptides on an Acclaim® PepMAP RSLC column (75 µm x 25 cm (#164536) or 50 cm (#164540), C18, 3 µm, 100 Å, Thermo Fisher Scientific) using a gradient from 98% solvent A (H<sub>2</sub>O, 0.1% formic acid) and 2% solvent B (80% acetonitrile, 20% H<sub>2</sub>O, 0.1% formic acid) to 42% solvent B for 95 min and to 65% solvent B for the following 26 min at a flow rate of 300 nl/min. Peptides eluting from the chromatographic column were on-line ionized by nanoelectrospray at 2.4 kV with the Nanospray Flex Ion Source (Thermo Fisher Scientific). Full scans of ionized peptides within a mass range of 300-1850 m/z were recorded with the Orbitrap FT analyzer at a resolution of 30,000. Collision induced dissociation (CID) fragmentation of data-dependent top-ten peptides was performed with the LTQ Velos Pro linear ion trap. For data acquisition and programming, the XCalibur 2.2 software (Thermo Fisher Scientific) was used.

### 1.6.10 Y2H and drop test

Yeast two-hybrid experiments (Fields & Song, 1989) were performed using the pGADT7 and pGBKT7 vector system in the *S. cerevisiae* PJ69-4A strain (James *et al.*, 1996).

Plasmids encoding *sci1* fragments fused to the BD sequence were generated. *S. macrospora* cDNA was used as template for amplification of the respective *sci1* fragments. The primer pairs for generation of the respective fragments containing 29 bp overhangs to pGBKT7 are summarized in table 9. For homologous recombination, the respective fragment presented in table 9 were cotransformed with *Pst*I hydrolyzed pGBKT7 into the yeast strain AH109 (2.2.2).

The *pro11* fragment encoding the AA region 1-110 of PRO11 needed to be cloned into the pGBKT7 background. The fragment was amplified from plasmid pBD-pro11(1-110) (401 bp) and inserted into the *Pst*I hydrolyzed pGBKT7 plasmid by homologous recombination in AH109 (2.2.2).

The AD plasmids containing the FAR genes were generated by ligation. *FAR3*, *FAR7* and *FAR8* were amplified from PJ69-4A gDNA. *FAR3* amplified with the primer pair Far3ph\_f/Far3\_r (662 bp) contained additional bp for hydrolysis with *Nde*I. *Nde*I hydrolyzed *FAR3* PCR product and pGADT7 were ligated to generate the plasmid pADFar3. *FAR7* was amplified with the primer pair Far7ph\_f/Far7flag\_r. The *FAR7* fragment (622 bp) was ligated into *Sma*I hydrolyzed pGADT7. *FAR8* was amplified with the primer pair Far8phf/Far8phr (1571 bp) and was also ligated into pGADT7 hydrolyzed with *Sma*I. Plasmids pADFar7 and pADFar8 were generated by blunt end ligation (2.2.8.4). All Y2H plasmids were transformed into *E. coli* and verified by sequencing.

**Table 9: Primer pairs used to amplify *sci1* fragments for generation of pGBKT7 plasmids encoding *sci1* fragments**

Forward primer	Reverse primer	Amplified fragment	Fragment size in bp	Hydrolyzed backbone	Enzyme for hydrolysis	Resulting plasmid
sci1_Y1f	sci1_Y1r	sci1 <sub>1-62</sub>	187	pGBKT	<i>Pst</i> I	pBDsci1 <sub>1-62</sub>
sci1_Y1f	sci1_Y2r	sci1 <sub>1-120</sub>	361	pGBKT	<i>Pst</i> I	pBDsci1 <sub>1-120</sub>
sci1_Y5f	sci1_Y5r	sci1 <sub>100-155</sub>	165	pGBKT	<i>Pst</i> I	pBDsci1 <sub>100-155</sub>
sci1_Y2f	sci1_Y3r	sci1 <sub>63-207</sub>	437	pGBKT	<i>Pst</i> I	pBDsci1 <sub>63-207</sub>
sci1_Y3f	sci1_Y3r	sci1 <sub>121-207</sub>	263	pGBKT	<i>Pst</i> I	pBDsci1 <sub>121-207</sub>
sci1_Y3f	sci1_Y4r	sci1 <sub>121-298</sub>	536	pGBKT	<i>Pst</i> I	pBDsci1 <sub>121-298</sub>
sci1_Y4f	sci1_Y4r	sci1 <sub>208-298</sub>	275	pGBKT	<i>Pst</i> I	pBDsci1 <sub>208-298</sub>

The numbers given in the amplicons represent the amino acids of *sci1* encoded in the corresponding generated fragments

The AD and BD plasmids were cotransformed into PJ69-4A generating the strains used for the Y2H drop tests. The yeast strains generated, the growth controls and the Y2H-drop testes are presented in figure 16, figure 19 and figure S 9, respectively.

The pGADT7 encodes the activation domain (AD) sequence and pGBKT7 encodes the binding domain (BD) sequence of the transcriptional activator *GAL4*. When the fusion proteins interact, Gal4 activates transcription of the reporter genes *HIS3* and *ADE2*, which allows synthesis of adenine and histidine and growth of PJ69-4A on SD medium without adenine and histidine (SD-Ade, -Trp). As a positive control and test of the system competency, yeast strains were transformed with plasmids encoding the AD fused to the Gal4-BD interacting protein RanBPM (Tucker *et al.*, 2009) and BD fused to SCI1, PRO11 or PRO45 protein fragments. For the negative controls, yeast strains containing empty plasmids pGADT7 or pGBKT7 and corresponding *sci1*, *pro11* or *pro45* fragments fused to the BD or AD sequence (respectively) were used (James *et al.*, 1996). A drop test was performed and yeast growth was observed on synthetic defined (SD) medium without leucine (Leu), tryptophan (Trp), adenine (Ade) and histidine (His) (-Leu/ Trp/ Ade/ His, -Leu/ Trp/ Ade, -Leu/ Trp/ His and -Leu/ Trp). To do this, yeast strains were grown in liquid SD -Leu/-Trp to log phase and were diluted to an OD<sub>600</sub> of 0.1. The 0.1 dilution and a 1:10 dilution series (of each 20 µL) were spotted onto selective SD medium. Yeasts were incubated for 3 days at 30 °C and pictures were taken with the BioDocAnalyzer (Biometra, Germany).

### 1.6.11 Analytical methods

#### 1.6.11.1 Light and fluorescence microscopy

For light microscopy the Axiolmager M1 microscope (Zeiss, Jena, Germany) was used. The images were taken with the Photometrics CoolSNAP HQ2 camera (Roper Scientific, Photometrics, Tucson, Arizona) and were edited with MetaMorph (version 6.3.1; Universal Imaging).

#### Investigation of sexual structures

For the investigation of sexual structures, strains were grown for 2-8 days and documented with differential interference-contrast (DIC) microscopy. All *S. macrospora* strains were grown on BMM covered glass slides and 2 mL liquid BMM was put on top.

#### Investigation of hyphal fusion events

For investigation of hyphal fusion events with DIC microscopy, strains were grown on cellophane-covered minimal medium containing soluble starch (MMS) plates for 3 days at 27°C (Rech *et al.*, 2007).

#### Counting of protoperithecia

Wild type,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$  strains were grown on BMM covered slides and DIC microscopy was used to count protoperithecia with a size of 40-200  $\mu m$ . The fast growing wt was grown for 5 days,  $\Delta sci1_{hyg}::5'sci1egfp$  (partially complemented) was grown for 6 days and the  $\Delta sci1_{hyg}$  strain, which shows a very slow growth phenotype was grown for 7 days. For the three strains, similar regions for protoperithecia counting were defined. Protoperithecia were counted 5 cm away from the inoculated agar piece for wt and 4 cm for the  $\Delta sci1_{hyg}::5'sci1egfp$  strain. Protoperithecia in the  $\Delta sci1_{hyg}$  strain were counted 3 cm away from the inoculated agar piece. One  $cm^2$  of mycelium of each strain was used to count protoperithecia in five independent experiments (n=5).

#### Documentation of *S. macrospora* grown on agar plates

Pictures for *S. macrospora* strains or mycelium grown on agar plates were taken with the Digital Microscope VHX-500F (Keyence, Germany).

#### Fluorescence microscopy

CFW staining (Sigma-Aldrich, 18909) diluted 1:1 with 10% KOH was applied onto mycelium grown on BMM-covered slides to visualize cell walls and septa.

The 10 mM CMAC stock solution (CMAC solved in DMSO) was diluted 1:400 in H<sub>2</sub>O and 50-100  $\mu L$  were applied directly on *S. macrospora* mycelium. The samples were incubated for 30 min at 37°C. For staining of lipid rich membranes 50-100 $\mu L$  FM4-64 (1 $\mu g/mL$  H<sub>2</sub>O) was directly applied onto *S. macrospora* mycelium and fluorescence microscopy was performed after 10-20 min incubation at RT.

For the detection of the GFP, DsRED/TdTomato/FM4-64, DAPI/CMAC signals and calcofluor white (CFW) fluorescence chroma filter set 49002, 49005, 49000 and 89002 (exciter ET470/40x, ET545/30x, ET350/50x, ET430/24x/ET500/20x, emitter ET525/50m, ET620/60m, ET460/50m,

ET470/24m/ET535/30m and beamsplitter T495lpxr, T570lp, T400lp, 69008bs) were used, respectively.

### 1.6.11.2 DNA and protein sequence analysis

The Clone Manager 7, 7.04 software (Sci Ed Central, 1994-2002 Scientific & Educational Software) was used to generate plasmid sequences. For analysis of sequenced plasmids, sequence alignments were performed with the Nucleotide BLAST database (Altschul *et al.*, 1990) (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>). Also, DNA and protein sequences were obtained from the BLAST database. ExPASy GPSDB Gene/Protein Synonyms finder was used to identify orthologs of small coiled-coil proteins associated with the STRIPAK complex (Pillet *et al.*, 2005). ExPASy Compute pI/MW tool ([http://web.expasy.org/compute\\_pi/](http://web.expasy.org/compute_pi/)) was used to calculate the isoelectric point and the molecular weight of proteins. The program SMART 7.0 (Letunic *et al.*, 2015, Schultz *et al.*, 1998) (<http://smart.embl-heidelberg.de/>) was used to predict protein domains. The MPI Bioinformatics Toolkit COILS/PCOILS (Alva *et al.*, 2016) (<https://toolkit.tuebingen.mpg.de>) and the ExPASy COILS software (Lupas *et al.*, 1991) ([http://embnet.vital-it.ch/software/COILS\\_form.html](http://embnet.vital-it.ch/software/COILS_form.html)) were used to identify coiled-coil domains in proteins.

### 1.6.11.3 Phylogenetic analysis

Multiple sequence alignment of protein sequences was performed with Mafft version 7.182 (Katoh & Standley, 2013). Phylogenetic analysis was performed with the program PHYLIP, version 3.6 (<http://evolution.genetics.washington.edu/phylip.html>) (Felsenstein, 2005). The program PROTDIST was used to calculate the distance matrices, which were analysed with the NEIGHBOR program to generate phylogenetic trees. The bootstrap analysis was performed with 1000 iterations to rebuild and test the trees for statistical significance. Phylogenetic trees were generated with the program CONSENSE and displayed with the program TreeView 1.6.6. (Page, 1996). Adobe Illustrator CS2 12.0.0 was used to represent the phylogenetic trees.

### 1.6.11.4 LC-MS data analysis: MaxQuant/Perseus and Proteome Discoverer™

#### Analysis of LC/MS data with MaxQuant/Perseus

Proteins were identified with the MaxQuant 1.4.1.2. software (Cox & Mann, 2008) using the Andromeda algorithm. *S. macrospora* specific protein database (Nowrousian *et al.*, 2010) was used for database search. Default parameters were used and the digestion mode was trypsin/P. Maximum missed cleavage sites were 3, carbamidomethylation of cysteins was considered as fixed modification. The mass tolerance was 4.5 ppm for precursor ions and 0.5 Da for fragment ions. The decoy mode was revert with a false discovery rate of 0.01. Subsequent data processing and statistical analysis were performed with the Perseus 1.5.1.0 software (Cox & Mann, 2012, Tyanova *et al.*, 2016).

## Materials and Methods

**Table 10: Example of a workflow for LC/MS data analysis with MaxQuant/Perseus**

Step	Command	Description	Step	Command	Description	
1	Load raw Data files into MaxQuant Set Experiment	Data naming for example: 1GFP, 1HAPRO11eGFP 2GFP, 2HAPRO11eGFP 3GFP, 3HAPRO11eGFP	6	Processing Filter rows Filter rows based on valid values	Number of values 2 In at least one group: Group1 Values should be: Valid	
	Global Parameters: Insert Fasta file Requantify	Fasta file: Peptide library		7	Processing Imputation Replace missing values from normal distribution	Replace NaN, Width: 0.3 Down shift: 1.8 Mode: Separately for each columns
	Group specific parameters: Lable-free quantification	LFQ yes, default settings  Calculation done by MaxQuant		8	Analysis Clustering /PCA Hierarchical clustering Uncheck Column tree	heat map Adjust Colors Adjust data representation row/column height, width, Protein IDs
2	Generic upload Perseus Expression: LFQ intensity Numerical: PEP (Posterior error probability), Intensity, Razor + unique peptides, Sequence coverage, Peptides, unique Peptides Categorical: Only identified by site, Reverse, Contaminant, Text: Protein IDs, Majority protein IDs	proteinGroups.txt	9	Processing Tests Two-samples tests	Grouping: Group1, for example First Group: GFP Second Group: HAPRO11eGFP Test: t-test S0: 2 Side: both FDR:0.01 or 0.1 (False discovery rate)	
3	Processing Filter rows based on categorical column	Only identified by site Reverse Contaminant	10	Analysis Basic visualization scatter plot	x-axis: t-test Difference y-axis: -Log t-test <i>p</i> value Vulcano plot Selected labels t-test Significant Vulcano plot: Categories, click on t-test Significant Selected labels Protein IDs	
4	Processing Basic Transform	Log2(x)				
5	Processing Annotation rows Categorical annotation rows	Create Group1 Define which samples belong to the negative control and which are the samples of interest (for example GFP, HAPRO11eGFP)				

## Materials and Methods

For analysis with Perseus, label free quantification based on signal intensities was applied. Pull-down samples were analyzed from HAPRO11 (MS1-3) or HAPRO11eGFP (MS1-3), or FLAGSmMOB3 (MS1-3) or SmMOB3eGFP (MS1-3) or SCI1eGFP (MS1-3) (Table 8). To identify specifically enriched protein criteria were as follows, enriched in at least two LC/MS experiments compared to the corresponding negative controls. Proteins enriched in all three pull-downs were considered as highly confident.

The work flow used to analyze the LC/MS data with MaxQuant/Perseus in this work is presented in table 10. However, the workflow for analysis of LC/MS data is dependent on the needs of analysis and the obtained LC/MS data should be elaborated individually.

For the heat-map representation, intensity signals were set as follows, intensity very high (dark blue, 26), intensity high (blue, 24), intensity medium (light blue, 20-22), and intensity low (white, 18). A t-test was performed using Perseus and the results were represented by a volcano plot. Criteria for specifically enriched proteins were t-test difference  $< -3$  and  $p$ -value  $< 0.1$ .

### **Analysis of LC/MS data with the Proteome Discoverer™ software**

Proteins were also identified with the Proteome Discoverer™ 1.4 software (Thermo Scientific, version 1.4.0288) using SequestHT (Thermo Scientific) and Mascot search algorithms. The database searches were performed against a *S. macrospora* specific protein database (Nowrousian *et al.*, 2010) extended by the most common contaminants. For the maximum of misscleavage sites two residues were expected and the digestion mode was trypsin. Fixed modification was carbamidomethylation of cysteins. The mass tolerance was 10 ppm for precursor ions and 0.6 Da for fragment ions. The decoy mode was revert.

With the Proteome Discoverer™ LC/MS Data from each biological replicate of PRO11 (HAPRO11 and HAPRO11eGFP MS1, HAPRO11 and HAPRO11eGFP MS2 or HAPRO11 and HAPRO11eGFP MS3) or SmMOB3 (FLAGSmMOB3 and SmMOB3eGFP MS1, FLAGSmMOB3 and SmMOB3eGFP MS2 or FLAGSmMOB3 and SmMOB3eGFP MS3) or and corresponding negative controls (Table 8) were pooled and analyzed using spectral counts. Also, for SCI1eGFP each biological replicate (MS1-3) and the negative control eGFP were analyzed using spectral counts. The settings in the Proteome Discoverer™ were as follows, high peptide confidence and minimum 2 peptides with a false discovery rate less than 0.01. Criteria for specifically enriched proteins were, no peptides enriched in the negative control and at least 7 peptide counts in two of three LC/MS experiments. Comparing putative interaction partners found in PRO11 and simultaneously in SmMOB3 pull downs criteria were less stringent, no peptides enriched in the negative control and at least 5 peptide counts in two of three LC/MS experiments. The LC/MS Excel lists with the sum of spectral counts are supplemented on a digital video disk.

### **1.6.12 Measures of safety**

Genetic engineering experiments of security level 1 have been conducted according to the guide lines of the genetic engineering law (GenTG) stated on 16.12.1993 (recently altered by Art. 12 G v. 29.7.2009 I 2542).

## 2. Results

### 2.1 Pull-down experiments and LC/MS with the STRIPAK proteins PRO11 and SmMOB3

The STRIPAK complex of *S. macrospora* consists of the ortholog of striatin PRO11, the kinase activator SmMOB3, the STRIP1/2 ortholog PRO22, the SLMAP ortholog PRO45, the phosphatase scaffolding subunit SmPP2AA and the catalytic phosphatase subunit SmPP2Ac1 (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015). PRO11 is thought to act as scaffolding protein for the association of the STRIPAK components and interacts with SmMOB3 (Bloemendal *et al.*, 2012). Thus, by means of liquid chromatography-mass spectrometry (LC/MS) proteins that associate with PRO11 and SmMOB3 were identified in this study.

#### 2.1.1 LC/MS data analysis with MaxQuant/Perseus identified a putative interaction partner of PRO11 with high confidence

To identify putative interaction partners of HAPRO11, total protein content from  $\Delta$ pro11::hapro11 (Bloemendal *et al.*, 2012) and wt::ha (negative control) mycelium was enriched by HA-Trap, resolved in SDS-PAGE and digested with trypsin. The eluted peptide samples were analyzed by LC/MS (Hellman *et al.*, 1995, Speicher *et al.*, 2000). The data were analyzed in a semiquantitative method using MaxQuant/Perseus (Cox & Mann, 2008, Cox & Mann, 2012, Tyanova *et al.*, 2016) and label-free quantification (LFQ) based on signal intensities (section 1.6.11.4). Proteins enriched in at least two LC/MS experiments but not in the corresponding negative control were considered as putative interaction partners. The overall number of proteins identified in the respective pull-downs is given in table 11. Candidates enriched in all three LC/MS experiments were considered as high confidence interaction partners. MaxQuant/Perseus data analysis was visualized in a heat map and a volcano plot (Figure 8).

In the heat map high signal intensities are indicated by dark colors and low signal intensities are indicated by light colors. For simplicity only the signal intensities for the first 20 detected proteins are presented in figure 8A. Peptides of the HAPRO11 bait protein were identified with high signal intensity in all three LC/MS replicates colored in dark blue. Furthermore, peptides of the known PRO11 (SMAC\_08794) interaction partner PRO22 (SMAC\_02580) and a protein with the locus tag

## Results

SMAC\_05559 were copurified. The new protein was named STRIPAK complex interactor 1 (SCI1). SCI1 was highly enriched by HAPRO11 in the first and second pull down and moderately enriched in the third pull-down experiment. PRO22 was also highly enriched by HAPRO11 in the first and second pull down but only slightly enriched in the third pull-down. PRO11, PRO22 and SCI1, were not enriched in the negative control (Figure 8 A).

**Figure 8: LC/MS data from HA-Trap with HAPRO11 as bait represented in a heat map and a volcano plot**  
In the heat map and the volcano plot the results of the HA-Trap and LC/MS are represented. **A:** The heat map shows the results of the HAPRO11-LC/MS1, 2 and 3 with the corresponding HA negative controls 1, 2 and 3. Signal intensities correlate with the abundance of the peptides detected. White represents low signal intensities and dark blue indicates high signal intensities. In total, 1229, 1103 and 1529 proteins were identified with MaxQuant/Perseus but for simplicity only the results for the first 20 identified proteins are represented in the heat map. Signal intensities for the bait protein with the locus tag SMAC\_08794 (PRO11) were high in all LC/MS experiments. PRO22 (SMAC\_02580) was highly enriched in LC/MS1 and 2 and SCI1 (SMAC\_05559) was enriched in all three LC/MS experiments. **B:** The volcano plot represents the results of a statistical 2 sample t-test. Putative PRO11 interaction partners have a  $p$ -value  $< 0.1$  and a t-test difference value of  $< -3$ .

A statistical 2-sample t-test was performed using signal intensities, and the results are presented as volcano plot to discriminate significant candidates identified in the HAPRO11 pull downs from unspecific background. Identified proteins with a t-test difference  $> 0$  represent the identified proteins detected in the negative control and  $< 0$  represent proteins enriched with HAPRO11 (Figure 8B). Candidates classified as unspecific background have a t-test difference  $> -3$ . Candidates having a  $p$  value  $< 0.1$  and a t-test difference  $< -3$  were classified as significant and thus putative

## Results

PRO11 interaction partners. Here, PRO11 groups together with its known interaction partner PRO22 and with the novel protein SCI1 (Figure 8B).

Also, total protein content was isolated from *pro11::hapro11egfp* (Herzog and Pöggeler unpublished) and from *wt::egfp* (Voigt & Pöggeler, 2013). GFP-Trap and LC/MS was performed and the data was evaluated to the same criteria as described before. Neither PRO22 nor SCI1 could be enriched with HAPRO11eGFP expressed in the *pro11* mutant. However, SmMOB3, a known interaction partner of PRO11, was identified as high confidence interaction partner of the HAPRO11eGFP fusion protein (Figure S 1 A/B). The results also apply vice versa, SmMOB3 was not enriched in the HAPRO11 pull-down (Figure S 1 A/B, Figure 8).

Also the total protein contents were isolated from the *fus::flagSmmob3* and the  $\Delta$ *Smmob3\_gpd-MOB3:GFP* strain and the corresponding negative controls *wt::flag/wt::egfp*, followed by FLAG-Trap or GFP-Trap, respectively coupled to LC/MS.

However, only in the SmMOB3eGFP pull-downs PRO11 was identified as high confidence interaction partner and no further interaction partners matching the criteria were identified in FLAGSmMOB3 and SmMOB3eGFP pull-downs (Figure S 1 C/D and E/F). The overall number of different proteins identified with MaxQuant/Perseus in the respective pull-downs is given in table 11. The complete heat maps for PRO11 and SmMOB3 pull-downs are presented in figure S 2 and the position of the protein used for the respective pull-down is indicated by an arrow.

**Table 11: Sum of proteins identified with MaxQuant/Perseus from PRO11 and SmMOB3 pull-downs**

Pull-down	LC/MS1	LC/MS2	LC/MS3	LC/MS1, 2 and 3
<b>HAPRO11</b>	1229	1103	1529	1822
<b>HAPRO11eGFP</b>	714	744	1060	1293
<b>FALGSmMOB3</b>	1461	1644	1563	2018
<b>SmMOB3eGFP</b>	695	875	986	1180

The overall number of different proteins (specific and unspecific) identified from the indicated pull-downs with the MaxQuant/Perseus software is presented. The number of all different proteins identified altogether in LC/MS1, 2 and 3 is also given.

### 2.1.2 LC/MS Data analysis with the Proteome Discoverer™ identified several putative interaction partners of PRO11 and SmMOB3

The Proteome Discoverer™ (Thermo Scientific) was used to evaluate the data combined from HAPRO11 (LC/MS1-3) and HAPRO11eGFP (LC/MS1-3) (PRO11 pull-down) or FLAGSmMOB3 (LC/MS1-3) and SmMOB3eGFP (LC/MS1-3) (SmMOB3 pull-down) using the sum of spectral counts. The overall number of proteins identified in the respective pull-downs is given in table 12.

**Table 12: Number of proteins identified with the Proteome Discoverer™ from PRO11 and SmMOB3 pull-downs**

Pull-down	LC/MS1	LC/MS2	LC/MS3	LC/MS1-3
<b>HAPRO11</b>	901	684	998	1205
<b>HAPRO11eGFP</b>	545	463	717	820
<b>FLAGSmMOB3</b>	943	991	1038	1302
<b>SmMOB3eGFP</b>	425	597	586	748

The overall number of different proteins (specific and unspecific) identified from the indicated pull-downs with the Proteome Discoverer™ software is presented.

The criteria for analysis with the Proteome Discoverer™ were: high peptide confidence and a minimum of two peptides with a false discovery rate less than 0.01. For potential interaction partners the criteria were: no peptides enriched in the negative control and at least 7 peptide counts. Tagged PRO11 and SmMOB3 were enriched in the respective pull-down/LC/MS experiments in large numbers of spectral counts (Table S 1, Table S 2).

In two replicates of PRO11 pull-downs, SmMOB3 (SMAC\_00877) and PRO22 (SMAC\_02580) were identified with minimal 7 spectral counts. Remarkably, spectral counts for SmMOB3 were high when spectral counts for PRO22 were low and vice versa (Table S 1). The protein SCI1 with the locus tag SMAC\_05559 was identified in all three biological replicates of the PRO11 pull-downs in large numbers of spectral counts (Table S 1). Further, 25 possible interaction partners were identified in PRO11 pull-downs, among them 4 proteins involved in transport: a kinesin group protein (SMAC\_04212), an actin-2 protein (SMAC\_07827), a vacuolar sorting protein (SMAC\_04470) and a Sar1-like protein (SMAC\_04918). Furthermore, three kinases, two STKs (SMAC\_04710 and SMAC\_05353) and one STE20-like kinase (SMAC\_07811), a nucleoporin (SMAC\_02409) and a small GTPase of the Ras family (SMAC\_07014) were identified (Table S 1).

## Results

In SmMOB3 pull-downs PRO11 was identified in high numbers of spectral counts but no further STRIPAK member that matched the criteria. On the other hand, four unknown protein were identified. Two of them, a putative myosin-5 protein (SMAC\_05008) and the AP-2 complex subunit alpha (SMAC\_09495) are related to transport (Table S 2).

To get an idea which peptides are found in all PRO11 and SmMOB3 pull-downs the criteria were set as follows: high peptide confidence, minimal 2 peptides per protein, not enriched in the negative control and at least 5 peptide counts in at least two biological PRO11 and SmMOB3 replicates, respectively. PRO11, PRO22 and SCI1 were detected in almost all experiments but also the putative myosin-5 protein (SMAC\_05008), a nucleoporin (SMAC\_02409) and the serine/threonine-protein phosphatase 1 (PP1) were detected (Table S 3).

### **2.2 Small coiled-coil proteins that associate with the STRIPAK complex in fungi and animals are conserved through their domain structure**

The protein SCI1 (SMAC\_05559) was enriched in HA-Trap experiments using HAPRO11 as bait combined with LC/MS. The ORF *SMAC\_05559* encodes a protein of 298 amino acids (AA) with a predicted molecular weight (Mw) of 33 kDa and an isoelectric point (pI) of 5.07. Only coiled-coil (CC) regions were identified with the SMART database (Letunic *et al.*, 2015, Schultz *et al.*, 1998) and in total four CC domains were predicted for the SCI1 protein with the MPI Bioinformatics Toolkit COILS/PCOILS (Alva *et al.*, 2016) and the ExpASY COILS (Lupas *et al.*, 1991) program.

The CC domains in SCI1 were predicted in the following AA positions: 22-55, 68-113, 138-184 and 235-267. In mammals and yeasts, small proteins associating with the STRIPAK complex contain one or more CC domains (Figure 9). In *S. cerevisiae*, Far3 (204 AA) and Far7 (221 AA) represent two CC domain containing protein associated with the Far complex. Far3 was predicted to have two CC domains and Far7 only one (Lai *et al.*, 2011). In *S. pombe*, Csc4 (166 AA) has only one CC region and was found in the SIN-inhibitory PP2A (SIP) complex (Singh *et al.*, 2011).

The STRIPAK complex in *H. sapiens* can associate with SIKE (207 AA) or FGFR1OP2 (253 AA), which are closely related (Goudreault *et al.*, 2009). For SIKE, two CC domains were predicted but a third CC region between AA 2 and 46 might also exist (Huang *et al.*, 2005a). Whereas, for FGFR1OP2 four CC were predicted (Lin *et al.*, 2010). In *D. melanogaster*, FGOP2 (315 AA) associates with the

## Results

dSTRIPAK but is not extensively studied in fruit flies (Ribeiro *et al.*, 2010). For FGOP2 three CC domains were predicted with COILS/PCOILS and COILS (Figure 9).

**Figure 9: Domain structure of small coiled-coil proteins associated with the STRIPAK in fungi and animals**  
Schematic representation of small CC proteins associating with the orthologous STRIPAK complexes of *S. macrospora*, *S. cerevisiae*, *S. pombe*, *H. sapiens* and *D. melanogaster* and their predicted domain structure. All proteins contain one or more cc regions distributed over the protein. Numbers represent the length of the corresponding protein in amino acids (AA). CC: Coiled-coil domain (green). SCI1: STRIPAK complex interactor 1 (XP\_003349276), Far3 (AAB39035)/7(P43592): Factor arrest 3/7, Csc4 (O14043): Component of SIP complex, SIKE (NP\_079349): Suppressor of IKK $\epsilon$ , FGFR1OP2 (NP\_001165358)/FGOP2 (NP\_609084): Fibroblast growth factor receptor 1 oncogene partner 2.

### 2.3 Small CC proteins associated with the STRIPAK complex are conserved within phyla belonging to distant clades

Small proteins containing CC domains associate with the STRIPAK in different organisms (Hwang & Pallas, 2014). However, it is not possible to determine orthologs by BLAST searches due to the low conservation of the AA sequences between animals, yeasts and filamentous fungi. Therefore, SIKE and FGFR1OP2 orthologs in animals were identified with the GPSDB Gene/Protein Synonyms finder (Pillet *et al.*, 2005) and BLAST (Altschul *et al.*, 1990) using human SIKE and FGFR1OP2. In filamentous fungi, BLAST search with *S. macrospora* SCI1 identified putative fungal SCI orthologs. Full length amino-acid sequences of SIKE/FGFR1OP2, Far3/7, Csc4 and SCI proteins were aligned with MAFFT (Kato & Standley, 2013) and neighbor joining was performed with the program NEIGHBOR of the program package PHYLIP (Felsenstein, 2005). Despite being barely conserved by AA sequence, small STRIPAK-associated proteins containing CC domains are conserved within phyla belonging to distant clades presented in the unrooted neighbor-joining tree (Figure 10).

## Results

**Figure 10: Phylogenetic tree of small CC proteins associated with the STRIPAK**

Phylogenetic tree of STRIPAK-associated proteins containing CC domains generated with the neighbor-joining method and shown in a distance matrix. Orthologs were identified with BLAST search using amino acid sequences of human SIKE and FGFR1OP2 and *S. macrospora* SCI1. The multiple sequence alignment was performed with MAFFT version 7.182 (Kato & Standley, 2013) using the amino acid sequences: Sm SCI1, *S. macrospora* (XP\_003349276.1); Nc SCI, *N. crassa* (XP\_960970.1); Ct SCI, *Chaetomium thermophilum* (XP\_006696634.1); Vd SCI, *Verticillium dahliae* (EGY17808.1); Pa SCI, *Podospora anserina* (XP\_001912083.1); Mo SCI, *Magnaporthe oryzae* (XP\_003715088.1); Af SCI, *Aspergillus fumigatus* (XP\_752657.2); An SCI, *A. nidulans* (XP\_658614.1); Sc, *S. cerevisiae* Far3 (AAB39035) and Far7 (P43592); Sc Csc4, *S. pombe* Csc4 (O14043); Dm FGOP2, *D. melanogaster* FGOP2 (NP\_609084); Hs SIKE, *H. sapiens* SIKE (NP\_079349.2); Mm SIKE, *M. musculus* SIKE (NP\_079955.1); Gg SIKE, *Gallus gallus domesticus* SIKE (NP\_001006324.2); XI SIKE, *Xenopus laevis* SIKE (NP\_001085744.1); Dr SIKE, *Danio rerio* SIKE (XP\_696578.2); Hs 1FGFR1OP2, *H. sapiens* isoform 1 FGFR1OP2 (NP\_056448.1); Hs 2FGFR1OP2, *H. sapiens* isoform 2 FGFR1OP2 (NP\_001165358.1); Mm 1FGFR1OP2, *M. musculus* isoform 1 FGFR1OP2 (NP\_080494.1); Mm\_2FGFR1OP2, *M. musculus* isoform 2 FGFR1OP2 (XP\_006536173.1); Gg FGFR1OP2, *G. domesticus* FGFR1OP2 (NP\_001007856.1); XI FGFR1OP2, *X. laevis* FGFR1OP2 (NP\_001079401.1); Dr FGFR1OP2, *D. rerio* FGFR1OP2 (NP\_956249.1). For the calculation of the phylogenetic tree programs of PHYLIP 3.63 were used (Felsenstein, 2005). The bootstrap values <70% (rounded to whole numbers) based on 1000 replications are indicated at the nodes. Distant clades: SCI-like proteins are found in filamentous fungi (green), Far3/7, Csc4 are found in yeasts (yellow), SIKE-like proteins (blue) and FGFR1OP2-like proteins (purple) are found in the phylum Chordata. The FGOP2 protein, of *D. melanogaster* grouped out because the AA sequence was clearly different compared to the other sequences.

## Results

### 2.4 SCI1 proteins are conserved in filamentous ascomycetes

The phylogenetic tree of STRIPAK-associated proteins containing CC domains showed that *S. macrospora* SCI1 and SCI orthologs from *N. crassa*, *Podospora anserina*, *Chaetomium thermophilum*, *Verticillium dahliae*, *Magnaporthe oryzae*, *A. nidulans* and *Aspergillus fumigatus* cluster together. To shed light on this, a multiple-sequence alignment of 8 fungal SCI proteins using MAFFT was performed. With the help of MAFFT, the most conserved region among fungal SCI orthologs was identified (Figure 11).

The phylogenetic analysis using neighbor joining showed that SCI1 orthologs from Sordariomycetes or Eurotiomycetes cluster together (Figure S 4 A). Based on the AA alignment, the highest sequence identity was observed between SCI1 of *S. macrospora* and the SCI ortholog in *N. crassa* (93%). Lower sequence identity was observed between *S. macrospora* and *M. oryzae* (56%) and the lowest sequence identity was observed between *S. macrospora* and *A. fumigatus* (20%) or *A. nidulans* (18%) (Figure S 4 B).

**Figure 11: Multiple-sequence alignment of SCI1 proteins in filamentous ascomycetes**

The multiple sequence alignment was performed with MAFFT (Kato & Standley, 2013) using the amino acid sequences: Sm, *S. macrospora* (XP\_003349276.1); Nc, *N. crassa* (XP\_960970.1); Ct, *C. thermophilum* (XP\_006696634.1); Vd, *V. dahliae* (EGY17808.1); Pa, *P. anserina* (XP\_001912083.1); Mo, *M. oryzae* (XP\_003715088.1); Af, *A. fumigatus* (XP\_752657.2); An, *A. nidulans* (XP\_658614.1). The alignment is represented with GeneDoc (Nicholas & Nicholas, 1997). The overall protein length in amino acids (AA) is presented in brackets and the amino-acid region used for the alignment is indicated at the right hand side at the end of the alignment. Amino acids conserved in all sequences are shaded in black, amino acids conserved in 6 of 8 sequences are shaded in dark gray and amino acids conserved in 5 of 8 sequences are shaded in light gray. Predicted coiled-coil regions are shaded in green.

However, also highly conserved regions between Sordariomycetes and Eurotiomycetes (*A. nidulans* and *A. fumigatus*) exist in the N-terminal regions and in the central regions of SCI proteins. To investigate whether CC domains are also conserved in the 8 fungal SCI proteins COILS/PCOIL and COILS analysis was performed and the predicted CC domains are presented in green in figure 11. The first CC domain was predicted in *S. macrospora*, *N. crassa*, *C. thermophilum* and *V. dahliae*, the second CC was predicted for all 8 fungal SCI sequences investigated and the third CC was predicted in SCI proteins of Sordariomycetes.

## 2.5 The *sci1* gene is upregulated during sexual development

*S. macrospora* propagates sexually by meiotic ascospores, which are generated within fruiting bodies. Sexual development starts at day 2-3 when ascogonia, are formed developing into protoperithecia at day 3-4 and into mature perithecia filled with ascospores at day 6-7 (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014). One complex regulating hyphal fusion and sexual development is the STRIPAK complex in *S. macrospora* (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Kück *et al.*, 2016, Nordziede *et al.*, 2015, Pöggeler & Kück, 2004). Expression of the STRIPAK genes *Smmob3* and *pro11* was previously shown to be upregulated during sexual development (Bernhards & Pöggeler, 2011). Transcript levels of *pro45* in vegetative and sexual mycelium and in protoperithecia from day 3-5 had a low abundance in whole transcriptome shotgun sequencing (RNA-seq) analysis (Teichert *et al.*, 2012). In contrast, expression of *pro22* increases in sexual development of *S. macrospora* up to 4-fold after day 4 (Bloemendal *et al.*, 2010). Therefore, the expression level of *sci1* in *S. macrospora* was investigated with quantitative reverse-transcription PCR (qRT-PCR).

The open reading frame (ORF) of the *sci1* gene (*SMAC\_05559*) consists of 976 bp and contains one putative intron of 79 bp at the position 242-320. Comparison of genomic and cDNA sequences confirmed the position and the intron size in the *sci1* gene. The genomic sequence of *sci1* and the translated protein sequence are presented in figure S 5. In the qRT-PCR transcript levels of *sci1* during vegetative growth were compared to expression levels during sexual growth, after 3, 4, 5, 6 and 7 days. The *sci1* gene was significantly upregulated at day 3 and 7 but significantly downregulated at day 4. The highest *sci1* transcript level was recorded after day 3, which is the

## Results

developmental stage when ascogonia are formed (Figure 12). The fragments amplified in qRT-PCR with the help of the primer pair RTsci1f/RTsci1r are presented in figure S 6.

**Figure 12: Quantitative reverse-transcription PCR analysis of *sci1***

RNA was isolated from wt grown in liquid shaking cultures (vegetative growth) and from floating cultures (sexual growth) at day 3-7. qRT-PCR was performed with the primer pair RTsci1f/RTsci1r using cDNA derived from the isolated RNA. Expression of the *sci1* gene was compared at vegetative and sexual growth (log<sub>10</sub> ratio sexual versus vegetative growth) conditions at day 3-7. Mean expression values are derived from 2 independent biological samples measured in triplicates. Standard deviations are given by error bars and stars represent significant results calculated with “REST” (Pfaffl *et al.*, 2002) *p*-values: 3d, 4d and 7d < 0.001, 5d: 0.509, 6d: 0.505.

### 2.6 Successful generation of a *sci1* deletion strain

Deletion of STRIPAK components of *S. macrospora* result in defects in hyphal fusion and sterile strains unable to reproduce sexually (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Kück *et al.*, 2016, Nordziske *et al.*, 2015, Pöggeler & Kück, 2004). Since SCI1 is a putative interaction partner of PRO11 it should be analyzed if a deletion of *sci1* results in a similar phenotype as described for *S. macrospora* strains lacking other STRIPAK components.

For this purpose, a *sci1* deletion strain was generated by homologous recombination in the *S. macrospora*  $\Delta ku70$  strain replacing the *sci1* ORF with a *hph* resistance cassette. The  $\Delta ku70$  strain was used because it is reduced in non-homologous end-joining increasing homologous integration efficiency (Pöggeler & Kück, 2006). The obtained heterokaryotic mutant strains were crossed to the color spore mutant *fus1-1* to reintroduce the *ku70* gene and to generate homokaryotic  $\Delta sci1_{hyg}$  strains. The *fus1-1* strain resembles the wild type but produces brown spores instead of black spores because of a defect in melanin synthesis (Nowrousian *et al.*, 2012). Black and brown single

## Results

spore isolates (*ssi*) were selected and deletion of the *sci1* gene was confirmed by PCR and Southern blot (Figure 13).

**Figure 13: PCR and Southern blot analysis of wt,  $\Delta ku70$ ,  $\Delta sci1_{hyg}$  and  $fus\Delta sci1_{hyg}$**

**A:** Schematic representation of the *sci1* ORF with one intron (green box), 5' flanking region (blue) and 3' flanking region (purple). After homologous recombination the *hph* cassette replaced the whole *sci1* ORF. Primer combinations, the corresponding fragment sizes, the probe size and hybridization region are indicated. **B:** Verification of homologous integration of the *hph* cassette into the *sci1* locus using PCR. Genomic DNA was isolated from wt,  $\Delta ku70$ ,  $\Delta sci1_{hyg}$  and  $fus\Delta sci1_{hyg}$  and tested with given primer combinations. The marker GeneRuler™ 1 kb DNA Ladder (Fisher Scientific) was used for gel-electrophoresis and for the Southern blot. The fragments are given in bp for the identification of the amplicons or in kb for the Southern blot. The primer pair hph1/*sci1\_vr* generates a second fragment of about 600 bp for all tested gDNAs, which most likely is caused by unspecific binding of the primers. **C:** Confirmation of  $\Delta sci1_{hyg}$  and  $fus\Delta sci1_{hyg}$  was done by Southern blot. The isolated gDNA was hydrolyzed with *Sacl*, the probe and the marker were labeled with alkaline phosphatase, and signals were detected on X-ray films. Signals detected correspond to a fragment size of 2.8 kb for wt and  $\Delta ku70$  locus and 3.3 kb for  $\Delta sci1_{hyg}$  and  $fus\Delta sci1_{hyg}$  locus.

## 2.7 Macroscopic and microscopic analysis of the $\Delta sci1_{hyg}$ strain

### 2.7.1 The *sci1* deletion strain is sterile, produces less protoperithecia than the wt and is devoid of hyphal fusion

For analyzing the impact of *sci1* on sexual development, as shown before for *pro11*, *pro22*, *pro45*, *Smpp2ac1* and *Smmob3*,  $\Delta sci1_{hyg}$  was investigated macroscopically and microscopically (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Kück *et al.*, 2016, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004).

The wt as well as the *sci1* deletion strain were grown on BMM medium and the formation of sexual structures was monitored. The wt, produces first sexual structures at day 2-3, protoperithecia at day 3-4 and mature perithecia filled with ascospores at day 6-7 (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014). In contrast, the  $\Delta sci1_{hyg}$  strain generated ascogonia at day 3 but was unable to produce pigmented protoperithecia and perithecia (Figure 14).

Even after prolonged incubation for 21 days or longer at 27°C, no pigmented protoperithecia and perithecia could be detected. The  $\Delta sci1_{hyg}$  produced dense areal hyphae, which led to a cotton-like appearance after prolonged incubation. However, the sterile  $\Delta sci1_{hyg}$  phenotype could be complemented with a *sci1* full-length construct fused to the *egfp* sequence, under the control of the endogenous *sci1* promoter. Fertility was restored in the  $\Delta sci1_{hyg}::5'sci1egfp$  strain which expresses a C-terminally eGFP tagged SCI1 protein ectopically. Similar to the wt the  $\Delta sci1_{hyg}::5'sci1egfp$  strain produces ascogonia at day 2-3, protoperithecia at day 3-4 and mature perithecia at day 6-7 (Figure 14 A).

Not only the development of the  $\Delta sci1_{hyg}$  strain is arrested at the stage of unpigmented protoperithecia but also the number of protoperithecia appeared to be reduced. Therefore, protoperithecia with a size of 40-200  $\mu m$  of wt,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$  grown on BMM-covered slides were counted per  $cm^2$ . The experiment was performed in five independent replicates (n=5). The wt produced almost 200 protoperithecia/ $cm^2$  while the number of protoperithecia in the *sci1* deletion strain was reduced by 78.5% (43 protoperithecia/ $cm^2$ ) compared to the wt strain. The number of protoperithecia in the complementation strain  $\Delta sci1_{hyg}::5'sci1egfp$  was reduced by 50% (100 protoperithecia/ $cm^2$ ) compared to the wt (Figure 14 B).

## Results

**Figure 14: Sexual structures in the wt,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$**

**A:** Microscopic investigation of the wt,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$  grown on BMM medium at day 2, 3, 4 and 6. The wt and the  $\Delta sci1_{hyg}::5'sci1egfp$  strain develop ascogonia, unpigmented and pigmented protoperithecia and perithecia but the  $\Delta sci1_{hyg}$  develops only ascogonia and unpigmented protoperithecia. For the wt and the  $\Delta sci1_{hyg}::5'sci1egfp$  also a zoomed single perithecium is presented in the upper right corner of the pictures. Pig.: pigmented, d: day **B:** Wt,  $\Delta sci1_{hyg}$  and the  $\Delta sci1_{hyg}::5'sci1egfp$  were grown on BMM and protoperithecia with a size of 40-200 μm in an area of 1 cm<sup>2</sup> were counted in five independent experiments (n=5). The wt produces almost 200 protoperithecia/cm<sup>2</sup> whereas the  $\Delta sci1$  only produces 43 protoperithecia/cm<sup>2</sup>. In the partially complemented strain  $\Delta sci1::5'sci1egfp$  100 protoperithecia/cm<sup>2</sup> were counted. Error bars represent the standard deviation. Significant results calculated with Student's t-test (*p*-value < 0.0001) are indicated with an asterisk. **C:** The indicated strains were grown on minimal medium containing soluble starch (MMS) (Rech *et al.*, 2007) covered glass slides for 2 days and hyphal fusion was detected in wt and  $\Delta sci1_{hyg}::5'sci1egfp$  but not in  $\Delta sci1_{hyg}$ . Hyphal fusion events are marked with arrows and hyphae making contact without fusion are marked with asterisks. **D:** The strain  $\Delta sci1_{hyg}$  was crossed against the sterile strains  $\Delta Smmob3/fus1$ ,  $\Delta pro11/fus1$  and the fertile strain *fus1-1*. Crosses shown were incubated for 14 days. Perithecia with recombinant asci were only detected in  $\Delta sci1_{hyg} \times fus1-1$  crosses. Scale bars as indicated.

## Results

Although, the *5'sci1egfp* construct was able to complement the sterile  $\Delta sci1_{hyg}$  phenotype it only partially complemented the reduced protoperithecia phenotype, an effect which might be caused by ectopically integration of the *5'sci1egfp* construct.

*S. macrospora* strains without STRIPAK genes *pro11*, *Smmob3*, *pro22*, *pro45*, and *Smpp2ac1* are devoid of hyphal fusion (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordziede *et al.*, 2015, Pöggeler & Kück, 2004, Kück *et al.*, 2016, Beier *et al.*, 2016). Therefore, it was of interest if this is also true for  $\Delta sci1_{hyg}$ .

The strains  $\Delta sci1_{hyg}$ , wt and  $\Delta sci1_{hyg}::5'sci1egfp$  were grown for two days on minimal medium containing soluble starch (MMS) and were investigated microscopically (Rech *et al.*, 2007). In contrast to the wt and the complemented strain,  $\Delta sci1_{hyg}$  was not capable to form hyphal fusion "bridges". Hyphae of  $\Delta sci1_{hyg}$  made contact with other hyphae but hyphal tip extension did not stop (Figure 14 C). To analyze if the hyphal fusion defect of the  $\Delta sci1_{hyg}$  strain can be complemented by crossing the sterile and hyphal fusion defective strains in the *fus1-1* background,  $\Delta pro11/fus1$ ,  $\Delta Smmob3/fus1$  were crossed against  $\Delta sci1_{hyg}$  (Nowrousian *et al.*, 2012). These crosses failed to generate perithecia even after prolonged incubation of 14 days in the contact zone indicating that all three strains  $\Delta sci1_{hyg}$ ,  $\Delta pro11/fus1$  and  $\Delta Smmob3/fus1$  are hyphal fusion defective.

However, crossing of  $\Delta sci1_{hyg}$  against the brown-color spore mutant *fus1-1* resulted in hybrid perithecia in the contact zone containing asci with four black and four brown ascospores (Figure 14 D). Thus, the genetic defect of the  $\Delta sci1_{hyg}$  strain can be complemented by a strain, which is capable of hyphal fusion indicating that one wt crossing partner is sufficient to mediate hyphal fusion.

### 2.7.2 The vegetative growth rate of the $\Delta sci1_{hyg}$ and the $\Delta sci1_{hyg}\Delta pro11$ strain is reduced

As the  $\Delta sci1_{hyg}$  strain appeared to grow very slow compared to the wt, the vegetative growth rate of  $\Delta sci1_{hyg}$ , wt and the  $\Delta sci1_{hyg}::5'sci1egfp$  was investigated in race tubes filled with SWG. The growth rate of the  $\Delta sci1_{hyg}$  strain was reduced by 91.5% (3 mm/day) compared to wt (35 mm/day), indicating an involvement of SCI1 in vegetative growth. The vegetative growth rate of the complemented strain was reduced by 24% (28 mm/day) (Figure 15 A).

As SCI1 and PRO11 might interact in the STRIPAK complex of *S. macrospora* it was of interest to determine the effect of a simultaneous deletion of *sci1* and *pro11*. Therefore, a double deletion

## Results

strain ( $\Delta sci1_{hyg}\Delta pro11$ ) was generated and the vegetative growth rate was investigated. To generate  $\Delta sci1_{hyg}\Delta pro11$ ,  $\Delta pro11$  was crossed with a fertile strain  $fus\Delta sci1_{hyg}::5'sci1egfp$  capable to fuse to  $\Delta pro11$  and hygromycin resistant, nourseothricin sensitive strains were selected to eliminate the ectopically integrated  $5'sci1egfp$  construct. The strains were sterile and deletions of  $pro11$  and  $sci1$  were verified by PCR (Figure S 7).

**Figure 15: Vegetative growth rates of the wt,  $\Delta sci1_{hyg}$ ,  $\Delta sci1_{hyg}::5'sci1egfp$ ,  $\Delta sci1_{hyg}\Delta pro11$  and  $\Delta sci1_{hyg}\Delta pro11::sci1Dsred+hapro11egfp$**

**A:** Wt,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$  and **B:** wt,  $\Delta sci1_{hyg}\Delta pro11$  and  $\Delta sci1_{hyg}\Delta pro11::sci1Dsred+hapro11egfp$  were grown in race tubes filled with SWG for 6 days and the vegetative growth rate was monitored. The vegetative growth rate was calculated in mm/d and the wt growth rate was defined as 100 %. The standard deviations are represented as error bars. The vegetative growth rate was evaluated from three independent biological replicates performed in triplicates (n=3). Significant results calculated with Student's t-test ( $p$ -value **A:**  $\Delta sci1_{hyg} < 0.0001$  and **B:**  $\Delta sci1_{hyg}\Delta pro11 < 0.0001$ ) are indicated with an asterisk.

The  $\Delta sci1_{hyg}\Delta pro11$  strain showed a reduced growth rate of 91.8% (3 mm/day) compared to wt (36 mm/day) which is similar to the reduced growth rate of 91.5% of  $\Delta sci1_{hyg}$  (Figure 15 B). A  $sci1Dsred$  construct and a  $hapro11egfp$  construct, both under the control of the *Pccg1* promoter complemented the sterile phenotype of  $\Delta sci1_{hyg}\Delta pro11$  strain.

Similar as described for  $\Delta sci1_{hyg}::5'sci1egfp$ , ectopic integration of the fusion genes  $hapro11egfp$  and  $sci1Dsred$  into  $\Delta sci1_{hyg}\Delta pro11$  does not fully complement the vegetative growth phenotype of  $\Delta sci1_{hyg}\Delta pro11$  (Figure 15). However, the constructs  $5'sci1egfp$ ,  $hapro11egfp$  and  $sci1Dsred$  were functional because the growth phenotypes of the deletion mutants were partially restored and perithecia were detected. Therefore,  $\Delta sci1_{hyg}$  and the  $\Delta sci1_{hyg}\Delta pro11$  strain have a comparable reduced vegetative growth phenotype. Comparable, to the findings in this thesis, reduced vegetative growth phenotypes were also reported for deletion of other STRIPAK genes *Smmob3*,

*pro11*, *pro22*, *pro45* and *Smpp2Ac1* (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004).

### 2.7.3 Growth of the $\Delta sci1_{hyg}$ strain is slightly increased in presence of $H_2O_2$ and $CaCl_2$ or under nitrogen-limiting conditions

To further characterize the *sci1* deletion strain growth in comparison to the wt, *pro11*,  $\Delta pro11$ , and  $\Delta sci1_{hyg}::5'sci1egfp$  strains was investigated under several stress inducing conditions. All 5 strains were grown for 7 days on SWG stress media supplemented with 0.01%  $H_2O_2$  (oxidative stress), 0.1 M NaCl, 0.4 M Sorbitol (osmotic stress), 0.003% SDS (cell wall stress), and SWG without  $KNO_3$  (nitrogen starvation).  $Ca^{2+}$  is involved in hyphal tip growth (Silverman-Gavrila & Lew, 2001, Takeshita *et al.*, 2017) and *Smpp2Ac1* deletion strains are sensitive to high glucose levels (Beier *et al.*, 2016, Son & Osmani, 2009). Therefore, growth was also tested on SWG containing 0.6 M Glucose (osmotic stress) and SWG supplemented with 0.01 M  $CaCl_2$  (osmotic stress/high  $Ca^{2+}$  levels) (Figure S 8). Since, the STRIPAK components *SmPP2Ac1* and *PRO22* were implicated in the cell wall integrity (CWI) pathway, growth of wt, *pro11*,  $\Delta pro11$ ,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{hyg}::5'sci1egfp$  was also tested on SWG medium containing 100  $\mu g/mL$  calcofluor white (CFW). The color of the SWG medium supplemented with CFW was blue but the wt and the  $\Delta sci1_{hyg}::5'sci1egfp$  strain fully covered the medium (Figure S 8).

Some stresses did or did not reduce growth of the wt. Almost, all stresses tested reduced growth of the *pro11*,  $\Delta pro11$ ,  $\Delta sci1_{hyg}$ ,  $\Delta sci1_{hyg}::5'sci1egfp$  compared to growth on SWG (Figure S 8). However, the *pro11* and  $\Delta sci1_{hyg}$  strains grew slightly better under nitrogen starvation conditions (SWG without  $KNO_3$ ) compared to growth on SWG. No obvious growth reduction for the  $\Delta pro11$  strain was detected on SWG without  $KNO_3$  but both strains,  $\Delta pro11$  and the *pro11* strain appeared to produce more areal hyphae than on SWG. The  $\Delta sci1_{hyg}$  strain performed better on SWG supplemented with  $H_2O_2$  and  $CaCl_2$  compared to SWG. Although,  $\Delta pro11$  was reported to grow better under oxidative stress the experiments showed that the strain produced less air mycelium but growth was similar as on regular SWG. Also, growth of *pro11* was not reduced in presence of  $H_2O_2$  as described before but was reduced by SDS compared to the wt and the other tested strains (Bernhards, 2010) (Figure S 8).

## 2.8 SCI1 oligomerizes and interacts with PRO11 and PRO45 in yeast two-hybrid experiments

Using affinity purification and LC/MS, SCI1 was identified as putative interaction partner of PRO11 in this study and as putative interaction partner of PRO45 in a former study (Nordzieke *et al.*, 2015). Thus, yeast two-hybrid experiments were performed to investigate direct SCI1-PRO11 and direct SCI1-PRO45 interaction. A further aim was to identify domains, which are required for physical interaction of SCI1 and PRO11 or PRO45 using fragments of SCI1 and PRO11 or PRO45 (Figure 16 A). Full-length *sci1* and *sci1* fragments were amplified from cDNA and cloned into pGADT7 and pGBKT7 encoding the activation-domain (AD) sequence or the binding-domain (BD) sequence of the transcriptional activator Gal4. Plasmids encoding AD and BD fusion proteins were cotransformed into PJ69-4A and a drop assay was performed. Yeast strains transformed with plasmids encoding the AD fused to the Gal4 interacting protein RanBPM and BD fused to PRO11, PRO45, SCI1 and SCI1 protein fragments grew on SD -Leu, -Trp, -Ade and -His indicating expression of the bait fusion proteins and Y2H competency (Tucker *et al.*, 2009). All constructs used: *pro11*, *pro45*, *sci1* or *sci1* fragments were not self-activating (Figure 16 A).

To this end, different *sci1* constructs fused to the AD or BD sequence were designed and also different *pro11* constructs were used (Figure 16 A). Strains expressing full-length BDSCI1 and full-length ADPRO11 fusion proteins grew on SD -Leu, -Trp, -Ade and -His medium, indicating direct interaction of the two proteins. Unfortunately, BDPRO11 but not BDPRO11 1-110 is self-activating and could not be used to test interaction with ADSCI1 protein derivatives (Bloemendal *et al.*, 2012, Bernhards, 2010) (Figure 16 B).

Strains expressing the fragment ADPRO11 111-281 and BDSCI1-FL grew on selective medium, which indicates that the AAs in position 111-281 of PRO11 are required for the interaction with SCI1 (Figure 16 B). On the other hand, the central part of the SCI1 protein, containing the third CC domain and the AA sequences between the second and third CC domain seems to be most important for interaction with PRO11 (Figure 16 A and B). BDPRO11 1-110 and ADPRO11 111-281 did not interact, which was previously described by Bloemendal *et al.*, 2012. However, the oligomerization of PRO11 via its CC domain was confirmed using ADPRO11-FL and BDPRO11 1-110 (Bloemendal *et al.*, 2012) (Figure 16 B). Yeast strains expressing ADPRO11 111-281, and BDSCI1 121-207 or BDSCI1 121-298 grew very poorly indicating that the fusion proteins might be folded improperly, are instable or lack a protein region stabilizing interaction between PRO11 and SCI1.

## Results

**Figure 16: SCI1, PRO11 and PRO45 interact in a yeast two-hybrid analyses**

**A:** The full-length SCI1, PRO11 and PRO45 protein fragments tested in the Y2H analysis and predicted domains are presented. The position of the AA included in the protein fragments is given and the corresponding predicted domains are indicated. CC: coiled-coil domain (green), CaM: calmodulin-binding domain (yellow), WD: tryptophan-aspartic acid repeats (purple), FHA: forkhead-associated domain (black), TM: transmembrane domain (orange). Representation of PRO11 and PRO45 fragments was modified according to Bloemendal *et al.* (2012) and Nordziede *et al.* (2015). **B:** Plasmids encoding the *Gal4* activating domain (AD) or binding-domain (BD) sequence fused to the respective *sci1*, *pro11* or *pro45* gene fragments were cotransformed into PJ69-4A. Yeast strains (20  $\mu$ L) with and OD<sub>600</sub> of 0.1 were dropped onto synthetic defined medium without, leucine, tryptophan, histidine and adenine (SD-Leu, -Trp, -Ade, -His). Growth indicates interaction of the tested fusion proteins. RanBPM was used as positive control and indicates Y2H competency of the BD-constructs. As negative control, plasmid constructs containing corresponding *sci1*, *pro11* or *pro45* fragments were cotransformed with empty pGADT7 or pGBKT7 plasmids and show no growth indicating no interaction as expected for the negative controls. nd: not determined in this study.

## Results

Also, interaction of SCI1 and PRO45 was verified by Y2H when full-length SCI1 was fused to the AD of the Gal4 transcription factor and either full-length PRO45 or PRO45 $\Delta$ TM were fused to the BD of the Gal4 transcription factor (Figure 16 A and B). Furthermore, the N-terminal region of SCI1 seems to be most important for interaction with PRO45 (Figure 16 B). Besides the direct interaction of SCI1 with PRO45 shown in this study, oligomerization of PRO45 was confirmed but no direct interaction of PRO11 and PRO45 was detected (pers. com. Steffen Nordzieke) (Figure 16 B).

Strains expressing SCI1 full-length proteins ADSCI1-FL and BDSCI1-FL grew on SD -Leu, -Trp, -Ade and -His medium. Thus, the central region of SCI1 (AA 63-207) is required for SCI1 oligomerization (Figure 16 B), which was also shown for its ortholog Far3 in *S. cerevisiae* (Lai 2011). No growth was detectable with any other construct (Figure 16 B).

### 2.8.1 The central region of SCI1 complements the sterile phenotype of $\Delta$ sci1<sub>hyg</sub>

The central region of SCI1 was shown to be important for oligomerization of SCI1 in Y2H experiments and for interaction with PRO11 (Figure 16 A).

Thus, *S. macrospora* plasmids containing the endogenous *sci1* promoter, *sci1* fragments encoding the AA region 63-207, 121-207, 121-298 and 208-298 and the heterologous *trpC* terminator in the pRSnat backbone were transformed into the  $\Delta$ sci1<sub>hyg</sub> mutant. The fragments used are presented in figure 17 A. Also after prolonged incubation of 3 weeks no perithecia were detected for  $\Delta$ sci1<sub>hyg</sub>::5'*sci1*<sub>121-207</sub>,  $\Delta$ sci1<sub>hyg</sub>::5'*sci1*<sub>121-298</sub> and  $\Delta$ sci1<sub>hyg</sub>::5'*sci1*<sub>208-298</sub> (Figure 17 B).

In contrast, the  $\Delta$ sci1<sub>hyg</sub>::5'*sci1*<sub>63-207</sub> strain formed perithecia in limited numbers containing asci with ascospores but only after a prolonged time of 3 weeks after inoculation (Figure 17 B). Thus, the *sci1* fragment encoding the central region of SCI1 (AA 63-207) weakly complemented the  $\Delta$ sci1<sub>hyg</sub> phenotype. The reduced ability or inability to complement the sterile phenotype might result from improper expression or folding of the truncated proteins. However, the results are consistent with the Y2H experiments showing SCI1 oligomerization and the requirement of the central region of SCI1 for interaction with PRO11 (Figure 16 B, Figure 17 B).

## Results

**Figure 17: Complementation studies with SCI1 fragments transformed into  $\Delta sci1_{hyg}$**

**A:** Overview of *sci1* fragments used for complementation studies in  $\Delta sci1_{hyg}$ . **B:** The central region of *sci1* encoding the AA region 63-207 complemented the  $\Delta sci1_{hyg}$  sterile phenotype weakly and mature perithecia were formed. However, perithecia containing asci with ascospores were detected 3 weeks after inoculation on SWG medium. The other SCI1 fragments, 5'*sci1*<sub>121-207</sub>, 5'*sci1*<sub>121-298</sub> and 5'*sci1*<sub>208-298</sub> did not complement the sterile *sci1* deletion strain and perithecia were never detected. Scale bars as indicated.

### 2.9 PRO11 was enriched in SCI1eGFP pull-downs

As SCI1 was identified in PRO11 pull-downs coupled to LC/MS (Figure 8, Table S 1, Table S 3) and both proteins were shown to interact in Y2H experiments (Figure 16 B), SCI1 was used as bait to search for putative interaction partners in *S. macrospora*. The total protein content from mycelium of the  $\Delta sci1_{hyg}::sci1egfp$  strain was isolated and three independent SCI1eGFP pull-down and LC/MS analyses (SCI1eGFP MS1, SCI1eGFP MS2 and SCI1eGFP MS3) were performed as described in section 2.1.1 and 2.1.2 for PRO11 and SmMOB3 pull-downs (Table 8). In total 1029/887, 1167/893 and 1319/881 proteins were identified with the MaxQuant/Perseus and the Proteome Discoverer™ software, respectively.

MaxQuant/Perseus data analysis, derived from SCI1eGFP pull-downs and LC/MS is presented in a heat map (Figure 18 A). Also, a 2-sample t-test was performed using signal intensities to identify and discriminate significantly enriched candidates in SCI1eGFP pull-downs from unspecific background (Figure 18 B). The bait protein SCI1eGFP and PRO11 were highly enriched in all three pull-downs. Simultaneously, dynein heavy chain (SMAC\_00761) was enriched with SCI1eGFP in all three pull-down experiments and detected with MaxQuant/Perseus. MaxQuant/Perseus identified PRO22 in all three SCI1eGFP pull-downs. Also, a putative glutamate synthase (SMAC\_08095) was enriched but was not detected with the Proteome Discoverer™ software. Other candidates

## Results

matching the criteria, enriched in at least two pull-downs and not enriched in the negative control were identified and are marked in red in figure 18 A. Two of them, a putative serine-threonine protein kinase (SMAC\_02146) and a putative aminotransferase (SMAC\_07234) were also identified with the Proteome Discoverer™ software (Figure 18 ,Table S 4).

**Figure 18: LC/MS data from SCI1eGFP pull-downs coupled to LC/MS and represented in a heat map as well as in volcano plot**

The results of the GFP-Trap using SCI1eGFP as bait and LC/MS are represented in a heat map and in a volcano plot. **A:** The heat map shows the results of the SCI1eGFP-LC/MS1, 2 and 3 with the corresponding GFP negative control (1, 2 and 3). Signal intensities correlate with the abundance of the peptides detected. White represents low signal intensities and dark blue indicates high signal intensities. In total, 1029, 1167 and 1319 proteins were identified with MaxQuant/Perseus. Proteins specifically enriched are presented in the heat map. Signal intensities for the bait protein with the locus tag SMAC\_05559 (SCI1) were high in all LC/MS experiments. PRO11 (SMAC\_08794) was highly enriched in LC/MS1, 2 and 3. PRO22 (SMAC\_02580) and dynein heavy chain (SMAC\_00761) were also enriched in all three LC/MS experiments. **B:** The volcano plot represents the results of a statistical 2 sample t-test. Putative SCI1 interaction partners have a  $p$ -value < 0.1 and a t-test difference value of < -3 and are marked in red in the heat map.

In contrast, PRO22 was only discovered in one LC/MS experiment with the Proteome Discoverer™ software. Among others, proteins predicted to be involved in vacuolar transport (SMAC\_04234

and SMAC\_08299), a putative nucleoporin (SMAC\_00744), a putative chitin synthase (SMAC\_03109), a putative protein involved in ER to Golgi transport (SMAC\_06397) as well as a putative protein involved in transport to and out of the *trans*-Golgi (SMAC\_03125) were identified with the Proteome Discoverer™ (Table S 4).

## 2.10 Functional conservation of SCI1

Small coiled-coil proteins were detected in STRIPAK complexes of fungi and animals (section 1.1 - 1.3.1) (Table 1). Although the proteins are barely conserved among phyla it was of interest if their function might be conserved (Figure S 3).

### 2.10.1 Mammalian FGFR1OP2 and yeast Far3/7 do not complement the sterile phenotype of $\Delta sci1_{hyg}$

To investigate the functional conservation of mammalian *FGFR1OP2* and yeast *Far3/7*, plasmids encoding rat and human *FGFR1OP2* and *S. cerevisiae FAR3* and *FAR7* DNA were transformed into the *S. macrospora* strain  $\Delta sci1_{hyg}$ . Rat wt *Fgfr1op2*, human wt *FGFR1OP2* and human single nucleotide polymorphism 1 (SNP1) *FGFR1OP2* (*FGFR1OP2\_SNP1*) genes derived from cDNA (Lin *et al.*, 2010) were set under the control of the *N. crassa ccg1* promoter and the terminator of the anthranilate synthase gene of *A. nidulans trpC* in the pRSnat background. The plasmids pFGFR1OP2Rn, pFGFR1OP2Hs, pFGFR1OP2Hs\_SNP1, pFar3HA and pFar7FLAG were transformed into  $\Delta sci1_{hyg}$ . However, none of the constructs complemented the sterile  $\Delta sci1_{hyg}$  *S. macrospora* strain.

### 2.10.2 SCI1 interacts with Far3 and Far7 but not with Far8 in Y2H experiments

Despite the fact that, *Far3* and *Far7* could not complement the sterile phenotype of  $\Delta sci1_{hyg}$  it was of interest if *SCI1* can interact with the *S. cerevisiae* proteins *Far3*, *Far7* and with the striatin ortholog *Far8* in Y2H experiments. In *S. cerevisiae*, the interaction of *Far3* and *Far7* is the prerequisite for interaction with *Far8* (Kemp & Sprague, 2003, Pracheil & Liu, 2013). Furthermore, *Far3* self-interacts via its central region (Lai *et al.*, 2011). To test interaction of *SCI1* with *Far3*, *Far7* and *Far8*, *FAR3*, *FAR7* and *FAR8* were amplified from PJ69-4A gDNA and were cloned into pGADT7. Plasmids described before encoding the *SCI1* full-length protein and *SCI1* fragments were derived from pGBKT7 (BD) and the combinations used in the Y2H analyses are presented in figure 19 A. A

## Results

Y2H drop assay was performed and interaction of ADFar3, ADFar7 and ADFar8 fusion proteins was tested with BDSCI1-FL and BDSCI1 protein fragments (Figure 19 A). Negative and positive controls are presented in figure 19 B and figure 9 S.

**Figure 19: Yeast two-hybrid drop test of SCI1, Far3, Far7 and Far8**

**A:** Constructs of *sci1*, *FAR3*, *FAR7* and *FAR8* were fused to the Gal4 activating domain (AD) or binding-domain (BD) sequence and the respective plasmids were cotransformed into PJ69-4A. CC: coiled-coil domain (green)

**B:** 20  $\mu$ L ( $OD_{600} = 0.1$ ) of each yeast strain was dropped on selective medium. Growth of yeasts indicating interaction of the tested fusion proteins was detected on synthetic defined medium without, leucine, tryptophan, histidine and adenine (SD –Leu, -Trp, -Ade, -His). RanBPM was used as positive control and indicates Y2H competency of the BD constructs. Constructs containing corresponding fragments were cotransformed with empty pGADT7 or pGBKT7 plasmids and showed no growth indicating no interaction as expected for the negative controls.

Although Far3 and Far7 interact with the striatin ortholog Far8 in *S. cerevisiae* no interaction could be detected between the ADFar8 and BDSCI1-FL or BDSCI1 fragments (Kemp & Sprague, 2003, Pracheil & Liu, 2013) (Figure 19 B). Nevertheless, SCI1 and Far7 can interact via the N-terminal region of SCI1 and SCI1 and Far3 can interact via the central region of SCI1 (Figure 19 B). Remarkably, the yeast strain expressing the truncated BDSCI1 63-207 fragment and the ADFar3 construct grew better than the strain with the BDSCI1-FL and ADFar3 constructs, which might indicate that the very central region of SCI1 is most important for the interaction with Far3. The

## Results

SCI1 protein (298 AA) is about one third bigger than the Far3 protein (204 AA). Therefore, the full-length SCI1 protein might hamper interaction between SCI1 and Far3 (Figure 9, Figure 19).

Taken together, these results are consistent with the results from Lai *et al.* (2011). The authors reported that Far3 self-associates through its central region. Thus, the function of the central region of SCI1 and Far3 seems to be conserved in *S. macrospora* and *S. cerevisiae* and allows interaction of the yeast Far3 and *S. macrospora* SCI1 protein.

### 2.11 SCI1 and PRO11 colocalize at the nuclear envelope

In fungi, STRIPAK components were found to localize at the nuclear envelope (NE) (Dettmann *et al.*, 2013, Nordzieke *et al.*, 2015, Wang *et al.*, 2010). PRO11 is a STRIPAK complex protein, which interacts with SCI1. Therefore, fluorescence microscopy was used to investigate localization of the SCI1eGFP fusion protein and synthesis of the SCI1eGFP fusion protein was shown by Western blot (Figure S 11 A). The fertile  $\Delta sci1_{hyg}::sci1egfp$  strain was crossed to the wt::h2btdTomato strain synthesizing TdTomato-tagged histone H2B (Nordzieke *et al.*, 2015), to visualize the nuclei within the hyphae of *S. macrospora* (Figure 20 A). Also, localization of eGFP-tagged PRO11 in *S. macrospora* hyphae was performed with fluorescence microscopy (Figure 20 B). To do this, the sterile  $\Delta pro11$  strain was complemented with an *hapro11egfp* construct (Figure S 11 C) and the fertile  $\Delta pro11::hapro11egfp$  strain was crossed with wt::h2btdTomato to visualize the nuclei. The proteins SCI1eGFP and HAPRO11eGFP localized to roundish structures, which were shown to be nuclei using TdTomato-tagged histone H2B (Figure 20 A and B). In other fungi, striatin orthologs were reported to localize to the NE but no colocalization of striatin orthologs and proteins known to localize to the NE was performed to date (Dettmann *et al.*, 2013, Wang *et al.*, 2010, Zhang *et al.*, 2017). Thus, it was necessary to clarify if SCI1 localizes to the NE.

In *U. maydis*, the protein pore membrane 152 (POM152) was described to localize to the NE (Theisen *et al.*, 2008). Using BLASTP search the ortholog of UmPOM152 in *S. macrospora* with the locus tag SMAC\_03501 was identified and named SmPOM152. The amino-acid sequence identity between UmPOM152 and SmPOM152 was 27% with an E-value of  $3 \times 10^{-87}$ . A plasmid conferring nourseothricin resistance was generated encoding SmPOM152 fused to eGFP.

## Results

**Figure 20: Localization of SCI1 and PRO11 proteins fused to fluorescent tags visualized in vegetative hyphae of *S. macrospora***

**A:** Localization of SCI1eGFP and H2BTdTomato **B:** Localization of HAPRO11eGFP and H2BTdTomato **C:** SCI1DsRED and the nuclear basket protein SmPOM152 fused to eGFP colocalized at the nuclear envelope. **D:** SCI1DsRED and HAPRO11eGFP colocalize at the nuclear envelope. Scale bars: 20  $\mu$ m.

## Results

The  $\Delta sci1_{hyg}$  strain was transformed with the *Smpom152egfp* construct under the control of the promoter of the *ccg1* gene from *N. crassa* and the synthesized fusion protein SmPOM152eGFP localized to punctiform structures at the NE (Figure 20 C, Figure S 11 E).

The  $\Delta sci1_{hyg}$  strain was complemented with a *sci1Dsred* construct expressing C-terminally DsRED-tagged SCI1 (Figure S 11 B) and crossed to the  $\Delta sci1_{hyg}::Smpom152egfp$  strain. Finally, SCI1DsRED was colocalized with SmPOM152eGFP showing that SCI1 localizes at the NE (Figure 20 C).

Also, PRO11 and SCI1 were colocalized in *S. macrospora*. The double deletion strain  $\Delta sci1_{hyg}\Delta pro11$  was complemented with a *sci1Dsred* and an *hapro11egfp* construct and nourseothricin and hygromycin resistant strains were selected. The  $\Delta sci1_{hyg}\Delta pro11::sci1Dsred+hapro11egfp$  strain was able to produce mature perithecia filled with ascospores indicating that both constructs were functional. The presence of HAPRO11eGFP and SCI1DsRED fusion proteins in the  $\Delta sci1_{hyg}\Delta pro11::sci1Dsred+hapro11egfp$  strain was verified by Western blot (Figure S 11 D) and in fluorescence microscopy HAPRO11eGFP and SCI1DsRED colocalized at the NE (Figure 20 D, Figure S 12). SCI1eGFP and HAPRO11eGFP also localized to small punctiform structures dispensed in the cytoplasm and to thread-like structures in contact with the NE (Figure S 12).

### 2.12 Analysis of cellular components in $\Delta sci1$

STRIPAK complexes of mammals, of fission yeast and of the baker's yeast are connected to the nuclear envelope/nuclear trafficking, the endoplasmic reticulum (ER), mitochondria, actin polymerization, septation and endosome trafficking (Baryshnikova *et al.*, 2010, Byers *et al.*, 2009, Chang & Gould, 2000, Frost *et al.*, 2012, Lisa-Santamaría *et al.*, 2012, Pracheil & Liu, 2013, Singh *et al.*, 2011). It was also suggested that the STRIPAK in *S. macrospora* is involved in vesicular transport (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012). Therefore, fluorescent marker proteins were used to visualize nuclear transport, mitochondria, ER, actin polymerization/septation and endosomal transport in the *sci1* deletion background compared to the wt background.

#### 2.12.1 *sci1* deletion does not interfere with nuclear transport

DAPI stain was applied to visualize nuclei in *S. macrospora*. Unfortunately, DAPI is solved in formaldehyde-containing buffer, which negatively influences the vitality of *S. macrospora* hyphae, alters appearance of hyphae and hyphal content and finally destroys hyphae. When stained with

## Results

DAPI, hyphae of  $\Delta sci1_{hyg}$  appeared to be more fragile than wt hyphae. Also, a reduced amount of formaldehyde in the DAPI stain interfered with hyphal vitality and more rapidly destroyed hyphae of the mutant strain than of the wt.

Therefore, using fluorescence microscopy, nuclei were visualized by TdTomato-tagged histone 2 b and movement of nuclei was observed in living hyphae of wt *S. macrospora*. However, no difference was detected between nuclei of wt::h2btdTomato or  $\Delta sci1_{hyg}$ ::h2btdTomato (Video 1, Video 2). Nuclei in both strains moved in all directions, forwards as well as backwards. In both strains, nuclei were roundish or oval and sometimes had an elongated structure with a neck-like shape (Figure S 13 A). These nuclei seemed to be drawn by their necks and some crawl through the hyphae (Video 2).

Nuclei in  $\Delta sci1_{hyg}$ ::h2btdTomato hyphae appeared to be herded together but  $\Delta sci1_{hyg}$  shows a strong vegetative growth defect, which might dam up nuclei (Figure S 13 A). Thus, nuclear shape, transport and nuclear distribution seems not to be affected in  $\Delta sci1_{hyg}$ ::h2btdTomato.

### 2.12.2 Mitochondria appeared similar in the wt and in *sci1* deletion strains

Mitochondria were visualized with the fusion construct pMito-DsRED encoding the N-terminal mitochondrial signal sequence of carbonic anhydrase 2 (CAS2) fused to the *Dsred* sequence (Elleuche & Pöggeler, 2008). The plasmid pMito-DsRED was transformed into the wt and the  $\Delta sci1_{hyg}$  strain and fluorescence microscopy was performed with clones conferring nourseothricin resistance. Mitochondria were similarly distributed within the cytoplasm in hyphae of both strains, wt::mitoDsred and  $\Delta sci1_{hyg}$ ::mitoDsred (Figure S 13 B). Also, movement and shape of mitochondria were similar in hyphae of wt::mitoDsred and  $\Delta sci1_{hyg}$ ::mitoDsred (Video 3, Video 4).

### 2.12.3 Endoplasmic reticulum in the $\Delta sci1_{hyg}$ background appears normal

The plasmid pDsREDKDEL encoding the N-terminal signal sequence for cotranslational insertion into the ER from the ER protein PRO41 and the C-terminal ER retention signal KDEL fused to *Dsred* was transformed into the  $\Delta sci1_{hyg}$  strain and into *S. macrospora* wt strain to visualize the ER in the hyphae (Nowrousian *et al.*, 2007). Clones with nourseothricin resistance were selected and investigated with fluorescence microscopy. Thread-like structures sometimes surrounding roundish structures, which might be nuclei, were observed in both strains, wt::DsredKDEL and  $\Delta sci1_{hyg}$ ::DsredKDEL (Figure S 13 C). Additionally, punctiform structures were observed, which might be accumulation of missfolded DsREDKDEL fusion proteins (Nowrousian *et al.*, 2007). Taken

together, the DsREDKDEL fusion protein localized to thread-like structures in hyphae of wt::DsredKDEL and  $\Delta sci1_{hyg}$ ::DsredKDEL.

#### 2.12.4 Actin polymerization and septum formation is not impaired in the *sci1* background

Previously, intercalary septum formation in ascogonia of *S. macrospora* was shown to be abolished in the pro22 mutant and in the  $\Delta Smp2Ac1$  mutant (Beier *et al.*, 2016, Bloemendal *et al.*, 2010). Calcofluor white stain (CFW) was applied to stain cell walls and septae in ascogonia of wt,  $\Delta sci1_{hyg}$ ,  $\Delta sci1_{hyg}$ ::5'sci1egfp, pro11 and  $\Delta pro11$ . All strains formed intercalary septae in ascogonia and also in vegetative hyphae (Figure 21 A).

The STRIPAK complex in mammals and yeasts was reported to be involved in actin polymerization therefore actin polymerization was investigated in *S. macrospora* (Bai *et al.*, 2011, Baryshnikova *et al.*, 2010, Chen & Hsueh, 2012, Goudreault *et al.*, 2009, Gupta & McCollum, 2011, Pracheil *et al.*, 2012). For visualization of F-actin in *S. macrospora*, the plasmid pAL4-Lifeact (Lichius & Read, 2009) was transformed into the wt and the  $\Delta sci1_{hyg}$  strain and nourseothricin resistant strains were selected. The plasmid pAL4-Lifeact encodes a peptide of 17 AA derived from the actin-binding protein 140 (Abp140) of *S. cerevisiae* fused to the monomeric red fluorescent protein TagRFP (Riedl *et al.*, 2008, Lichius & Read, 2009). In filamentous fungi, actin accumulates along the cell wall, polymerizes and contracts to form a ring-like structure (Berepiki *et al.*, 2010) (Figure 21 B).

Septae were formed in young vegetative hyphae of wt::lifeact-tagrfp one after the other as the hyphae grew (Figure 21 B, Video 5). Signals for actin were distributed in a defined region along the cell wall. Then, actin polymerized in a hill-like structure, which most likely represented the contraction of the actin ring preceding septum formation. However, the signal for the TagRFP fluorophore in  $\Delta sci1_{hyg}$  background was weaker than in the wt background and bleaching occurred faster than in the wt (Video 6). CFW staining performed with 5% potassium hydroxide decreased the vitality of hyphae, especially of the  $\Delta sci1_{hyg}$  strain and actin polymerization could not be properly visualized. F-actin patches and cables were detected in old hyphae of both strains wt::lifeact-tagrfp and  $\Delta sci1_{hyg}$ ::lifeact-tagrfp (Figure 21 B).

## Results

**Figure 21: Septation of ascogonia, F-actin polymerization and localization in *S. macrospora pro11* and *sci1* deletion and wt backgrounds**

**A:** Intercalary septae in ascogonia were visualized with calcofluor white (CFW) stain. **B:** Actin polymerization in young hyphae visualized by lifact-TagRFP. Actin accumulates along the call wall, the actin ring contracts and the septum is formed. Also, actin filaments and patches in old hyphae are shown. Scale bars: 20  $\mu$ m.

### 2.12.5 Visualization of early and late endosomal marker proteins in the wt and the *sci1* deletion background

In mammals, the STRIPAK components striatin and MOB3 (phocein) were reported to be involved in endocytosis and vesicular transport (Baillat *et al.*, 2002, Baillat *et al.*, 2001, Benoist *et al.*, 2006). Similar, in the fungus *S. macrospora*, *in silico* analysis suggests a role of SmMOB3 in vesicular traffic and endocytosis (Bernhards & Pöggeler, 2011). In general, it is thought that endocytosis in filamentous fungi takes place mainly in the hyphal tip. In this model early endosomes (EEs) move to the hyphal tip by kinesin-3 to exchange membrane components with the hyphal tip. Whereas, dynein is thought to mediate retrograde transport of EEs (Steinberg, 2007b). Recently, an early and

a late endosomal marker were published for the wheat pathogenic ascomycete *Zytopetoria tritici* (Zt) (Kilaru et al., 2015).

The small GTPase Rab5 localizes to EEs. EEs mature into late endosomes (LEs) containing the small GTPase Rab7 and finally deliver their content to vacuoles for recycling (Kilaru et al., 2015). The plasmids pHEGFPRAB5 and pHEGFPRAB7 conferring hygromycin resistance were kindly provided by Kilaru et al. (2015) and were transformed into the *S. macrospora* wt and into the verified  $\Delta sci1_{nat}$  strain (Figure S 14). The  $\Delta sci1_{nat}$  strain was sterile and hyphal fusion defective as described for  $\Delta sci1_{hyg}$  (data not shown). Clones were selected for hygromycin resistance and fluorescence microscopy was performed. The fluorescent compound 7-amino-4-chloromethyl-coumarin (CMAC) was used to stain the acidic lumen of vacuoles (Cole et al., 1997, Cole et al., 1998). Vacuolar proteases act on CMAC and stain vacuoles bright blue.

### **2.12.5.1 The early endosome marker eGFPZtRab5 accumulates in hyphae of the $\Delta sci1_{nat}$ background**

The N-terminally eGFP-tagged EE marker ZtRab5 visualized very small, punctiform structures moving fast in the apical region of the hyphae in the wt::egfpZtrab5 strain. Additionally, medium-sized punctiform structures moved in different speed and in all directions through the hyphae. Some of them were rather static, whereas others moved rapidly forward and backwards. These punctiform structures merged and split away from each other continuously (Video 7). In the subapical region of the wt::egfpZtrab5 strain signals for eGFPZtRAB5 weakly stained filamentous/tubular structures, which might represent tubular vacuoles (Figure 22 A).

Additionally, free eGFP from the eGFPZtRab5 fusion protein (Figure S 16) was detected in the vacuoles of the wt strain (Figure 22 B). In contrast, free eGFP in the wt::egfp control strain is located to the cytoplasm (Figure S 15 A).

Localization of eGFPZtRAB5 in the hyphae of the  $\Delta sci1_{nat}$ ::egfpZtrab5 strain was different than in the wt::egfpZtrab5 strain. The signals detected appeared much stronger and three types (1, 2 and 3) of structures were detected in hyphae of  $\Delta sci1_{nat}$ ::egfpZtrab5. Tiny vesicles (1) were observed just behind the hyphal tip moving along filamentous-like structures into subapical region of the hyphae. The vesicles moved like beads on a string suggesting transport along tubules or actin filaments (Video 8).

## Results

In  $\Delta sci1_{nat}::egfpZtrab5$ , big punctiform structures (2) accumulated in the apical region of hyphae (Figure 22 A) and appeared to incorporate medium sized punctiform structures. These big structures moved marginally with the cytoplasmic flow (Video 9). In  $\Delta sci1_{nat}::egfpZtrab5$  hyphae also medium sized punctiform structures (3) were detected (Figure 22 A and B) both moving in different velocities (Video 9). The big punctiform structures in the apical region of  $\Delta sci1_{nat}::egfpZtrab5$  hyphae might represent either accumulated EEs or vesicles fusing to form giant EEs or fusing to other rather static compartments.

**Figure 22: Localization of eGFPZtRab5 in *S. macrospora* wt::egfpZtrab5 and  $\Delta sci1_{nat}::egfpZtrab5$  strain**  
Localization of the N-terminally eGFP-tagged ZtRab5 protein was determined in the *S. macrospora* wt and in the *sci1* deletion background. The eGFPZtRab5 fusion protein was localized in **A**: young hyphae and in **B**: old hyphae. Vacuoles were stained with CMAC. Scale bar size: 20  $\mu$ m.

Roundish regions without fluorescence, presumably representing nuclei, were distinguishable in hyphae of  $\Delta sci1_{nat}::egfpZtrab5$ . The accumulated eGFPZtRab5 signal in the  $\Delta sci1_{nat}$  background allowed observation of “cloudy” structures moving around the roundish regions (Video 9).

In contrast to the wt::egfpZtrab5 strain no free eGFP was observed in the vacuoles of  $\Delta sci1_{nat}::egfpZtrab5$  but on several locations fluorescent signals for eGFP appeared like clouds in the cytoplasm next to vacuoles (Figure 22 B). In the control strain wt::egfp free eGFP was localized to the cytosol (Figure S 15 A).

To test whether endocytosis is impaired in  $\Delta sci1_{nat}::egfpZtrab5$  and in other *sci1* background strains, hyphae were stained with the amphiphilic dye FM4-64 (Figure S 15 B). FM4-64 stains lipid-

## Results

rich membranes (Betz *et al.*, 1992, Betz *et al.*, 1996) and is used to investigate endocytosis and endosome to vacuole transport in filamentous fungi (Fischer-Parton *et al.*, 2000, Hoffmann & Mendgen, 1998, Peñalva, 2005, Steinberg *et al.*, 1998, Vida & Emr, 1995). Staining of  $\Delta sci1$  and the wt background strains showed that after 20 minutes FM4-64 was distributed within the hyphae (Figure S 15 B). Therefore, endocytosis and vesicle transport is not completely impaired in  $\Delta sci1$ . Hence, the accumulation of eGFPZtRab5 might indicate a defect in secretion resulting in accumulation of eGFPZtRab5 in  $\Delta sci1_{nat}$ . However, the lack of free eGFP in vacuoles of  $\Delta sci1_{nat}::egfpZtrab5$  but not of  $wt::egfpZtrab5$  might also indicate a defect in degradation processes.

### **2.12.5.2 The late endosome marker eGFPZtRab7 in the $\Delta sci1_{nat}$ background visualizes abnormal vacuolar morphology and behavior**

As EEs mature to late endosomes (LE) marked by the protein Rab5, it was also of interest if LE appearance and transport are altered in the *sci1* deletion background. Therefore, a wt strain and a  $\Delta sci1_{nat}$  strain were generated, synthesizing the N-terminally eGFP tagged LE marker protein ZtRab7 (Figure S 16).

In  $wt::eGFPZtRab7$  *S. macrospora* hyphae, eGFPZtRab7 visualized small-punctiform structures in the apical region melting together or splitting away from tubular structures (Figure 23 A)(Video 10). These, tubular structures most likely represent vacuolar tubules, which were described to exist in *S. macrospora* (Bloemendal *et al.*, 2010). In filamentous fungi, *N. crassa*, *A. nidulans* and *Pisolithus tinctorius*, tubular vacuoles were described to mediate transport along microtubules in young hyphae (Bowman & Bowman, 2010, Hickey & Read, 2009, Bowman *et al.*, 2015).

Rab7 orthologs fused to eGFP in hyphae of *Z. tritici* and *A. nidulans* stained punctiform structures but nothing was reported about tubular structures (Abenza *et al.*, 2012, Kilaru *et al.*, 2015).

Investigating young to middle old  $wt::eGFPZtRab7$  hyphae dynamic vacuoles fusing and splitting again were observed (Figure 23 B). Whereas, middle old hyphae contained spherical and elongated vacuoles with some free eGFP inside (Figure 23C). Spherical vacuoles with free eGFP were detected in middle old to old hyphae (Figure 23 D). Interestingly, a similar sequence of hyphal components as observed for eGFPZtRab7 in *S. macrospora*  $wt::eGFPZtRab7$  was visualized by fluorescence-tagged calcium transporter proteins, SERCA-type  $Ca^{2+}$  ATPases (NCAs) and the vacuolar protein

## Results

VAM-3 in *N. crassa* (Bowman *et al.*, 2009). Last but not least, in old wt::eGFPZtRab7 hyphae, small roundish structures without an eGFP signal were detected (Figure 23 E).

**Figure 23: Localization of eGFPZtRab7 in *S. macrospora* wt::eGFPZtRab7 and  $\Delta sci1_{nat}::eGFPZtRab7$  strain**  
 Localization of the eGFPZtRab7 protein in **A**: young hyphae (apical region) **B**: young hyphae, (subapical region) **C**: middle old hyphae **D**: middle old to old hyphae and **E**: old hyphae of *S. macrospora* wt::eGFPZtRab7 and the  $\Delta sci1_{nat}::eGFPZtRab7$  strain. Vacuolar structures with free eGFP and without free eGFP were detected. Vacuoles with a weak eGFP signal are shown in **C** and are marked with asterisks. Scale bar size: 20  $\mu m$

Small and big vacuoles with less or more free eGFP were stained blue using CMAC to stain the acidic lumen of vacuoles. However, small roundish structures without eGFP signals could not be stained by CMAC in hyphae of the wt::eGFPZtRab7 strain (Figure S 17 A). In *Z. tritici* and *A. nidulans* LEs visualized by eGFPZtRab7 associated with CMAC stained vacuoles, which also contained eGFPZtRab7

## Results

associated to the membrane (Abenza *et al.*, 2012, Kilaru *et al.*, 2015). At least in *A. nidulans*, LEs were localized to young hyphae and in both studies LEs were suggested to fuse with vacuoles (Abenza *et al.*, 2012, Kilaru *et al.*, 2015). Therefore, in *S. macrospora* small-punctiform structures, fusing with most likely tubular vacuoles in young hyphae might represent LEs.

In young hyphae of  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$ , small punctiform structures, presumably LEs, melted to short tubular structures, which appeared more distributed than in the wt (Figure 23 A and B). Additionally, small vacuoles moving marginally were observed in young hyphae of  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$  (Video 11). In *P. tinctorius*, vacuoles are in close proximity to microtubules and microtubules were considered to determine vacuole morphology and motility (Hyde *et al.*, 1999). Thus, transport of vacuoles along microtubules or connection to microtubules might be disturbed in  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$  compared to wt hyphae (Figure 23 A, Video 11). Vacuoles in middle old hyphae were similar to vacuoles detected in wt but the free eGFP signal appeared to be slightly reduced (Figure 23 C). Also, in middle old to old hyphae spherical vacuoles with free eGFP (reduced compared to wt) were detected showing bright green fluorescence at contact sides of vacuoles (Figure 23 D). The vacuoles in old  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$  hyphae appeared bigger and more irregular than in the wt and were brightly stained by CMAC (Figure 23 E, Figure S 15 B).

In sum, large vacuoles without an eGFP signal were frequently detected in  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$  but were rarely seen in the wt background. However, old wt hyphae are located to the center of the mycelium, which is difficult to investigate because of its dense hyphal growth. The regions in which LEs, tubular structures and vacuoles were detected was highly compressed in  $\Delta\text{sci1}_{\text{nat}}::\text{eGFPZtRab7}$  strain compared to the wt::eGFPZtRab7 strain. Especially, small vacuolar structures, spherical vacuoles and vacuoles without free eGFP are much closer to the growing tip of the hyphae than in the wt strain (Figure 23 B). This pre-aged appearance of young hyphae might be caused by the severe vegetative growth defect of  $\Delta\text{sci1}$  or might be caused by disturbed vacuole-microtubule connection resulting in a slow growth phenotype.

### 3. Discussion

The conservation of core STRIPAK orthologs (Table 1) between fungi and mammals suggests one or more similar functions among species but accessory proteins in higher eukaryotes indicate additional functions of the respective STRIPAK complexes.

The Far complex in *S. cerevisiae* synchronizes mating cells allowing enough time for cell to cell fusion before karyogamy takes place and thus regulates sexual reproduction, a process found in higher eukaryotes (Kemp & Sprague, 2003). The SIN in *S. pombe* and the Far complex in *S. cerevisiae* are connected to actin-ring constriction and actin polymerization required for cytokinesis and for cell to cell fusion (Baryshnikova *et al.*, 2010, Pracheil *et al.*, 2012, Singh *et al.*, 2011). Likewise, in the filamentous ascomycete *S. macrospora*, the SmSTRIPAK complex controls cell fusion and is required for vegetative growth and sexual development (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004). However, the underlying molecular mechanisms are unknown. Mature fruiting-body formation is the only way of *S. macrospora* reproduction and generation of sexually derived ascospores is blocked in SmSTRIPAK deletion mutants (Lord & Read, 2011, Pöggeler *et al.*, 1997, Teichert *et al.*, 2014). Thus, the presence of a functional STRIPAK complex is essential during development of *S. macrospora*.

*S. macrospora*, likewise the fruit fly and mammals contains core STRIPAK components and associated proteins, indicating that the SmSTRIPAK might be involved in many different processes (Table 1). In *D. melanogaster*, the dSTRIPAK regulates apoptosis and controls tissue size as well as dorsal closure in embryos (Chen *et al.*, 2002). In mammals, the STRIPAK complex functions in cell-cycle control, apoptosis, cell migration, vesicular traffic, development of neurons, and was connected to cardiac diseases, neuronal diseases and cancer (Bai *et al.*, 2011, Baillat *et al.*, 2001, Bartoli *et al.*, 1999, Breitman *et al.*, 2008, Castets *et al.*, 1996, Chen & Hsueh, 2012, Grand *et al.*, 2004, Hwang & Pallas, 2014, Ishikawa *et al.*, 2012, Lin *et al.*, 2010, Meurs *et al.*, 2010). Therefore, investigating STRIPAK complex components in *S. macrospora* will help to understand the cellular functions in higher eukaryotes, controlled by the STRIPAK complex.

In this study, the yet undescribed protein SCI1 was enriched in PRO11 pull-downs and was identified by LC/MS. A main question of this study was, if SCI1 is a STRIPAK complex component in *S. macrospora*. Also function and subcellular localization of SCI1 was investigated and the spatial-temporal localization of cellular components in the *sci1* deletion strain with the wt were compared.

This study connects the SmSTRIPAK to the Golgi and vesicular traffic arguing for a dynamic SmSTRIPAK complex mediating very complex processes like hyphal fusion and sexual development in *S. macrospora*.

### 3.1 SCI1, a new PRO11 interaction partner was identified in *S. macrospora*

In mammals, striatins act as B'' regulatory subunits of the protein phosphatase PP2A and as scaffolding proteins in the STRIPAK complex to bring STRIPAK components together (Goudreault *et al.*, 2009, Moreno *et al.*, 2000). In the STRIPAK complex of *S. macrospora* (SmSTRIPAK), the striatin ortholog PRO11 seems to be a central component of the SmSTRIPAK complex (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Pöggeler & Kück, 2004). Deletion of *pro11* results in a strain producing only rudimentary ascogonia, and representing the most severe phenotype compared to strains lacking other SmSTRIPAK complex genes, indicating a central role in the function of the SmSTRIPAK complex (Bernhards, 2010). PRO11 directly interacts with the kinase activator SmMOB3 (Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012). Therefore, PRO11 and SmMOB3 were used as baits in pull-down experiments coupled to LC/MS to identify potential interaction partners of the two SmSTRIPAK complex members.

To analyze the LC/MS data, two programs MaxQuant/Perseus and the Proteome Discoverer™ were applied. MaxQuant/Perseus allows identification of peptide precursors, but label-free quantification (LFQ) analysis and independent replicates generate data with different qualities.

The samples applied to LC/MS were very heterogeneous and more proteins were identified with MaxQuant/Perseus using LFQ than with the Proteome Discoverer™ (Table 11, Table 12).

The criteria were stringent to distinguish between enriched proteins and unspecific background. In sum, analysis of the LC/MS data with MaxQuant/Perseus identified known interaction partners of PRO11 and SmMOB3 and the new putative PRO11 interaction partner SCI1 with very high confidence (Figure 8, Figure S 1).

The LC/MS data was also evaluated based on the sum of spectral counts using the Proteome Discoverer™ software. However, in complex samples a peptide precursor might not be selected by the mass spectrometer for fragmentation and a protein might not be detected with the Proteome Discoverer™ software. In general, less proteins were identified with the Proteome Discoverer™ than with MaxQuant/Perseus software (Table 11, Table 12) and the criteria were less

stringent. Data from each pull-down/LC/MS replicate (HAPRO11 and HAPRO11eGFP (MS1-3) or FLAGSmMOB3 and SmMOB3eGFP (MS1-3)) was evaluated with the Proteome Discoverer™ according to the criteria mentioned in Materials and Methods, section 1.6.11.4. In a previous study, pull-downs with the TAP-tagged SLMAP ortholog PRO45 and LC/MS analysis PRO11, SmMOB3 and SCI1 were enriched with very high sum of spectral counts (Nordzieke *et al.*, 2015). Both studies indicate, that SCI1 might be an uncharacterized SmSTRIPAK complex component. In addition, proteins connected to vesicular transport, kinases, a nucleoporin and a small GTPase of the Ras family were identified. However, comparison of enriched proteins identified, SCI1 as most promising potential interaction partner of PRO11. Therefore, the function of SCI1 was analyzed in detail (Table S 1, Table S 2, Table S 3).

### 3.2 SCI1 is a small protein containing coiled-coil domains

Up to now, no *sci* gene was described or investigated in filamentous fungi. In *S. macrospora*, *sci1* with the locus tag SMAC\_05559 encodes a protein comprising 298 AAs (Figure S 5, Figure 9). Beside the four coiled-coil (CC) domains no other domain could be predicted for SCI1 (Figure 9). A CC domain is characterized by a repetitive heptade pattern (HPPHPPP)<sub>n</sub>, where H represents a hydrophobic amino acid and P represents a polar amino acid. Coiled-coils are amphiphilic  $\alpha$ -helices interacting with each other through hydrophobic interactions between the helices (Crick, 1952). They can act as spacer between functional domains but can also mediate protein-protein interactions (Crick, 1952, Munro, 2011, Surkont & Pereira-Leal, 2015, Zhang *et al.*, 2009). Small proteins containing CC domains are associated with the STRIPAK complex (Table 1) but it is not known if they mediate protein interactions.

The human STRIPAK complex associates mutually exclusively with either CTTNBP2 or with SLMAP and the CC-domain containing proteins SIKE and FGFR1OP2 (Goudreault *et al.*, 2009). However, it is not known if CTTNBP2 orthologs exist in fungi. SIKE is assumed to be involved in the systemic response against infection and FGFR1OP2 seems to be required in wound healing, which involves cell fusion (Huang *et al.*, 2005a, Lin *et al.*, 2010). The small CC proteins FGOP2 in *D. melanogaster* and Csc4 in *S. pombe* are described as STRIPAK complex components, but are neither intensively studied in the fruit fly nor in fission yeast (Ribeiro *et al.*, 2010, Singh *et al.*, 2011). The CC proteins,

## Discussion

Far3 and Far7 of *S. cerevisiae* were shown to be required for the pheromone-mediated G1 arrest (Kemp & Sprague, 2003, Lai *et al.*, 2011, Pracheil & Liu, 2013).

SCI1 was identified in PRO11 pull-downs in this study (Figure 8, Table S 1) and was also previously enriched in PRO45 (SLMAP ortholog) pull-downs (Nordzieke *et al.*, 2015) indicating that SCI1 is a STRIPAK complex component in *S. macrospora*. All described small CC proteins associated with the STRIPAK contain one to four CC domains but are barely conserved by sequence (Figure 9, Figure 10). Therefore, BLAST searches cannot be applied to identify the small CC proteins, which are associated with the STRIPAK complex between distantly related species. However, phylogenetic analysis showed that STRIPAK-complex associated small CC proteins are conserved within the phyla. Vertebrates contain FGFR1OP2- and SIKE-like proteins, invertebrates contain FGOP2-like proteins, yeasts contain Far3/7- and Csc4-like proteins and filamentous fungi contain SCI-like proteins (Figure 10).

The number of predicted CC domains and the length of the proteins vary between species indicating that these proteins and the STRIPAK complex might fulfill diverse functions in the respective organisms. In filamentous Ascomycetes such as *S. macrospora*, *N. crassa*, *P. anserina*, *C. thermophilum*, *V. dahliae*, *M. oryzae*, *A. nidulans*, and *A. fumigatus* SCI-like proteins are conserved by sequence but were not yet investigated (Figure 11).

### 3.3 Deletion of *sci1* causes sterility and prevents hyphal fusion in *S. macrospora*

The *S. macrospora* wt reproduces via sexually formed ascospores (Lord & Read, 2011, Pöggeler *et al.*, 1997) and loss of *sci1* leads to a sterile strain unable to produce pigmented protoperithecia and perithecia as well as ascospores (Figure 14 A). Also, no hyphal fusion was detected in  $\Delta sci1_{hyg}$  and protoperithecia formation was highly reduced (Figure 14 B and C). The phenotype of the  $\Delta sci1_{hyg}$  strain is similar to other *S. macrospora* SmSTRIPAK complex mutants ( $\Delta pro11$ ,  $\Delta pro22$ ,  $\Delta Smmob3$ ,  $\Delta Smpp2ac1$  and  $\Delta pro45$ ), which are also sterile and hyphal fusion defective (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004). Similarly, deletion of STRIPAK complex genes *ham-2*, *ham-3*, *ham-4*, *mob-3* and *ppg1* (*pp2Ac*) in *N. crassa* results in hyphal fusion defective strains, which are female sterile and unable to form protoperithecia (Fu *et al.*, 2011, Maerz *et al.*, 2009, Simonin *et al.*, 2010, Xiang *et al.*, 2002). In other filamentous fungi, such as *A. nidulans*, *F. verticillioides*, *F. graminearum*,

## Discussion

*F. virguliforme*, *C. graminicola*, and *E. festucae* STRIPAK complex components are required for hyphal fusion, mycelium growth, sexual development and additionally virulence or symbiotic interaction (Shim *et al.*, 2006, Wang *et al.*, 2010, Green *et al.*, 2016, Wang *et al.*, 2016, Islam *et al.*, 2017, Zhang *et al.*, 2017).

However, a fusion competent *S. macrospora* strain can fuse to the  $\Delta sci1_{hyg}$  fusion-defective strain (Figure 14 D) which might indicate that recognition, fusion or both do not necessarily require regulated cell communication of the fusion partners. In *N. crassa*, fusion of hyphae happens as follows: hyphae make contact, extension of the hyphal tip stops, material required for adhesion is secreted, adhering hyphae swell, the cell wall and adhesive material is removed, both plasma membranes make contact and the fusion pore is formed (Hickey *et al.*, 2002). The fact that extension of  $\Delta sci1_{hyg}$  hyphae does not stop upon contact with other hyphae but wt hyphae can fuse to  $\Delta sci1_{hyg}$  hyphae it is tempting to speculate that deletion of *sci1* might affect secretion from *S. macrospora* hyphae. Thus,  $\Delta sci1_{hyg}$  hyphae might not recognize each other and are unable to attach to each other or both. However, it remains a very interesting task for the future to test secretion in  $\Delta sci1_{hyg}$  compared to the wt.

In addition, vegetative growth in filamentous fungi is connected to exocytosis and vesicular transport (Bartnicki-Garcia, 2002, Steinberg, 2007a) and LC/MS analyses of PRO11, SmMOB3 and SCI1 pull-downs, identified proteins related to transport (Table S 1, Table S 2, Table S 3, Table S 4). Similarly to  $\Delta pro11$  (Bernhards, 2010) the  $\Delta sci1_{hyg}$  strain is highly reduced in vegetative growth (Figure 15 A) which is also true for  $\Delta sci1_{hyg}\Delta pro11$  (Figure 15 B). Thus, the strongly reduced growth rate of the *sci1* deletion background might indicate impaired vesicular transport (section 3.9 and 3.9.2).

Growth test of  $\Delta sci1_{hyg}$  in presence of several stresses were performed to further investigate the *sci1* deletion phenotype. Growth of  $\Delta sci1_{hyg}$  was compared to the wt, *pro11*,  $\Delta pro11$  and the complemented strain  $\Delta sci1_{hyg}::5'sci1egfp$ . Although, deletion of striatin orthologous genes were reported to be sensitive to high glucose levels and CFW induced cell wall integrity stress, all strains tested in this study were reduced in presence of high sugar levels and CFW compared to growth on SWG (Beier *et al.*, 2016, Son & Osmani, 2009) (Figure S 8). In contrast, presence of oxidative stress ( $H_2O_2$ ), nitrogen starvation and presence of high  $CaCl_2$  levels slightly increased growth of  $\Delta sci1_{hyg}$  (Figure S 8). Nitrogen starvation in yeasts and *S. macrospora* induces autophagy, therefore it can be speculated that induction of autophagy might be negatively influenced in the  $\Delta sci1_{hyg}$

strain (Takeshige *et al.*, 1992, Voigt & Pöggeler, 2013, Werner *et al.*, 2016). Additionally, improved growth of the *sci1* deletion strain in presence of high CaCl<sub>2</sub> levels might indicate that calcium supply or a calcium mediated process required for hyphal tip growth might be disturbed (Kim *et al.*, 2012, Silverman-Gavrila & Lew, 2001, Takeshita *et al.*, 2017). In *A. nidulans*, Ca<sup>2+</sup> causes depolymerization of actin and subsequently fusion of accumulated secretory vesicles with the plasma membrane. Therefore, it tempting to speculate that *sci1* deletion might cause a defect in transport of secretory vesicles, exocytosis or both.

### 3.4 *sci1* is up-regulated during sexual development

In *S. macrospora*, cell differentiation, cell wall modulation and formation of three-dimensional fruiting bodies requires tight regulation involving the genes of the SmSTRIPAK complex (Teichert *et al.*, 2014). The *pro11* deletion strain produces rudimentary ascogonia and strains without *pro22*, *pro45*, *Smpp2Ac1*, and *sci1* genes only generate unpigmented protoperithecia, whereas pigmented protoperithecia are formed in the *Smmob3* deletion mutant. This indicates that SmMOB3 is involved in protoperithecia to perithecium transition (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004). Genes encoding the SmSTRIPAK complex components *pro11* and *Smmob3* were shown to be upregulated during sexual development (Bernhards, 2010, Bernhards & Pöggeler, 2011).

Consistent with the transcript level reported in quantitative reverse-transcription PCR experiments for *pro11* (Bernhards & Pöggeler, 2011), the transcript level of *sci1* was very high at day 3 indicating that *sci1* and *pro11* might regulate similar developmental stages. The *sci1* gene was down-regulated at day 4, the time point when *pro22* became up-regulated (Bloemendal *et al.*, 2010) and was up-regulated again at day 5, 6 and 7. Interestingly, the *Smmob3* transcript level was highest at later developmental stages especially at day 6, which corresponds to the *Smmob3* deletion mutant phenotype impaired in later developmental stages (Bernhards & Pöggeler, 2011).

Transcriptional regulation of *sci1*, *pro11*, *pro22* and *Smmob3* might ensure that SmSTRIPAK genes are induced or suppressed at specific time points of the life cycle to initiate and regulate sexual development. Interestingly, MOB3 proteins are conserved among animals and filamentous fungi, which are multicellular organisms and undergo complex cell differentiation but not in yeasts, which are unicellular organisms (Lisa-Santamaría *et al.*, 2012, Pracheil & Liu, 2013, Singh *et al.*, 2011).

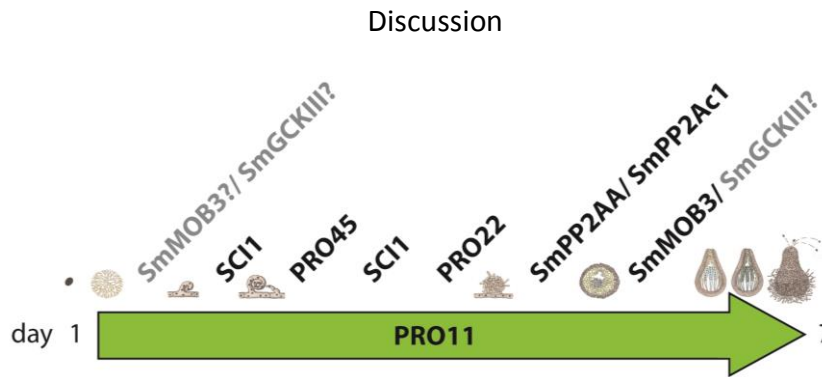

## Discussion

Thus, it is tempting to speculate that the SmSTRIPAK complex controls early developmental processes through PRO11 and SCI1 and is involved in later developmental processes through the association with PRO22 and PP2A and in protoperithecium to perithecium transition by SmMOB3. The STRIPAK complex in *S. macrospora* seems to be very dynamic, regulating several pathways through the association and exchange of interaction partners at given time points of the life cycle. Similarly, the Far complex components interact in a chronological order in *S. cerevisiae*. The Far3 and Far7 proteins interact with the striatin ortholog Far8. Then, the Far3/7/8 complex connects the SLMAP orthologs Far9/10, which are localized to the ER via their TM domains, to the STRIP1/2 ortholog Far11 (Pracheil & Liu, 2013). In mammals, mutually exclusive STRIPAK complexes were suggested but no sequential order of interaction has been described to date (Goudreault *et al.*, 2009).

In *S. macrospora*, the phenotypes of SmSTRIPAK complex deletion mutants, pull-down of SmSTRIPAK proteins and transcript levels of SmSTRIPAK genes suggest a regulation of the SmSTRIPAK complex through its different components during sexual development (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015). SmSTRIPAK complex components might also interact before the SmSTRIPAK complex is regulated through GCKIII kinases by phosphorylation or through the phosphatase SmPP2A by dephosphorylation events. Alternatively, the SmSTRIPAK complex itself might regulate signaling by phosphorylation/ dephosphorylation of target proteins.

Figure 24 summarizes the importance of the SmSTRIPAK complex, through the interaction of the central protein PRO11 with other SmSTRIPAK complex components, during the life cycle of *S. macrospora*. The figure does not exclude several proteins to interact at the same time but shows necessity of the SmSTRIPAK components during the life cycle of *S. macrospora*.

Unfortunately, using conventional RNA isolation, it is not possible to investigate transcript levels of very young, one and two days old mycelium of *S. macrospora* because sufficient amounts of mycelium for RNA isolation are generated from day 3 to 7. To overcome this problem in future, laser microdissection (LM) and RNA-seq might be applied (Teichert *et al.*, 2012).

**Figure 24: Speculative representation of SmSTRIPAK proteins required during the life cycle of *S. macrospora***

*S. macrospora* germinal center III kinase(s) and SmMOB3 might associate with PRO11 during vegetative growth. PRO45 and SCI1 interact with PRO11 in early developmental stages, followed by PRO22. SmPP2AA and SmPP2Ac1 might be required before transition from unpigmented to pigmented protoperithecia. Finally, SmMOB3 and possibly SmGCKIII mediate transition of protoperithecia to mature fruiting bodies. Very early (day 1-2) and late developmental stages (later than day 7) are not investigated and are therefore colored in gray.

### 3.5 The central region of SCI1 oligomerizes and interacts with PRO11

Small CC proteins associate with the STRIPAK in other organisms (Table 1). Consistent with the findings in animals and yeasts, a direct interaction of SCI1 and PRO11 could be shown by Y2H experiments. The N-terminal region of PRO11, between the predicted CaM-binding site and the WD-repeats, is required for the interaction with SCI1 (Figure 25). Interestingly, the region of PRO11 which is required for interaction with PRO22 overlaps with the region required for interaction with SCI1 (Bloemendal *et al.*, 2012). Thus, SCI1 and PRO22 might compete for the interaction with PRO11 or many SmSTRIPAK complex proteins associate to form a supercomplex in which PRO11 oligomerizes (Bloemendal *et al.*, 2012).

Like Far3, SCI1 oligomerizes via its central region (Lai *et al.*, 2011). Furthermore, the central region of SCI1 spanning AA 63-207 was sufficient to partially complement the *sci1* deletion phenotype (Figure 17). Thus, showing that the central region of SCI1, which is also required for interaction with PRO11, is essential for its function in fruiting-body development in *S. macrospora* (Figure 17). Additionally, the N-terminal region of SCI1 interacts with the SmSTRIPAK complex component PRO45 in Y2H experiments without the need of the PRO45 TM domain (Figure 16).

However, PRO11 and PRO45 did not directly interact in Y2H experiments (pers. comm. Steffen Nordzieke), which was confirmed in this study. In sum, SCI1 interacts with the known SmSTRIPAK

## Discussion

complex components PRO11 and PRO45 in Y2H experiments (Figure 25) and might mediate or stabilize the interaction of PRO11 and PRO45. However, it remains a task for the future to define which region of PRO45 is required for interaction with SCI1.

**Figure 25: Interactions sites required for SCI1-PRO11, SCI1-SCI1 and SCI1-PRO45 interaction**

Y2H experiments with PRO11 and SCI1 fragments demonstrated that the N-terminal region of PRO11 is required for interaction with the central region of SCI1. The N-terminal region of SCI1 is required for interaction with PRO45. Position of AAs is given in numbers. Coiled-coil regions of SCI1, PRO11 and PRO45 are indicated in green. The predicted calmodulin-binding site of PRO11 is indicated in yellow and the WD-repeats are presented in purple. The forkhead-associated domain and the transmembrane domain of PRO45 are presented in black and orange, respectively.

### 3.6 Functional conservation of STRIPAK complex-associated proteins containing coiled-coil domains

Pracheil and Liu (2013) assumed that the CC proteins SIKE/FGFR1OP2, Far3 and Far7 and Csc4 have the same structural role in the STRIPAK complex of different species. Also in *S. macrospora*, SCI1, a small CC protein, associated with the SmSTRIPAK complex. Although small CC proteins seem to have the same function in the STRIPAK complex of animals and fungi, mammalian *FGFR1OP2* or yeast *FAR3* and *FAR7* could not complement the sterile phenotype of the *S. macrospora*  $\Delta sci$  strain (data not shown).

In Y2H experiments of this study, the central region of SCI1 with the second and third CC domains was shown to be required for interaction with the yeast Far3 protein. Whereas for interaction with Far7 the N-terminal region of SCI1 was required (Figure 19). Consistently, in *S. cerevisiae*, the Far3

protein self-interacts through its central region and its C-terminal CC domain and Far3 and Far7 interact with each other without the presence of other Far complex components (Lai *et al.*, 2011, Pracheil & Liu, 2013).

Yeast strains with the central region of SCI1 but not with the full-length SCI1 grew better in presence of Far3 (Figure 19). The N-terminal and C-terminal region of SCI1 might hamper interaction with Far3 because the protein is bigger than Far3, limiting accessibility of the interaction site for Far3. However, SCI1 did not interact with the yeast striatin ortholog Far8, which might be caused by low sequence similarity of Far8 and PRO11. Far8, in which the WD region is missing might also adopt a different conformation than PRO11 (Goudreault *et al.*, 2009).

SCI1 oligomerization and interaction of SCI1 with Far3 and Far7 via Y2H indicate a functional conservation for STRIPAK-complex associated small CC proteins, in *S. cerevisiae* and *S. macrospora*. Nevertheless, *S. macrospora* is a multicellular organism undergoing tightly regulated differentiation processes (Pöggeler *et al.*, 2006, Teichert *et al.*, 2014) whereas *S. cerevisiae* is a unicellular organism. Therefore, STRIPAK-complex regulation or function in *S. macrospora* is most likely more complex than in baker's yeast and *FAR3* and *FAR7* cannot compensate for the loss of *sci1*. Similarly, attempts to complement the sterile  $\Delta$ Smmob3 strain with a mouse *Mob3* (*phocein*) construct failed, most likely because of the low level of homology between the mammalian and the fungal *Mob3* (*phocein*) gene (Bernhards & Pöggeler, 2011).

Protein size and also number of small CC domain containing proteins associated with the STRIPAK complex is different in mammals, yeast and filamentous fungi (Figure 9). Regulation of gene expression, folding of the protein, protein modification and conformation of interaction sites and interaction with STRIPAK complex orthologs might be different between distantly related species.

### **3.7 SCI1 is part of the core SmSTRIPAK complex in *S. macrospora***

In mammals, the core STRIPAK complex consist of striatin, PP2A with its scaffolding and the catalytic subunit, STRIP1/2, SLMAP, and the CC domain proteins SIKE/FGFR1OP2. GCKIII kinases MST4/STK24/STK25 and the kinase activator MOB3 (*phocein*) associate with the core STRIPAK complex in animals and filamentous fungi (Goudreault *et al.*, 2009) (Table 1). Similarly, of in *D. melanogaster*, the core STRIPAK complex component: Cka (striatin), Pp2A-29B (PP2AA) and Mts (PP2Ac1), the STRIP1/2 ortholog CG11526, the SLMAP ortholog CG17494, GCKIII kinases and the

## Discussion

kinase activator Mob4 are found (Ashton-Beaucage *et al.*, 2014, Ribeiro *et al.*, 2010). CG17494 (SLMAP) was identified with *in silico* analysis and is highly expressed during embryonal development but was not shown to interact with other dSTRIPAK complex components (Ribeiro *et al.*, 2010). However, depletion of CG17494 (SLMAP) or other dSTRIPAK components suppresses activation of the dJnk pathway controlling epithelial sheet movement and dorsal closure in *Drosophila* embryos suggesting that the SLMAP ortholog CG17494 acts together with Cka, Mob4 and the STRIP1/2 ortholog CG11526 (Ashton-Beaucage *et al.*, 2014, Ribeiro *et al.*, 2010). In yeasts, no kinase activator was identified but Far3 and Far7/Csc4, Far8/Csc3 (striatin), Far9/10/Csc1 (SLMAP) and Far11/Csc2 (STRIP1/2) associate in the Far and SIP complex of *S. cerevisiae* and *S. pombe*, respectively (Lai *et al.*, 2011, Lisa-Santamaría *et al.*, 2012, Pracheil & Liu, 2013, Singh *et al.*, 2011).

In *S. macrospora*, the interaction of PRO11 with SCI1, PRO22 and PRO45 resembles the situation in yeasts but additionally SmMOB3 interacts with PRO11 as described for striatin and MOB3 orthologs in animals (Baillat *et al.*, 2001, Bernhards & Pöggeler, 2011, Goudreault *et al.*, 2009, Ribeiro *et al.*, 2010) (Figure 26).

**Figure 26: Schematic representation of the STRIPAK complex in *S. macrospora***

The striatin ortholog PRO11 acts as scaffold to bring SmSTRIPAK complex proteins together. PRO11 interacts with the kinase activator SmMOB3, the SLMAP ortholog PRO45, the STRIP1/2 ortholog PRO22 and with the small coiled-coil protein SCI1. The phosphatase catalytic subunit (SmPP2Ac1) is attached to the SmSTRIPAK via PP2AA and PRO22. SmGCKIII kinases might counteract the phosphatase activity via SmMOB3. Interactions presented are derived from Co-IP, Y2H and pull-down experiments (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015).

### 3.8 SCI1 and PRO11 colocalize at the nuclear envelope

For striatins many possible localizations were described up to date. Csc3 in *S. pombe* associates with early mitotic spindle-pole bodies (SPB) and the Golgi (Frost *et al.*, 2012, Singh *et al.*, 2011).

## Discussion

Far8 and other Far complex components Far9, Far10, Far11 and the two small CC proteins Far3 and Far7 were shown to localize to the ER in *S. cerevisiae* (Pracheil & Liu, 2013). In *S. pombe*, Csc4 was GFP-tagged but could not be localized so far (Singh *et al.*, 2011). In *A. nidulans* and *F. verticillioides*, the striatin orthologs were localized to the nuclear envelope (NE) and the ER (Wang *et al.*, 2010, Zhang *et al.*, 2017). HAM-3 in *N. crassa* was suggested to localize to the NE and punctiform endomembrane system (Dettmann *et al.*, 2013).

This is the first study, showing that a SmSTRIPAK complex-associated small CC protein colocalizes with the striatin ortholog PRO11 at the NE in *S. macrospora* (Figure 20 D). Also, signals for PRO11 and SCI1 fluorescent fusion proteins were detected in the punctiform endomembrane system and filamentous structures sometimes emerging from the nucleus (Figure 20 D, Figure S 12). The nuclear envelope is continuous with the ER (Watson, 1955). Therefore, it is likely that SmSTRIPAK complex proteins associate with the ER, making it difficult to distinguish clearly between NE and ER in fluorescence microscopy because of their close connection. Interestingly, PRO11, SmMOB3 and SCI1 pull-downs coupled to LC/MS identified two putative nucleoporins (SMAC\_02409 and SMAC\_00774), as potential interaction partner of both proteins indicating that SmSTRIPAK complex components might be directly connected to the NE (Table S 1, Table S 3, Table S 4).

However, the STRIPAK complex might also be involved in ER to Golgi transport. Mammalian striatins contain a caveolin-binding domain to interact with caveolin (Gaillard *et al.*, 2001). Cav1 synthesis takes place in the ER and Cav1 is transported to the Golgi (Hayer *et al.*, 2010). Mammalian SG2NA and zinedin interact with Cav1 (Gaillard *et al.*, 2001) indicating a possible role of the STRIPAK complex in ER to Golgi transport. However, filamentous fungi do not encode caveolin orthologs (Nowrousian, 2010, Pöggeler & Kück, 2004). Additionally, in mammalian fibroblast cells, SG2NA was shown to maintain ER homeostasis (Jain *et al.*, 2017).

Recently, SLMAP the ortholog PRO45 of *S. macrospora* was shown to localize to the NE, ER and mitochondria. It was suggested that PRO45 might bridge the NE and the outer mitochondrial membrane for signaling (Nordzieke *et al.*, 2015). However, no alteration of nuclei or mitochondria was observed in the  $\Delta sci1$  strain (Figure S 13). Similarly, the SmSTRIPAK complex of *S. macrospora* might associate to the NE before it is transported to the ER.

### 3.9 SCI1 might be involved in vesicular transport

Current and previous studies demonstrate that  $\Delta sci1$ ,  $\Delta pro11$  and  $\Delta Smpp2ac1$  mutants have a strongly reduced vegetative growth rate (Beier *et al.*, 2016, Bernhards, 2010), which might be caused by impaired transport of endosomes (Peñalva, 2010, Shaw *et al.*, 2011). *In silico* analysis of SmMOB3 indicates a role in vesicular transport (Bernhards & Pöggeler, 2011) and proteins involved in vesicular transport were identified in PRO11 and SmMOB3 pull-downs coupled to LC/MS (Table S 1, Table S 2, Table S 3).

Therefore, endosomal transport of early endosomes (EEs) in the wt and the  $\Delta sci1$  strain was investigated using the N-terminally eGFP-tagged Rab5 protein from the ascomycete *Z. tritici* (Kilaru *et al.*, 2015). The reporter protein eGFPZtRAB5 appeared to accumulate in  $\Delta sci1_{nat}::egfpZtRab5$  hyphae compared to wt::egfpZtRab5. However, EE transport was not disturbed because in  $\Delta sci1_{nat}::egfpZtRab5$  EEs moved along filamentous structures through the hyphae (Video 8). The eGFP protein is very stable and was detected in vacuoles of wt::egfpZtRab5 indicating that the eGFPZtRab5 protein is degraded. However, the lumen of vacuoles in  $\Delta sci1_{nat}::egfpZtRab5$  hyphae was not stained by eGFP (Figure 22 B).

In *S. cerevisiae*, the SLMAP ortholog Far9 directs sorting of proteins to vacuoles in regulating vesicular traffic. Deletion of yeast FAR9 (SLMAP) results in aberrant vacuoles and strongly decreased secretion of the  $\alpha$ -factor (Bonangelino *et al.*, 2002). In the study of Bonangelino *et al.* (2002), the deletion mutant Far9 showed a strong aberrant vacuolar phenotype and the Far 11 deletion mutant (STRIP1/2) showed a weakly aberrant vacuolar phenotype (Bonangelino *et al.*, 2002).

Thus, the lack of free eGFP in  $\Delta sci1_{nat}::egfpZtRab5$  vacuoles might be caused by a vesicle transport defect, nevertheless, movement of EEs was observed in  $\Delta sci1_{nat}::egfpZtRab5$  (Video 8). Additionally, FM4-64 was internalized and stained vacuolar membranes in the wt and in the *sci1* deletion background strains arguing against a complete vesicle to vacuole transport defect in the *sci1* deletion strain (Fischer-Parton *et al.*, 2000, Hoffmann & Mendgen, 1998, Read *et al.*, 1998) (Figure S 15 B).

### 3.9.1 The STRIPAK complex has a role in ER to Golgi transport

In mammals, the STRIPAK complex was connected to ER to Golgi transport (Kean *et al.*, 2011) and striatin, SG2NA, STRIP1/2 and MOB3 localize to the Golgi (Frost *et al.*, 2012). Frost and colleagues (2012) speculated that the STRIPAK complex might be involved in Golgi fragmentation and targeting of Golgi fragments to centrosomes during mitosis.

The Golgi apparatus in mammals is partitioned between dividing cells but has to be fragmented before. The Golgi ribbon is unstacked in G2 phase, which is mediated by several kinases (Acharya *et al.*, 1998, Colanzi *et al.*, 2000, Colanzi *et al.*, 2003, López-Sánchez *et al.*, 2009, Ruan *et al.*, 2004, Shorter & Warren, 2002, Sütterlin *et al.*, 2001). Subsequently, the Golgi proteins GM130 and GRASP65 are phosphorylated and the cell enters mitosis (Hidalgo Carcedo *et al.*, 2004, Sütterlin *et al.*, 2002) (Figure 27 A).

**Figure 27: The Golgi apparatus, vesicle transport and the Golgi checkpoint in mammals**

**A:** Golgi in S-phase appears as ribbons and is fragmented into Golgi stacks before the cell enters Mitosis. Golgi stacks are further fragmented and partitioned between daughter cells. **B:** Schematic representation of ER-Golgi forward- and back-transport of cargoes. ER derived vesicles are transported to the cis-Golgi, vesicles from the cis-Golgi can be targeted to the ER or vesicles are secreted through the trans-Golgi for transport to defined cell sites. Modified according to De Matteis and Luini (2008) and Corda *et al.* (2012).

## Discussion

In mammals, Golgi stacks are further fragmented appearing as a “haze” to be partitioned between the daughter cells (Altan-Bonnet *et al.*, 2004, Colanzi & Corda, 2007, Shorter & Warren, 2002). After partitioning between daughter cells, Golgi fragments are re-stacked to Golgi ribbons via dephosphorylation of the Golgi stacking protein GRASP65 by PP2A, a phosphatase, which is also present in the STRIPAK complex (Tang *et al.*, 2008, Goudreault *et al.*, 2009) (Figure 27 A).

The Golgi apparatus of mammals mediates and controls sorting of cargo (Figure 27 B). Proteins synthesized in the ER pass through the Golgi and are transported to their destinations or endosomes are transported back to the Golgi (De Matteis & Luini, 2008). Final post-translational modification of proteins takes place in the Golgi and lipids are transferred from the ER to the Golgi (De Matteis & Luini, 2008, Ladinsky *et al.*, 1999, Mogelsvang *et al.*, 2004) (Figure 27 B).

Recently, the SmSTRIPAK component SmMOB3 of *S. macrospora* was described to interact with the glycosylphosphatidylinositol-anchored protein 1 (SmGPI1) in Y2H experiments (Frey *et al.*, 2015a). GPIs are synthesized in the ER, pass through the Golgi and are anchored in the plasma membrane (Orlean & Menon, 2007).

In yeasts, the prevacuolar compartment (PVC) mediates protein sorting between the Golgi and vacuoles in an anterograde and retrograde manner. In *S. cerevisiae*, the vacuolar protein sorting-associated protein 27 (Vps27) associates with vesicles and mediates sorting of vesicles to the vacuoles but also ensures return to the Golgi (Piper *et al.*, 1995). The yeast ortholog Vps21 of mammalian Rab5 is required for Golgi exit into the PVC and mutants lacking Vps21 accumulate vacuolar proteins in the PVC hence vacuolar proteins are not delivered to vacuoles (Gerrard *et al.*, 2000).

This study gives first hints, that the SmSTRIPAK complex might regulate vesicular traffic maybe through the Golgi in *S. macrospora*. In the *sci1* deletion background, accumulation of eGFPZtRab5eGFP was detected in big punctiform structures in young hyphae and no free eGFP was detected in vacuoles (Figure 22) suggesting a defect in vesicle to vacuole transport.

In mammals, striatins and CCM3 were shown to regulate MST4 association with Golgi in an opposite manner (Kean *et al.*, 2011). Depletion of striatin might block ER to Golgi transport and depletion of CCM3 might prevent secretion from the Golgi. Taken together, the STRIPAK complex in mammals was connected to ER to Golgi transport and vesicle transport from the Golgi, but up to now no CCM3 ortholog was described in filamentous fungi.

## Discussion

Deletion of *sci1* results in trapping of eGFPZtRab5 in either, the intermediate compartment between ER and Golgi or in the Golgi indicates a possible role of SCI1 as golgin. Golgins are predominantly CC proteins attached to the Golgi via their C-terminal transmembrane domains (TM) or associate via other membrane bound proteins to the Golgi if they lack a TM domain (D'Angelo *et al.*, 2013).

SCI1 contains four predicted CC domains and, like golgins shows no sequence homology (Witkos & Lowe, 2015) with other small CC proteins associated with STRIPAK complexes in other distant related species. However, no transmembrane domain was predicted for SCI1.

Investigation of vesicle transport especially between the ER and Golgi should be performed in *S. macrospora* to dissect how and when the SmSTRIPAK complex might be involved in vesicle transport. In mammalian cells, MOB3 (phocein) was described to function in vesicular traffic. MOB3 (phocein) and SG2NA were localized to the Golgi and treatment with brefeldin A (BFA) caused dispersion of MOB3 (phocein) and SG2NA to the cytosol (Baillat *et al.*, 2001). In *N. crassa* BFA was shown to inhibit ER to Golgi transport of the plasma membrane H<sup>+</sup>-translocating ATPase (PMA-1) and caused accumulation of PMA-1 in subapical and distal hyphal regions (Fajardo-Somera *et al.*, 2013).

Thus, *S. macrospora* strains synthesizing SmSTRIPAK complex proteins fused to fluorophores should be investigated upon treatment with BFA to clarify if the SmSTRIPAK complex is involved in ER to Golgi transport. Looking at vesicular transport borders between the specific compartments might be blurred, because of the continuous exchange and recycling of molecules and membranes within cells. Nothing is known about Golgi morphology in SmSTRIPAK complex deletion mutants of filamentous fungi. Therefore, using reasonable marker proteins might help to clarify at which point the SmSTRIPAK complex might mediate vesicular transport.

### **3.9.2 The STRIPAK complex is connected to microtubules and Golgi inheritance**

In this study, a putative dynein ortholog was enriched in SCI1 pull-downs (Figure 18, Table S 4). Also, in PRO11 pull-downs a putative kinesin ortholog and a putative cencentractin ortholog were identified (Table S 1). Additionally, in PRO11 and SmMOB3 pull-downs a putative myosin-5 ortholog and a putative nucleoporin were found (Table S 3). These data indicate that the *S. macrospora* STRIPAK complex might be connected to vesicle transport and microtubules. Also in this study, SCI1

## Discussion

and PRO11 were colocalized to the NE. In previous studies, PRO22 was shown to localize to tubular vacuoles, which are connected to long distance transport along microtubules in hyphae of filamentous fungi (Bloemendal *et al.*, 2010, Darrah *et al.*, 2006, Hyde *et al.*, 1999).

Recently, the *S. macrospora* STRIPAK complex component PRO45eGFP was localized in the  $\Delta$ pro11 background to defined spots in direct proximity of the nucleus, which were suggested to be SPBs (Nordzieke, 2014). Orthologs of STRIPAK complex components in other organisms were also connected to spindle-pole bodies (SPBs). In contrast to the baker's yeast, *S. pombe* proteins of the septation initiation network (SIN), which is involved in cytokinesis and septation, localize to SPBs (Singh *et al.*, 2011). In *N. crassa*, the kinases STK-3 and STK-24 but no other STRIPAK complex components were localized to the SPBs in vegetative hyphae (Heilig *et al.*, 2014, Heilig *et al.*, 2013). In mammals, microtubule minus ends are located at centrosomes and it was shown that the dynactin/dynein complex is required for transport of Golgi fragments along microtubules (Burkhardt *et al.*, 1997, Corthésy-Theulaz *et al.*, 1992). Close positioning of the Golgi to the nucleus was suggested to coordinate polarization, mitosis and apoptosis (Hicks & Machamer, 2005).

The results of this thesis show that, in  $\Delta$ sci1::egfpZtrab5, large punctiform structures visualized by the EE marker dispersed like clouds around dark regions, most like representing nuclei before punctiform structures reformed (Video 9). However, the Golgi in filamentous fungi does not exist as stacks but as dispersed cisternae (Breakspear *et al.*, 2007, Hubbard & Kaminskyj, 2008, Lee & Shaw, 2008, Suda & Nakano, 2012). If Golgi cisternae in *S. macrospora* can be fragmented and how Golgi inheritance is mediated in *S. macrospora* remains to be determined.

In mammalian cells, the GCKIII kinase STK25 and the GCKII MST1 were found to localize via the *cis*-Golgi protein GM130 to the Golgi and interact with the STRIPAK complex component CCM3 (Preisinger *et al.*, 2004). CCM3 and the GCK kinases are required for Golgi assembly, positioning and cell migration (Fidalgo *et al.*, 2010). The STRIPAK complex components SG2NA, STRIP1 and MOB3 localize to the Golgi and SLMAP is localized to the outer NE or during mitosis to centrosomes and surrounds the mitotic spindle (Baillat *et al.*, 2001, Moreno *et al.*, 2001). MOB3 depletion results in spindle failure (Frost *et al.*, 2012). Thus, it was suggested that SLMAP connects the Golgi, the NE and centrosomes and might be required for Golgi partitioning between daughter cells (Frost *et al.*, 2012, Guzzo *et al.*, 2005, Guzzo *et al.*, 2004a). In *D. melanogaster* the *Mob4* transcript is highly expressed during development of *Drosophila* embryos and enriched in their nervous system.

## Discussion

Interestingly, *Mob4* defects result in abnormal synaptic development, disorganized microtubules and disrupted axonal transport (Schulte *et al.*, 2010).

In *S. macrospora*, the SLMAP ortholog PRO45 was shown to directly interact with PRO11 and SmMOB3 and was localized to the NE, the ER and mitochondria. Also, PRO45 was localized to SPBs in the  $\Delta pro11$  background (Nordzieke *et al.*, 2015) (Figure 28). Thus, it is possible that the interaction between PRO45 and the other core SmSTRIPAK complex components in vegetative hyphae is primarily required to mediate vesicle transfer between the ER, Golgi and microtubules. However, if the SmSTRIPAK complex is involved in Golgi inheritance remains to be investigated.

### Figure 28: The SmSTRIPAK complex might be involved in dynein-mediated transport

Speculative model of Golgi transport along microtubules in *S. macrospora*. Dynein heavy chain was enriched in SCI1eGFP pull-downs coupled to LC/MS and SCI1 and PRO45 directly interact in Y2H experiments. In the *S. macrospora*  $\Delta pro11$  strain, eGFP-tagged PRO45 localized to the spindle-pole bodies. The SmSTRIPAK complex might be required to target the Golgi to the NE or for Golgi inheritance during mitosis. However, it is not known if Golgi cisternae can be fragmented in *S. macrospora*.

### 3.9.3 The SmSTRIPAK complex mediates septation in ascogonia

In *S. pombe*, the SIP complex, which is the ortholog of the STRIPAK complex, negatively regulates SIN to ensure proper septum formation and cytokinesis (Singh *et al.*, 2011). A functional actin ring is required for septum growth and cell-wall synthesis to complete cytokinesis in *S. pombe*. Absence

## Discussion

of actin ring allows septum formation but septae are highly disorganized and non-circular (Zhou *et al.*, 2015). The STRIPAK complex-associated protein CCM3 of *Caenorhabditis elegans* functions in cytokinesis, Golgi stability, localization of cell-surface proteins and is involved in actin organization (Lant *et al.*, 2015, Pal *et al.*, 2017).

In *S. macrospora*, *Smpp2Ac1* and *pro22* deletion strains and in the *pro22* mutant, no intercalated septae were detected in ascogonia (Beier *et al.*, 2016, Bloemendal *et al.*, 2010). Therefore, a dysregulation of the SIN was suggested in  $\Delta$ *pro22* and  $\Delta$ *Smpp2Ac1* strains (Beier *et al.*, 2016). Although *PRO22*, *SmPP2Ac1*, *PRO11* and *SCI1* are SmSTRIPAK complex components intercalating septae were present in ascogonia of  $\Delta$ *sci1*,  $\Delta$ *pro11* and the *pro11* mutant. Also actin polymerization in the vegetative hyphae of the wt and  $\Delta$ *sci1* background was similar (Figure 21, Video 5, Video 6). However, it cannot be excluded that polymerization of actin in septae of ascogonia might be different from actin polymerization in septae of vegetative hyphae. Therefore, actin polymerization should also be studied in ascogonia of SmSTRIPAK complex deletion mutants in the future.

Septae in fruiting bodies of filamentous fungi show a different morphology than in vegetative hyphae. In *Sordaria humana*, septae in walls of croziers show intense annular swelling of septal pores. Also many layers of cisternae were shown to be deposited on both sites of the septal pore (Beckett, 1981). In ascogonous hyphae of *S. macrospora* swollen dense rings were observed at the edge of septal pores. Tubular cisternae were closely associated with the dense rings radiating into the cytoplasm between two cells (Beckett Alan, 1974). However, nothing is known about septal-pore ultrastructure in ascogonia of SmSTRIPAK complex deletion mutants. Septal pores of *S. macrospora* are not closed in vegetative hyphae. However, ascogonous hyphae might be plugged by accumulation of ER and Golgi cisternae to separate two nuclei for karyogamy in one cell. However, such a plug would still allow vesicle transport. A disturbed exchange of vesicles between vegetative hyphae and the protoperithecium or between cells within the developing fruiting body might block perithecium formation because nutrients, enzymes and membrane supply is insufficient or blocked. Also, specialized cells in protoperithecia might be tightly interconnected to ensure nutrition and development of ascospores. It will be very interesting to investigate ER and Golgi ultrastructure in septal pores of SmSTRIPAK complex deletion mutants in comparison to wt septal pores.

### 3.9.4 The STRIPAK complex might be involved in autophagy

Autophagy takes place in eukaryotes to degrade and recycle cytoplasm for reuse, especially during stress conditions like starvation. The double membrane phagophore sequesters the cargo, expands and elongates and forms the autophagosome. The autophagosome outer membrane fuses with a vacuole and the autophagic body (inner membrane) is released into vacuoles for degradation. Every membrane source in the cell can contribute to autophagosome formation (Feng *et al.*, 2014). In *S. cerevisiae*, proteins associated with the late and early Golgi were shown to be involved in phagophore extension and thus the generation of the autophagosome. ADP ribosylation factors (Arf) GTPases were considered to be most important for Golgi vesicle formation in the baker's yeast and in mammals (Nie *et al.*, 2003, van der Vaart *et al.*, 2010). However, in mammals formation of the vesicles was not required for autophagosome formation but for maturation of the autophagosome by fusion with EEs (Razi *et al.*, 2009). In this study, accumulation of the EE marker eGFPZtRab5 was detected in the *sci1* deletion strain and no eGFP signal was present in large vacuoles indicating a possible defect in autophagy (Figure 22). As the STRIPAK complex in *S. macrospora* might be connected to the Golgi or ER, it might also be connect to autophagosome formation.

In mammals, Rab5 together with Beclin1 and vacuolar sorting protein 34 (VPS34) regulates autophagosome formation, which is decreased when Rab5 is inhibited (Ao *et al.*, 2014, Ravikumar *et al.*, 2008). Additionally, mammalian TOR kinase activity inhibits activity or expression of Atg proteins (Jung *et al.*, 2010) and Rab5 together with Beclin1 and VPS 34 counteracts mTOR kinase activity to promote autophagosome formation (Simonsen & Tooze, 2009). Interestingly, in *S. cerevisiae* the Far complex was connected to TORC1/2 signaling and in *S. macrospora* proteins of the TORC signaling pathway were pulled-down with SmPP2Ac1 (Baryshnikova *et al.*, 2010, Beier *et al.*, 2016, Lisa-Santamaría *et al.*, 2012, Pracheil *et al.*, 2012). Thus, the SmSTRIPAK complex might regulate autophagosome formation trough TORC signaling. As in *S. cerevisiae*, SmTORC might be negatively regulated by the SmSTRIPAK. In consequence a non-functional or a lack of SmSTRIPAK complex components could influence autophagosome formation interfering with the autophagy process.

In *S. macrospora*, fruiting bodies are highly complex structures that arise from two dimensional mycelium and fruiting-body development is coupled to cell death. Deletions of genes encoding

## Discussion

proteins associated with autophagy show reduced vegetative growth and are sterile, which was also described for strains lacking SmSTRIPAK complex genes (Beier *et al.*, 2016, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordziede *et al.*, 2015, Pöggeler & Kück, 2004, Voigt & Pöggeler, 2013, Werner *et al.*, 2016).

Recently, the striatin ortholog Cka of *D. melanogaster* was connected to autophagosome transport in neurons via direct interaction of Cka with dynein and Atg8. Depletion of Cka caused accumulation at terminal boutons and depletion of the Hpo kinase decreased autophagic vesicles in terminal boutons. Also, Cka, MOB4 and STRIP were shown to regulate transport of autophagic vesicles and dense-core vesicles (DCV) (Neisch *et al.*, 2017). The authors conclude that Cka interacts with both, the phosphatase and the kinase to regulate axonal transport of DCVs and autophagic vesicles.

In *S. macrospora*, vesicles containing eGFPZtRab7 are delivered to the vacuoles in both strains wt:egfpZtrab7 and  $\Delta$ sci1:egfpZtrab7 because eGFP signals were detected inside vacuoles and at the vacuolar membrane (Figure 23 C, D and E). However, tubular structures in young hyphae of  $\Delta$ sci1 appeared shorter and scattered compared to the wt (Figure 23 A and B). Microtubules determine vacuolar morphology and motility (Hyde *et al.*, 1999). Thus, vacuolar transport along microtubules or the connection between vacuoles and microtubules might be disturbed in the  $\Delta$ sci1 background compared to wt hyphae. Tubular vacuoles mediate longitudinal transport over millimeters to centimeters within the hyphae (Darrah *et al.*, 2006) and disturbed transport along microtubules in  $\Delta$ sci1 might also explain the reduced vegetative growth phenotype.

In mammals, Rab7 is involved in autophagosome to vacuole/lysosome fusion (Gutierrez *et al.*, 2004, Hyttinen *et al.*, 2013, Jäger *et al.*, 2004, Vanlandingham & Ceresa, 2009). Therefore, it is of great interest to investigate phagophore extension and fusion of autophagosomes with vacuolar membranes in  $\Delta$ sci1 compared to wt. Localization of an autophagy marker, for example SmATG8 (Voigt & Pöggeler, 2013, Werner *et al.*, 2016) and simultaneous localization with eGFPZtRab5 or eGFPZtRab7 in *S. macrospora* might help to clarify if autophagy is disturbed in SmSTRIPAK complex deletion mutants.

The fusion defect observed in SmSTRIPAK complex deletion mutants might be explained by the inability to reuse molecules and membranes, to normally deliver or transport certain components to the endomembrane system and to specific locations at the membrane. Break down and reuse of cell walls might be reduced and the fusion partner might not be sensed because certain molecules cannot be secreted. Rapid hyphal tip growth requires microtubules (Horio & Oakley,

2005) and also endocytic recycling is connected to hyphal growth (Peñalva, 2010, Shaw *et al.*, 2011). However, nothing is known about morphology of microtubules and endocytic recycling in *S. macrospora* STRIPAK complex mutants and needs to be investigated in the future.

### 3.9.5 Vacuolar morphology is altered in $\Delta$ sci1<sub>nat</sub>

In this study, the LE marker Rab7 from *Z. tritici* was used to investigate the behavior of LEs in the wt::eGFPZtRab7 and in the  $\Delta$ sci1<sub>nat</sub>::eGFPZtRab7 strain. Vesicles were observed fusing with tubular structures followed by spherical vacuoles and vacuoles elongating, splitting and fusing (Figure 23, Video 11). A similar sequence of stained organelles was reported in *N. crassa*. The vacuolar Ca<sup>2+</sup> ATPase NCA-2 and the vacuolar protein VAM-3 were localized to tubular vacuoles in young hyphae, small vesicles and in more distal hyphal regions in large spherical vacuoles (Bowman *et al.*, 2009). However, the tubular structures in the  $\Delta$ sci1 background were shorter than in the wt background and vacuoles were also observed in young hyphae. Additionally, large vacuoles without free eGFP were frequently detected in  $\Delta$ sci1<sub>nat</sub>::eGFPZtRab7 but in the wt background they appeared to be smaller and were only found in very distal hyphal regions (Figure 23 D). In plants, two types of vacuoles were described. Acidic vacuoles were intensively stained with CMAC whereas storage vacuoles were weakly stained (Swanson *et al.*, 1998). In both strains, wt:egfpZtrab7 and  $\Delta$ sci1<sub>nat</sub>:egfpZtrab7, vacuoles with free eGFP and without eGFP signal as well as intermediates were detected (Figure 23 C, D and E). The LE marker protein eGFPZtRab7 stained the vacuolar membranes of both strains indicating that LE to vacuole fusion is not impaired. Thus, it has to be considered, that the fluorescent protein GFP might be quenched in acidic pH (Bowman & Bowman, 2010, Enoki *et al.*, 2004). Therefore, roundish structures without an eGFP signal and brightly stained with CMAC in  $\Delta$ sci1<sub>nat</sub>:egfpZtrab7 might be acidic vacuoles (Figure 23 E, Figure S 15 B). Accumulation of acidic vacuoles in  $\Delta$ sci1<sub>nat</sub> might indicate a defect in reuse of degraded material, more specific in transport of degraded material from vacuoles to a cargo-sorting compartment, hence in secretion. Similar, in *S. cerevisiae* deletion of yeast FAR9 (SLMAP) results in aberrant vacuoles and strongly decreased secretion of the  $\alpha$ -factor (Bonangelino *et al.*, 2002).

Vacuoles, the ER, mitochondria and the Golgi are Ca<sup>2+</sup> reservoirs (Jackson & Heath, 1993). Calcium level in hyphae of filamentous fungi is highest at the hyphal tip and Ca<sup>2+</sup> changes in a pulsatile manner are required for hyphal tip growth (Kim *et al.*, 2012). In *N. crassa*, the Ca<sup>2+</sup> pumping ATPase

NCA-1 localized to the NE, which was considered as specialized region of the ER (Newport & Forbes, 1987, Prinz *et al.*, 2000, Wedlich-Söldner *et al.*, 2002). Calcium pumping ATPases were also localized to small vesicles and to lysosome-like compartments (Gerasimenko & Tepikin, 2005). Interestingly, vesicular and vacuolar structures described by investigation of NCAs in *N. crassa* were similarly visualized in this study with the eGFPZtRab7 reporter construct, and were altered in the *sci1* deletion mutant background (Figure 23).

In mammals, striatins interact with calmodulin (CaM) in a  $\text{Ca}^{2+}$ -dependent manner but it is not known if this is also true for PRO11 in *S. macrospora* (Castets *et al.*, 1996, Castets *et al.*, 2000, Moreno *et al.*, 2000, Bartoli *et al.*, 1998). However, the C-terminally eGFP-tagged PRO22 protein localizes to tubular vacuoles, a potential  $\text{Ca}^{2+}$  reservoir. In contrast to PRO22, the eGFP-tagged HAM-2 was detected at the NE (Dettmann *et al.*, 2013). Also, the striatin ortholog PRO11 localizes to the NE and interacts with PRO22 (Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Gerasimenko & Tepikin, 2005). Localization of HAPRO11eGFP in the *pro11* deletion background and SCI1DsRED in the *sci1* deletion background showed that both fusion proteins localize to tubular structures (Figure S 17 B and C). However, if PRO11 signals in a  $\text{Ca}^{2+}$ -dependent manner via CaM remains to be investigated.

Localization of eGFPZtRab7 in *S. macrospora* suggests a highly interconnected long distance transport from young hyphae to old hyphae, maybe also in an anterograde manner. Whether calcium signaling and transport from ER to vacuoles, from vacuoles to ER, or vacuolar transport is mediated by the STRIPAK complex in *S. macrospora* remains to be determined.

### **3.9.6 SCI1 and PRO11 connect the SmSTRIPAK complex to vesicular transport and microtubules**

Microtubules are required for transport of vesicles through the cytoplasm and dynein or kinesin association mediates the direction (Lu & Gelfand, 2017). In *D. melanogaster*, the ortholog of STRIP1/2, Strip regulates dendrite branching and axon elongation of olfactory projection neurons and is suggested to be involved in microtubule organization. The *D. melanogaster* protein Strip forms a complex with Glued, an ortholog of mammalian p150, at growing ends of microtubules. Therefore, it was suggested that the dSTRIPAK complex together with Glued mediates transport from actin to microtubules (Sakuma *et al.*, 2014). Depletion of the MOB3 ortholog Mob4 was

## Discussion

connected to abnormal budding events from cellular compartments and a Mob4 mutant shows defects in axonal transport and microtubule organization (Schulte *et al.*, 2010).

In mammals, striatin was connected to dynein (Goudreault *et al.*, 2009). In this study, a putative dynein heavy chain ortholog was identified in SCI1 pull-downs. Furthermore, putative orthologs of proteins associated with vacuolar transport (SMAC\_04234 and SMAC\_08299), transport from ER to Golgi (SMAC\_06397), ER/NE (SMAC\_00774) and secretion from *trans*-Golgi were identified (SMAC\_03125) (Figure 18, Figure S 10, Table S 1, Table S 4).

Accumulation of the EE marker eGFPZtRab5 and the more scattered appearance of presumably tubular vacuoles visualized by the LE marker eGFPZtRab7 in young hyphae of  $\Delta sci1::egfpZtrab5$  and  $\Delta sci1::egfpZtrab7$ , respectively, indicates vesicle and vacuolar transport defects in the  $\Delta sci1$  background. Taken together, the results of this thesis indicate that SCI1 might be required for long distance transport of vesicles or transfer of vesicles to microtubules, but the cargo could not be identified.

Vesicle transport also involves actin polymerization. Actin was observed at fusion sites of conidial anastomosis tubes of *N. crassa* and it was suggested that actin patches and cables are required for endo- and exocytosis (Berepiki *et al.*, 2010). Secretory vesicles in *A. nidulans* are loaded with kinesin, dynein and the myosin-5 ortholog MyoE (Pantazopoulou *et al.*, 2014, Peñalva *et al.*, 2017). Transport along actin fibers and actin polymerization should be investigated at the site of fusing hyphae and particularly of fusion between wt and  $\Delta sci1$  hyphae. Especially, because a putative myosin-5 ortholog (SMAC\_05008) was identified in PRO11 and SmMOB3 pull-downs, as well as a putative kinesin ortholog (SMAC\_04212) and a putative actin-2 protein (SMAC\_07827) in PRO11 pull-downs. Also, dynein heavy chain (SMAC\_00761) was enriched in SCI1 pull-downs coupled to LC/MS (Figure 18, Table S 1, Table S 2, Table S 3, Table S 4).

Therefore, the STRIPAK complex of filamentous fungi might be directly involved in vesicle transport over long distance as well as in short distance transport requiring actin fibers and myosin to ensure proper material exchange at the fusion sites or between organelles (Figure 29).

## Discussion

**Figure 29: The STRIPAK complex in *S. macrospora* might be involved in long and short distance transport of vesicles**

Speculative representation of the STRIPAK-complex function in *S. macrospora*. In PRO11, SmMOB3 and SCI1 pull-downs coupled to LC/MS putative orthologs of a kinesin, dynein and a myosin protein were identified. The SmSTRIPAK complex component PRO22 localizes to tubular vacuoles implicated in long distance transport but the SmSTRIPAK can also be located at the nuclear envelope (PRO11, SCI1, SmMOB3 and PRO45). Transport along microtubules between the Golgi and ER as well as possible involvement of actin in short distance transport is suggested but not experimentally proven in *S. macrospora*.

### 3.10 The STRIPAK complex in *S. macrospora* is dynamic

Deletion of STRIPAK complex genes in *S. macrospora* results in strains with similar phenotypes suggesting that the SmSTRIPAK complex signaling requires all known SmSTRIPAK complex components for proper function (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015). In *N. crassa ham-2* (STRIP1/2), *ham-3* (striatin) and *ppg-1* (PP2Ac) deletion but not  $\Delta ham-4$  (SLMAP) or  $\Delta mob-3$  (MOB3) strains were highly reduced in protoperithecia formation and in hyphal growth (Dettmann *et al.*, 2013, Simonin *et al.*, 2010). It was suggested that HAM-2, HAM-3 and PPG-1 are most important for fruiting-body development and HAM-4 and MOB-3 fulfill accessory tasks (Dettmann *et al.*, 2013).

## Discussion

In *S. macrospora*, SCI1, PRO11, PRO22, SmPP2Ac1 and PRO45 seem to function in earlier developmental stages than SmMOB3 (Beier *et al.*, 2016, Bernhards & Pöggeler, 2011, Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015, Pöggeler & Kück, 2004). Analysis of the *sci1* deletion mutant showed that the phenotype of  $\Delta sci1$  is more similar to the  $\Delta pro11$  deletion strain phenotype compared to the other SmSTRIPAK complex deletion mutants (Figure 14).

The  $\Delta Smmob3$  strain but not the  $\Delta pro45$  still forms pigmented protoperithecia suggests a slightly different function or more important function in later developmental processes as described in *N. crassa* (Bernhards & Pöggeler, 2011, Nordzieke *et al.*, 2015).

STRIPAK complex components were located to many cell sites. In mammals, SLMAP localizes to the NE and centrosomes (Frost *et al.*, 2012), in *S. pombe* SIP components localize to spindle-pole bodies and Csc2 and Csc3 localize to the NE (Singh *et al.*, 2011). In *S. cerevisiae*, the Far complex proteins associate with the ER and the Golgi (Lisa-Santamaría *et al.*, 2012, Pracheil & Liu, 2013) and in *D. melanogaster* Cka translocates to the nucleus and transports autophagosomes (Chen *et al.*, 2002, Neisch *et al.*, 2017). STRIPAK complex orthologs HAM-2, HAM-3, HAM-4, MOB-3 but not PPG-1 in *N. crassa* were localized to the NE and punctate endomembrane system (Dettmann *et al.*, 2013). In *A. nidulans* and *F. verticillioides* the striatin orthologs StrA and Fsr1 respectively, localize to the NE and the ER (Wang *et al.*, 2010, Zhang *et al.*, 2017).

In *S. macrospora*, STRIPAK complex components SmMOB3, PRO45, SCI1 and PRO11 localize to the NE whereas PRO22 was localized to tubular vacuoles (Bloemendal *et al.*, 2012, Bloemendal *et al.*, 2010, Nordzieke *et al.*, 2015) (Figure 20, Figure S 12, Figure S 17 B and C). However, tubular structures were also identified with HA and eGFP tagged PRO11, DsRED tagged SCI1 and DsRED tagged SmMOB3 (Figure S 17 B and C). Additionally, vacuolar transport in the *sci1* deletion background seems to be disturbed but not completely abolished (Figure 22, Video 9).

Loss of *pro22* causes accumulation of loosely aggregated hyphae (Bloemendal *et al.*, 2010) instead of a densely packed peridium, which is a thick layer that encloses the developing asci (Lord & Read, 2011). Hyphal fusion occurs in the hyphae and also in the developing fruiting bodies. Cells in protoperithecia fuse and incorporate melanin when the peridium is formed (Lord & Read, 2011). In PRO11, SmMOB3 and SCI1 pull-downs coupled to LC/MS identified proteins of the vesicular transport machinery (Figure 8, Figure 18, Table S 1, Table S 2, Table S 3, Table S 4).

In *N. crassa*, hyphal fusion requires endo- and exocytosis as well as short distance transport of vesicles along actin (Berepiki *et al.*, 2010). Therefore, SCI1 might connect the SmSTRIPAK complex

## Discussion

to long and short distance transport required for hyphal fusion or stabilizes protein interactions in the SmSTRIPAK complex to ensure transport of yet unidentified cargoes.

The STRIPAK complex is a phosphatase and kinase complex, which suggests that the STRIPAK complex is regulated by phosphorylation events or regulates signaling pathways via phosphorylation or dephosphorylation of specific targets (Goudreault *et al.*, 2009). Deletion of the FHA domain of PRO45 renders *S. macrospora* sterile and hyphal-fusion defective whereas deletion of the TM domain, which is required for NE localization does not (Nordzieke *et al.*, 2015). In general, the FHA domain recognizes phosphothreonine epitopes on proteins and regulates protein interactions in a phosphorylation-dependent manner (Durocher & Jackson, 2002). Thus, the SLMAP ortholog PRO45 might be connected to phosphorylation (Nordzieke *et al.*, 2015). PRO45 interacts with PRO11, SmMOB3 and with SCI1 but not with PRO22 and SmPP2Ac1 (Nordzieke *et al.*, 2015). Up to now, PRO45 is the only SmSTRIPAK complex component in *S. macrospora*, which localizes to SPBs in the  $\Delta$ pro11 background indicating a unique function in targeting of SmSTRIPAK complex components to the SPBs, maybe for inheritance of the Golgi. In mammals, SG2NA, STRIP1 and MOB3 localize to the Golgi and depletion of MOB3 results in spindle failure (Baillat *et al.*, 2001, Frost *et al.*, 2012, Moreno *et al.*, 2001). Therefore, in *S. macrospora* Golgi derived vesicles, decorated with SmSTRIPAK complex components might be targeted by PRO45 to SPBs or to the ER (Figure 30).

Phosphatase activity of SmPP2Ac1 was shown to be required for fruiting-body formation (Beier *et al.*, 2016). The wild type *Smpp2ac1* under its endogenous promoter complemented the sterile  $\Delta$ Smpp2ac1 phenotype, hyphal fusion and fruiting bodies were detected again. Astonishingly, overexpression of a *tap-Smpp2ac1* construct partially complemented the sterile phenotype of Smpp2ac1 but no hyphal fusion was detected. It was concluded that hyphal fusion and fruiting-body development are not necessarily linked (Beier *et al.*, 2016). However, the phosphorylation status of distinct STRIPAK complex components might regulate the activity or localization of the whole complex.

Transition from protoperithecia to perithecia requires intensive cell wall remodeling, cell differentiation and growth (Lord & Read, 2011, Teichert *et al.*, 2014). The STRIP1/2 ortholog PRO22 in *S. macrospora* was located to vacuolar tubules and to ascogonia and might be required for long distance transport between protoperithecia and hyphae (Bloemendal *et al.*, 2010). PRO22, PP2AA

## Discussion

and SmPP2Ac1 interact and might target the SmSTRIPAK complex by dephosphorylation to developing protoperithecia (Figure 30).

**Figure 30: Hypothetical model of a dynamic STRIPAK complex in *S. macrospora***

The STRIPAK complex might be involved in transport processes in *S. macrospora*. PRO11, SmMOB3 and SCI1 pull-downs coupled to LC/MS and analysis of endosomal transport with fluorescence microscopy in *S. macrospora* suggest a direct interaction of the SmSTRIPAK with the transport machinery (short and long distance transport along actin or microtubule, respectively). Phosphatase and kinase activity might regulate SmSTRIPAK complex localization or transport of vesicles targeted by the SmSTRIPAK complex.

Kinases might counteract this mechanism and favor forward transport to vegetative hyphal compartments (Figure 30). Indeed, the STRIPAK complex has a role in vesicular transport in animals. Mammalian MOB3 (phocein) was shown to function in vesicular trafficking and membrane budding (Baillat *et al.*, 2002, Baillat *et al.*, 2001, Haeberlé *et al.*, 2006) and mammalian striatin was connected to dynein (Goudreault *et al.*, 2009). The kinase activator in *D. melanogaster* Mob4

## Discussion

regulates synapse formation, axonal transport and microtubule organization (Schulte *et al.*, 2010). Also, in *S. macrospora* *in silico* analysis of the kinase activator SmMOB3 suggests a role in vesicular transport (Bernhards & Pöggeler, 2011).

This thesis and previous studies show that the SmSTRIPAK complex of *S. macrospora* might be directly involved in short and long distance transport of vesicles/vacuoles required for hyphal fusion and fruiting-body development maybe including autophagy processes. Although, mutually exclusively interacting STRIPAK complexes were described in mammals (Goudreault *et al.*, 2009) protein interaction studies, localization of STRIPAK components in *S. macrospora*, phenotypes of SmSTRIPAK complex deletion mutants and protein pull-down experiments coupled to LC/MS argue for a dynamic SmSTRIPAK complex shuttling through the hyphae to mediate hyphal fusion and sexual development in filamentous fungi.

## 5. Supplement

**Figure S 1: LC/MS results of HAPRO11eGFP, FLAGSmMOB3 and SmMOB3eGFP pull-downs represented as heat maps and scatter plots**

Each pull-down and LC/MS **A/B**: HAPRO11eGFP, **C/D**: FLAGSmMOB3 and **E/F**: SmMOB3eGFP was performed in three biological replicates. For simplicity, the bait proteins and following 20 proteins identified are presented. The intensity scale between 16 and 28 is presented. The scatter plots show proteins calculated to be significant using the t-test (t-test difference  $< -3$  and  $p$ -value  $< 0.1$ ). Significant proteins are labeled in red and the locus tag is given.

Supplement

**Figure S 2: Heat maps of all proteins identified in LC/MS in 4 different pull-downs**

Each pull-down and LC/MS **A**: HAPRO11, **B**: HAPRO11eGFP, **C**: FLAGSmMOB3 and **D**: SmMOB3eGFP was performed in three biological replicates and the complete heat maps are given. Bait proteins are indicated with an arrow and the intensity scale between 16 and 28 is presented.

**Figure S 3: Alignment of small coiled-coil orthologs associated with the STRIPAK found in animals, fungi and yeasts**

Orthologs were identified with BLASTP search using amino acid sequences of human SIKE and FGFR1OP2 and *S. macrospora* SCI1. The multiple sequence alignment was performed with MAFFT version 7.182 (Katoh & Standley, 2013) using the amino-acid sequences: Sm SCI1, *S. macrospora* (XP\_003349276.1); Nc SCI, *N. crassa* (XP\_960970.1); Ct SCI, *Chaetomium thermophilum* (XP\_006696634.1); Vd SCI, *Verticillium dahliae* (EGY17808.1); Pa SCI, *Podospora anserina* (XP\_001912083.1); Mo SCI, *Magnaporthe oryzae* (XP\_003715088.1); Af SCI, *Aspergillus fumigatus* (XP\_752657.2); An SCI, *A. nidulans* (XP\_658614.1); Sc, *S. cerevisiae* Far3 (AAB39035) and Far7 (P43592); Sc Csc4, *S. pombe* Csc4 (O14043); Dm FGOP2, *D. melanogaster* FGOP2 (NP\_609084); Hs SIKE, *H. sapiens* SIKE (NP\_079349.2); Mm SIKE, *M. musculus* SIKE (NP\_079955.1); Gg SIKE, *Gallus gallus domesticus* SIKE (NP\_001006324.2); XI SIKE, *Xenopus laevis* SIKE (NP\_001085744.1); Dr SIKE, *Danio rerio* SIKE (XP\_696578.2); Hs 1FGFR1OP2, *H. sapiens* isoform 1 FGFR1OP2 (NP\_056448.1); Hs 2FGFR1OP2, *H. sapiens* isoform 2 FGFR1OP2 (NP\_001165358.1); Mm 1FGFR1OP2, *M. musculus* isoform 1 FGFR1OP2 (NP\_080494.1); Mm 2FGFR1OP2, *M. musculus* isoform 2 FGFR1OP2 (XP\_006536173.1); Gg FGFR1OP2, *G. domesticus* FGFR1OP2 (NP\_001007856.1); XI FGFR1OP2, *X. laevis* FGFR1OP2 (NP\_001079401.1); Dr FGFR1OP2, *D. rerio* FGFR1OP2 (NP\_956249.1).

The alignment is represented with GeneDoc (Nicholas & Nicholas, 1997). The overall protein lengths in amino acids are presented in brackets. The amino-acid regions used for the alignment are indicated at the right hand side at the end of the alignment. Amino acids conserved in all sequences are shaded in black, amino acids conserved in 19-23 of 24 sequences are shaded in dark gray and amino acids conserved in 10-18 of 24 sequences are shaded in light gray.

Supplement

**Figure S 4: Neighbor-joining tree and pair-wise comparison of SCI1 amino-acid sequences in filamentous ascomycetes**

Neighbor-joining tree **A** and pair wise comparison **B** of amino-acid sequences of Sm, *S. macrospora* (XP\_003349276.1); Nc, *N. crassa* (XP\_960970.1); Ct, *C. thermophilum* (XP\_006696634.1); Vd, *V. dahliae* (EGY17808.1); Pa, *P. anserina* (XP\_001912083.1); Mo, *M. oryzae* (XP\_003715088.1); Af, *A. fumigatus* (XP\_752657.2); An, *A. nidulans* (XP\_658614.1) aligned with MAFFT (Katoh & Standley, 2013). SCI1 orthologs of Sordariomycetes or Eurotiomycetes cluster together and the sequence identity is highest within a class.

**Figure S 5: Genome sequence of *sci1* and translated protein sequence**

The genome sequence of *sci1* with the corresponding translated protein sequence is presented. The intron at position 242-320 is shown in gray.

**Figure S 6: *sci1* fragment after quantitative reverse-transcription PCR**

The products of the quantitative reverse-transcription PCR using the primer pair RTsci1f/RTsci1r were resolved on a 2% agarose gel. The *sci1* fragment amplified from sexually and vegetatively grown *S. macrospora* wt had a size of 236 bp. The negative control supplemented with water is also presented. Marker: GeneRuler™ DNA Ladder Mix (Thermo Scientific).

## Supplement

**Figure S 7: Verification of the  $\Delta sci1_{hyg}\Delta pro11$  strain by PCR**

**A:** Schematic representation of the *sci1* ORF and **B:** the *pro11* ORF. Introns (green box), 5' flanking regions (blue) and 3' flanking regions (purple) are indicated. After homologous recombination the *hph* cassette replaced the whole *sci1* or the whole *pro11* ORF. Primer combinations and the corresponding fragment sizes are indicated. **C:** Verification of the *hph* cassette in the *sci1* and the *pro11* locus using PCR. Genomic DNA was isolated from wt and  $\Delta sci1_{hyg}\Delta pro11$  and tested with indicated primer (black arrows) combinations. The marker GeneRuler™ 1 kb DNA Ladder (Fisher Scientific) was used for gel-electrophoresis.

**Figure S 8: Growth of wt, pro11,  $\Delta$ pro11,  $\Delta$ sci1<sub>hyg</sub> and  $\Delta$ sci1<sub>hyg</sub>::5'sci1egfp under stress conditions**

Growth of strains wt, pro11,  $\Delta$ pro11,  $\Delta$ sci1<sub>hyg</sub>, and  $\Delta$ sci1<sub>hyg</sub>::5'sci1egfp on the indicated stress media for 7 days on petri dishes is presented. SWG was supplemented with H<sub>2</sub>O<sub>2</sub> (oxidative stress), NaCl, CaCl<sub>2</sub> sorbitol and glucose (osmotic stress), SDS (cell wall stress), calcofluor white (CFW) (cell wall stress/cell wall integrity pathway) or prepared without KNO<sub>3</sub> (nitrogen starvation) as indicated.

## Supplement

**Figure S 9: Y2H growth control of full length and fragments of PRO11, SCI1 and full length Far3, Far7 and Far8**

Indicated constructs fused to the Gal4-activating domain or binding-domain sequence were cotransformed into PJ69-4A and 20  $\mu$ L of each strain with an OD<sub>600</sub> 0.1 was dropped onto selective medium. The growth control show the respective combinations on synthetic defined medium without leucine and tryptophan (SD-LT). **A:** growth controls for interaction studies of SCI1, PRO11 and PRO45 including fragments of SCI1, PRO11 and PRO45. **B:** growth control for interaction studies of Far3, Far7 and Far8 with SCI1 and SCI1 fragments.

## Supplement

**Figure S 10: Heat maps of all proteins identified in LC/MS in three SCI1eGFP pull-downs**

SCI1eGFP pull-downs were performed in three biological replicates and the complete heat map is given. The bait protein SCI1eGFP is indicated with an arrow and the intensity scale between 16 and 28 is presented.

## Supplement

**Figure S 11: Western blot using anti-GFP and anti-DsRED for detection of fusion proteins expressed in *S. macrospora***

Synthesis of **A:** SCI1eGFP, **B:** SCI1DsRED, **C:** HAPRO11eGFP, **D:** SCI1DsRED and HAPRO11eGFP and **E:** SmpPOM152eGFP fusion proteins (black arrow) in the respective strains was successfully shown by Western blot experiments. The *sci1* gene fused to a *egfp* or *Dsred* was either under the control of the endogenous *sci1* promoter (5'*sci1egfp*) or under the control of the promoter of the *clock controlled gene 1* of *N. crassa* (*sci1egfp*). Also the *hapro11egfp* fusion gene was under the control of the promoter of the *clock controlled gene 1* of *N. crassa*. Proteins isolated from indicated strains were detected with anti-GFP or anti-DsRED. The wt::egfp and wt::Dsred strains served as controls. The apparent molecular weight of the fusion proteins, eGFP and DsRED is indicated in kDa.

Supplement

**Figure S 12: Colocalization of SCI1DsRED and HAPRO11eGFP and visualization of nuclei**  
 SCI1DsRED and HAPRO11eGFP colocalized in roundish structures around nuclei stained with DAPI. Both fusion proteins also localized to thread like structures and punctiform structures in the cytoplasm. Scale bar: 20 $\mu$ m.

**Figure S 13: Nuclei, mitochondria and the ER in wt and  $\Delta sci1$**   
**A:** Nuclei, **B:** Mitochondria, and **C:** Endoplasmic reticulum (ER) were visualized in vegetative hyphae of *S. macrospora* using indicated marker proteins tagged with red fluorescent protein DsRED or TdTomato. Scale bar size: 20  $\mu$ m

Supplement

**A**

**B**

**Figure S 14: PCR and Southern blot analysis of wt,  $\Delta sci1_{hyg}$  and,  $\Delta sci1_{nat}$**

**A:** Schematic representation of the *sci1* ORF with one intron (green box), 5' flanking region (blue) and 3' flanking region (purple). After homologous recombination the resistance cassettes (either *nat* or *hph*) replaced the whole *sci1* ORF. Primer combinations and the corresponding fragment sizes are indicated. The probe size and hybridization region is also indicated. **B:** Verification of homologous integration of the *hph* or the *nat* cassette into the *sci1* locus using PCR. Genomic DNA was isolated from wt,  $\Delta sci1_{hyg}$  and  $\Delta sci1_{nat}$  strains and tested with indicated primer combinations. The marker, GeneRuler™ 1 kb DNA Ladder (Fisher Scientific) was used for both gel-electrophoresis and Southern blot. The fragments are given in bp for identification of the amplicons or in kb for the Southern blot. **C:** Confirmation of the  $\Delta sci1_{hyg}$  and  $\Delta sci1_{nat}$  strain was done by Southern blot. The isolated gDNA was hydrolyzed with *NcoI*. The probe and the marker were labeled with alkaline phosphatase and signals were detected on X-ray films. Signals detected correspond to a fragment size of 2.0 kb for wt, 2.6 kb for  $\Delta sci1_{hyg}$  and 4.8 kb for  $\Delta sci1_{nat}$ .

## Supplement

**Figure S 15: Fluorescence microscopy of the wt::egfp control strain and strains stained with FM4-64**  
**A:** Signal of free eGFP in hyphae of the control strain wt::egfp. **B:** The indicated strains were stained with the red fluorescence dye FM4-64. FM4-64 entered through the hyphal tip and was localized to membrane-containing structures in old hyphae. Scale bar: 20  $\mu$ m

**Figure S 16: Detection of eGFPZtRab5 and eGFPZtRab7 using anti-GFP in Western blot analysis**  
 Proteins from wt::egfpZtRab5,  $\Delta sci1_{nat}::egfpZtRab5$ , wt::egfpZtRab7 and  $\Delta sci1_{nat}::egfpZtRab7$  were isolated and Western blot was performed. Fusion proteins eGFPZtRab5 and eGFPZtRab7 were detected with anti-GFP. The wt::egfp strain served as control. The apparent molecular weight of the presented fusion proteins is indicated in kDa.

**Figure S 17: Localization of the endosomal reporter eGFPZtRab7 and of SmMOB3DsRED, SCI1DsRED and HAPRO11eGFP fusion proteins in vegetative hyphae of *S. macrospora***

**A:** eGFPZtRab7 was observed in old hyphae of the  $\Delta sci1_{nat}$  and wt background. Hyphae of wt::egfpZtrab7 and  $\Delta sci1::egfpZtrab7$  were stained with CMAC to visualize vacuoles in middle old to old hyphae. **B:** Representation of structures visualized by SmMOB3DsRED, SCI1DsRED and HAPRO11eGFP fusion proteins in the indicated strains. **C:** In each picture, from left to right, the apex, the subapical region and the postapical region are shown. Fluorescent signals in  $\Delta Smmob3\_gpd$ -MOB3:Dsred,  $\Delta sci1_{hyg}::sci1Dsred$  and  $\Delta pro11::hapro11egfp$  hyphae stained the nuclear envelope (white arrow), small or big punctiform structures and tubular structures. Scale bars: 20  $\mu m$ .

**Table S 1: Proteins enriched with HAPRO11 and with HAPRO11eGFP in pull-down experiments coupled to LC/MS**

Locus tag	Description	LC/MS1	LC/MS2	LC/MS3
SMAC_00646	hypothetical protein	10	4	39
SMAC_00877	SmMOB3	3	45	30
SMAC_01171	hypothetical protein	7	2	10

SMAC_08842	glycyl-tRNA synthetase	10	9	31

Pull-downs and LC/MS were performed in three biological replicates (MS1-3). LC/MS data from HAPRO11 and HAPRO11eGFP pull-downs were combined for analysis with the Proteome Discoverer™. Criteria: at least two peptides per protein, peptide mass confidence high, not enriched in the negative controls and sum of spectral counts at least 7 in two of three LC/MS experiments. PRO11 indicated in bold was highly enriched in all replicates. The sum of spectral counts in LC/MS1-3 are given in numbers. The locus tag and corresponding description of protein (determined by the best BLASTP value) are given.

## Supplement

**Table S 2: Proteins enriched with FLAGSmMOB3 and with SmMOB3eGFP in pull-down experiments coupled to LC/MS**

Locus tag	Description	LC/MS1	LC/MS2	LC/MS3
<b>SMAC_00877</b>	<b>SmMOB3</b>	<b>80</b>	<b>66</b>	<b>122</b>
SMAC_02409	putative nucleoporin protein/NIC 96	12	6	8
SMAC_04517	hypothetical protein	9	6	11
SMAC_05008	putative myosin-5 protein	11	6	9
SMAC_08794	PRO11	80	88	124
SMAC_09495	AP-2 complex subunit alpha	9	6	11

Pull-downs and LC/MS were performed in three biological replicates (MS1-3). LC/MS data from FLAGSmMOB3 and SmMOB3eGFP pull-downs were combined for analysis with the Proteome Discoverer™. Criteria: at least two peptides per protein, peptide mass confidence high, not enriched in the negative controls and sum of spectral counts at least 7 in two of three LC/MS experiments. SmMOB3 indicated in bold was highly enriched in all replicates. The sum of spectral counts in LC/MS1-3 are given in numbers. The locus tag and corresponding description of protein (determined by the best BLASTP value) are given.

**Table S 3: Proteins enriched with HAPRO11/HAPRO11eGFP and FLAGSmMOB3/SmMOB3eGFP in pull-down experiments coupled to LC/MS**

Locus tag	Description	HAPRO11/ HAPRO11GFP			FLAGSmMOB3/ SmMOB3eGFP		
		LC/MS 1	LC/MS 2	LC/MS 3	LC/MS 1	LC/MS 2	LC/MS 3

SMAC_06043	glycosyltransferase family 20 protein	8	5	10
SMAC_06237	Iki3 family protein	8	13	9

## Supplement

SMAC_06397	putative RasGAP	14	8	2
<b>SMAC_07234</b>	<b>aminotransferase</b>	<b>15</b>	<b>16</b>	<b>4</b>
SMAC_08299	ARM repeat-containing protein, Vac14,	16	31	2
SMAC_08770	non-anchored cell wall protein 1	15	16	6
SMAC_08794	PRO11	73	81	110

Pull-downs and LC/MSs were performed in three biological replicates (MS1-3). LC/MS data from SCI1eGFP pull-downs were combined for analysis with the Proteome Discoverer™. Criteria: at least two peptides per protein, peptide mass confidence high, not enriched in the negative controls and sum of spectral counts at least 7 in two of three LC/MS experiments. SCI1eGFP indicated in bold was highly enriched in all replicates. The sum of spectral counts in LC/MS1-3 are given in numbers. The locus tag and corresponding description of protein (determined by the best BLASTP value) are given. Proteins identified and defined as significant with MaxQuant/Perseus are marked in orange.

### **Video 1: Nuclei in young hyphae of wt::h2btdTomato**

Nuclei were visualized by histone 2 B fused to TdTomato and move freely within the hyphae of wt::h2btdTomato. Recording: 46 stacks, exposure time: 100 ms/2 sec for 1.5 min, video length: 1.077 min, **DICV1:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20µm

### **Video 2: Nuclei in young hyphae of Δsci1<sub>hyg</sub>::h2btdTomato**

Nuclei were visualized by histone 2 B fused to TdTomato and move freely within the hyphae of Δsci1<sub>hyg</sub>::h2btdTomato. Recording: 61 stacks, exposure time: 500 ms/1 sec for 1 min, video length: 1.508 min, **DICV2:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20µm

### **Video 3: Mitochondria in young hyphae of wt::mitoDsred**

The reporter protein CAS2(AA1-60) fused to DsRED visualized mitochondria in hyphae of wt::mitoDsred strain. **DICV3:** Hyphae in visualized by differential interference contrast (DIC). Recording: 31 stacks, exposure time: 500 ms/2 sec for 1 min, video length: 1.258 min, Scale bar: 20µm

### **Video 4: Mitochondria in hyphae of Δsci1<sub>hyg</sub>:: mitoDsred**

The reporter protein CAS2(AA1-60) fused to DsRED visualized mitochondria in hyphae of Δsci1<sub>hyg</sub>::mitoDsred. Recording: 91 stacks, exposure time: 100 ms/2 sec for 3 min, video length: 3.152 min, **DICV4:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20µm

### **Video 5: Actin polymerization in young hyphae of wt::lifeact-tagrfp**

The wt strain was transformed with the plasmid pAL-4Lifeact and actin polymerization in young hyphae was visualized. Lifeact-TagRFP visualized actin, distributed in a defined region along the cell wall. Then, actin polymerizes in a hill like structure, which most likely represents the contraction of the actin ring preceding septum formation. Recording: 25 stacks, exposure time: 500 ms/1 sec for 0.8 min, video length: 1.008 min, **DICV5:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20µm

### **Video 6: Actin polymerization in hyphae of $\Delta$ sci1<sub>hyg</sub>::lifeact-tagrfp**

The  $\Delta$ sci1 strain was transformed with the plasmid pAL-4Lifeact to visualize actin polymerization in young hyphae. Although, the Lifeact-TagRFP signal was very weak in  $\Delta$ sci1::lifeact-tagrfp compared to the wt::lifeact-tagrfp actin polymerization was visualized. Actin was distributed in a defined region along the cell wall, then, formed a hill like structure, which most likely represents the contraction of the actin ring preceding septum formation. **DICV6:** Hyphae in visualized by differential interference contrast (DIC). Recording: 31 stacks, exposure time: 500 ms/1 sec for 1 min, video length: 1.258 min, Scale bar: 20 $\mu$ m

### **Video 7: Structures visualized by early endosome marker eGFPZtRab5 in young hyphae of wt::egfpZtrab5**

The plasmid pHEGFPRAB5 was transformed into the wt strain. The EE marker eGFPZtRab5 visualized EE, continuously changing punctiform structures and tubular/vacuolar structures in young hyphae. Recording: 121 stacks, exposure time: 100 ms/1 sec for 2 min, video length: 2.202 min, **DICV7:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20 $\mu$ m

### **Video 8: Structures visualized by EE marker eGFPZtRab5 in young hyphae of $\Delta$ sci1<sub>nat</sub>::egfpZtrab5**

The plasmid pHEGFPRAB5 was transformed into the  $\Delta$ sci1 strain. The EE marker eGFPZtRab5 visualized EE, big punctiform structures incorporating vesicles. Recording: 121 stacks, exposure time: 200 ms/1 sec for 2 min, video length: 2.403 min, **DICV8:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20 $\mu$ m

### **Video 9: The EE marker eGFPZtRab5 in young hyphae of $\Delta$ sci1<sub>nat</sub>::egfpZtrab5 visualized “cloudy” structures**

In the post-apical region of young hyphae of  $\Delta$ sci1::egfpZtrab5 sometimes, big punctiform structures dissolved into “clouds” around dark regions most likely representing nuclei and reformed again. Recording: 121 stacks, exposure time: 100 ms/1 sec for 2 min, video length: 2.202 min, **DICV9:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20 $\mu$ m

### **Video 10: Structures visualized by late endosome marker eGFPZtRab7 in young hyphae of wt::egfpZtrab7**

The plasmid pHEGFPRAB7 was transformed into the wt strain. The LE marker eGFPZtRab7 visualized LEs fusing and splitting again to and from tubular structures in young hyphae. **DICV10:** Hyphae in visualized by differential interference contrast (DIC). Recording: 121 stacks, exposure time: 300 ms/1 sec for 2 min, video length: 2.605 min, Scale bar: 20 $\mu$ m

### **Video 11: Structures visualized by the LE marker eGFPZtRab7 in young hyphae of $\Delta$ sci1<sub>nat</sub>::egfpZtrab7**

The plasmid pHEGFPRAB7 was transformed into the  $\Delta$ sci1 strain. The LE marker eGFPZtRab7 visualized vesicles and vacuolar structures in young hyphae of  $\Delta$ sci1::egfpZtrab7, which were scattered compared to the wt and did not form a long tubular network. Recording: 121 stacks, exposure time: 300 ms/1 sec for 2 min, video length: 2.605 min, **DICV11:** Hyphae in visualized by differential interference contrast (DIC). Scale bar: 20 $\mu$ m

## 6. Danksagung

An erster Stelle möchte ich mich herzlich bei meiner Doktormutter, Prof. Dr. Stefanie Pöggeler, für die Möglichkeit in ihrer Arbeitsgruppe zu promovieren, bedanken. Ich danke ihr insbesondere für ihr fortwährendes Interesse an dieser Forschungsarbeit, die hilfreichen Anregungen, die wissenschaftlichen und persönlichen Diskussionen, sowie das mir entgegengebrachte Vertrauen.

Außerdem bedanke ich mich bei den Mitgliedern meines „Thesis Committees“, Prof. Dr. Gerhard Braus und Prof. Dr. Henning Urlaub für die wertvollen Hinweise und Anmerkungen, die maßgeblich in diese Arbeit miteingeflossen sind.

Im Zuge dessen möchte ich mich auch bei Dr. Oliver Valerius für die Zusammenarbeit bedanken, die dazu beigetragen hat, den Fortgang dieses Projekt zu ermöglichen.

Ich möchte mich auch bei Dr. Britta Herzog und Dr. Steffen Nordzieke für die Durchsicht dieser Dissertationsarbeit, sowie Dr. Steffen Nordzieke für die ein oder anderen humorvollen Bemerkungen und für die „Last-Minute-Bilder“ bedanken. Des Weiteren gilt mein Dank auch Dr. Antonia Werner und Dr. Daniela Nordzieke für die kollegiale Zusammenarbeit, Unterstützung und den Austausch über wissenschaftliche sowie private Themen.

Gertrud Stahlhut danke ich für ihre Mithilfe an den Experimenten die sich in dieser Arbeit wiederfinden und vor allem für ihre immer ehrliche, offene und hilfsbereite Art. Mein Dank gilt ebenso Silvia Carrillo-Castellón, die sich um die Versorgung mit Arbeitsmaterialien kümmert. Auch danke ich Fereshteh Sadeqi, die während ihrer Bachelor Arbeit an diesem Projekt mitgearbeitet hat und Dr. Blaga Popova für die Hilfe in „Hefe-Fragen“.

Meinen Eltern und meiner Schwester danke ich besonders für die Motivation und die Unterstützung in allen Lebenslagen. Daneben gilt mein Dank meinen Schwiegereltern und meinem Schwager für den Rückhalt. Zwei besonderen Menschen möchte ich noch danken, meinem Ehemann für seine grenzenlose Geduld und Unterstützung sowie meinem Sohn. Ihr erfüllt mein Leben jeden Tag mit Sinn und Freude.

## 7. Curriculum vitae

Eva Johanna Reschka  
Georg-August University Göttingen  
Institute of Microbiology and Genetics  
Department of Genetics of Eukaryotic Microorganisms  
Grisebachstraße 8  
Göttingen, Germany  
E-mail: ereschk@gwdg.de

Date of birth: July 17<sup>th</sup> 1984  
Place of birth: Tarnowitz (Poland)  
Nationality: German

### Academic Education:

- Since 03/ 2013      PhD student in the GGNB program “Microbiology and Biochemistry”,  
Department of Genetics of Eukaryotic Microorganisms, Georg-August  
University Göttingen, Germany  
Title of the Thesis: Functional analysis of STRIPAK complex components in  
the filamentous ascomycete *Sordaria macrospora*  
Thesis Committee: Prof. Dr. Stefanie Pöggeler, Prof. Dr. Gerhard Braus, Prof.  
Dr. Henning Urlaub
- 12/ 2012- 02/2013      Research assistant, Department of Genetics of Eukaryotic Microorganisms,  
Georg-August University Göttingen, Germany
- 10/ 2010 – 09/ 2012      Master of Science, M.Sc Microbiology and Biochemistry  
Department of Genetics of Eukaryotic Microorganisms, Georg-August  
University Göttingen, Germany  
Title of the Master thesis: Co-IP of STRIPAK complex proteins in *Sordaria  
macrospora* and identification of new SmPP2AA and PRO11 interaction  
partners
- 09/ 2007 – 07/ 2010      Bachelor of Science, B.Sc Applied Biology, Hochschule Bonn-Rhein-Sieg  
University of Applied Sciences, Germany  
„Double Degree” Bioscience with Biomedical Science, Robert Gordon  
University Aberdeen, UK  
Title of the Bachelor thesis: Sex identification of mammals by PCR  
amplification of Zfx/Zfy intronic regions

### School Education:

- 09/ 2001 – 06/ 2004      Konrad-Adenauer-Gymnasium, Bad Godesberg (Abitur)

## Curriculum vitae

### Talks:

- 10/2015 Minisymposium, Department for General and Molecular Botany,  
Prof. Dr. Ulrich Kück, Ruhr-University Bochum, Germany  
“SCI1, a new STRIPAK interaction partner in *Sordaria macrospora*”
- 10/2015 Summerschool 2015, Proteomics and Mass Spectrometry, Department of  
Genetics of Eukaryotic Microorganisms, Georg-August University Göttingen,  
Germany  
“Analysis of LC/MS data identified several STRIPAK complex components in  
*Sordaria macrospora*”
- 10/2014 Retreat of the GGNB program “Microbiology and Biochemistry”  
“Identification and characterization of new STRIPAK complex components  
in *Sordaria macrospora*”

### Posters:

- 12/2016 4th GGNB Science Day at the Georg-August University Göttingen, Germany  
“A new STRIPAK interaction partner in *Sordaria macrospora*”
- 10/2015 VAAM 2014 Berlin, Germany “A new STRIPAK interaction partner in *Sordaria  
macrospora*”
- 03/2015 28th Fungal Genetics Conference in Asilomar, California, USA  
“Analysis of SCI1, a potential new interaction partner of the STRIPAK  
complex”
- 10/2014 VAAM 2014 Dresden, Germany “Analysis of SCI1, a potential interaction  
partner of the STRIPAK complex”

### Publications:
