# Intermetallic $\sigma$ and $\pi$ Communication in Heterodinuclear $\mu$-Cyclooctatetraene Complexes** 

Gerdjan Bögels, Hugo C. Brussaard, Ute Hagenau, Jürgen Heck,* Jürgen Kopf, Johannes G. M. van der Linden, and Annie Roelofsen<br>Dedicated to Professor Gottfried Huttner on the occasion of his 60th birthday

#### Abstract

The reaction of $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left(\eta^{6}-\right.\right.$ Cot)] ( $\mathrm{R}=\mathrm{H}, \mathrm{Me}$; Cot = cyclooctatetraene) with $\left[(\mathrm{CO})_{3} \mathrm{Fe}(\eta \text {-cis-cyclooctene })_{2}\right]$ affords the heterodinuclear complexes $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{3}\right]$ ( $\mathrm{R}=\mathrm{H}: 1, \mathrm{R}=\mathrm{Me}: 2$ ) in quite good yields. One of the CO ligands in $\mathbf{1}$ and 2 can be easily substituted by a phosphane ligand, $\mathrm{PR}_{3}^{\prime}\left(\mathrm{R}^{\prime}=\mathrm{Me}, \mathrm{Ph}, \mathrm{OEt}, \mathrm{F}\right)$ to obtain $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})\right.\right.$ - Cot$\} \mathrm{Fe}-$ $\left.(\mathrm{CO})_{2} \mathrm{PR}_{3}^{\prime}\right]\left(\mathrm{R}=\mathrm{H}, \mathrm{R}^{\prime}=\mathrm{Me}: \mathbf{3 a} ; \mathrm{R}=\right.$ $\mathrm{H}, \mathrm{R}^{\prime}=\mathrm{Ph}: \mathbf{3 b} ; \mathrm{R}=\mathrm{Me}, \mathrm{R}^{\prime}=\mathrm{Me}: \mathbf{4 a}$; $\mathrm{R}=\mathrm{Me}, \mathrm{R}^{\prime}=\mathrm{Ph}: 4 \mathrm{~b} ; \mathrm{R}=\mathrm{Me}, \mathrm{R}^{\prime}=$ OEt: $4 \mathbf{c} ; \mathrm{R}=\mathrm{Me}, \mathrm{R}^{\prime}=\mathrm{F}: 4 \mathrm{~d}$ ). The $\mathrm{X}-$ ray structure determinations of $2,3 \mathrm{a}$, and

4 c showed exclusively synfacial coordination of the two metal ligand moieties, despite the bulky $\mathrm{C}_{5} \mathrm{Me}_{5}\left(\mathrm{Cp}^{*}\right)$ ligand in 2 and 4 c . However, the steric demand of Cp* gives rise to structural distortions in 2 and 4 c , compared to the Cp -containing products 1 and $3 \mathbf{a}$, and an elongation of the $\mathrm{Cr}-\mathrm{Fe}$ distance from 293 pm to 303

and 304 pm , respectively. The heterodinuclear complexes were investigated by cyclic voltammetry and ESR spectroscopy in order to elucidate the role of the permethylation of the cyclopentadienyl ligand and the influence of phosphane ligands with different $\pi$-accepting abilities. The ESR spectroscopic results reveal surprisingly large ${ }^{31} \mathrm{P}$ hyperfine coupling constants (hfcc). These can be explained by a superposition of two different electron spin transfer mechanisms, which include a $\sigma$ - and a $\pi$-bonding mode between the Cr and Fe centers.

## Introduction

In order to obtain a deeper insight into intermetallic communications in heterodinuclear complexes, we have examined the mutual influence of the metal centers in heterodinuclear complexes with a bridging cyclooctatetraene (Cot) ${ }^{[1,2]}$ which do not obey the 34 valence electron (VE) rule for dinuclear cy-cloolefinic-bridged complexes. ${ }^{[3,4]}$ In complexes with 34 VE two stable stereoisomers have been obtained, which show a synfacial (A) and an antifacial (B) coordination mode. ${ }^{[4-6]}$

Interestingly, both the antifacial and the synfacial complexes are diamagnetic, although a direct metal-metal bond can be excluded in the former because of the long metal - metal distance

[^0]

A
synfacial

B
antifacial

( $>370 \mathrm{pm}$ ). The strong electron-electron coupling between the metal centers must therefore occur through the bridging organic $\pi$ ligand. Hence, it would be worthwhile to get more information about the interaction between both metal centers in antifacial $\mu$-Cot complexes in comparison to corresponding synfacial derivatives. When compounds are paramagnetic, as in 33 VE complexes, ESR spectroscopy has been shown to be a very powerful tool for this purpose. ${ }^{[1,2]}$ There have not yet been any reports published on the successful synthesis of an antifacial complex with 33 VE . Since steric effects of the permethylated cyclopentadienyl ligand $\mathrm{Cp}{ }^{*}$ can force the formation of an antifacial configuration in some cases, ${ }^{55]}$ we employed $\left[\mathrm{CpCr}\left(\eta^{6}-\right.\right.$ $\mathrm{Cot})]$ and $\left[\mathrm{Cp}{ }^{*} \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right]^{[7]}$ as the starting materials for synthesizing dinuclear paramagnetic 33 VE complexes of general

Complexes 1 and 2 reacted with phosphanes with substitution of one of the carbon monoxide ligands [Eq. (2), for substituents $R$ and $R^{\prime}$, see Table 1].

Table 1. Selected IR data for $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}(\mu-\mathrm{Cot}) \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{~L}\right]$,

|  | R | L | $\tilde{v}(\mathrm{CO})\left[\mathrm{cm}^{-1}\right]$ |
| :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | H | CO | 2003,1930 |
| $\mathbf{3 a}$ | H | $\mathrm{PMe}_{3}$ | 1932,1881 |
| $\mathbf{3 b}$ | H | $\mathrm{PPh}_{3}$ | 1936,1886 |
| $\mathbf{2}$ | Me | CO | 1996,1925 |
| $\mathbf{4 a}$ | Me | $\mathrm{PMe}_{3}$ | 1924,1872 |
| $\mathbf{4 b}$ | Me | $\mathrm{PPh}_{3}$ | 1924,1879 |
| $\mathbf{4 c}$ | Me | $\mathrm{POEt}_{3}$ | 1936,1885 |
| $\mathbf{4 d}$ | Me | $\mathrm{PF}_{3}$ | 1968,1924 |

The reaction was monitored by IR spectroscopy. The starting compounds 1 and 2 show strong $v(\mathrm{CO})$ absorption bands at 2003 and $1930 \mathrm{~cm}^{-1}$ and 1996 and $1925 \mathrm{~cm}^{-1}$, respectively, which are characteristic for a $\mathrm{M}(\mathrm{CO})_{3}$ unit with local $C_{3 v}$ symmetry. These bands disappear, and two new $v(\mathrm{CO})$ bands of almost equal intensities appear at lower wavenumbers (Table 1). The yields of the desired phosphane-containing products were between 10 and $76 \%$.

In the synthesis of $\mathbf{3 a}$, small amounts of volatile by-products were isolated in a cold-trap after the reaction mixture had been dried in vacuo. IR spectroscopic studies indicated the formation of $\left[\mathrm{Fe}(\mathrm{CO})_{5}\right]$ and its $\mathrm{PMe}_{3}$ derivatives $\left[\mathrm{Fe}(\mathrm{CO})_{5-x}\left(\mathrm{PMe}_{3}\right)_{x}\right]$ $(x=1,2,3) .{ }^{[9]}$

Structural Analyses: The X-ray structure analyses of 2, 3a, and 4 c (Figure 1, Table 2, and Table 7) revealed only synfacial configurations for the $\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}$ and $(\mathrm{CO})_{2} \mathrm{LFe}\left(\mathrm{L}=\mathrm{CO}, \mathrm{PR}_{3}^{\prime}\right)$ units regardless of the nature of $\mathrm{R}(\mathrm{R}=\mathrm{H}, \mathrm{Me})$. The phospho-rus-containing ligands in $\mathbf{3 a}$ and $\mathbf{4 c}$ are coordinated to the Fe center and are trans to the Cr atom. The Cot ligands are bound in an $\eta^{5}$ mode to the chromium center and $\eta^{3}$ to the iron center. This arrangement causes an interruption in the conjugation of the Cot carbon atoms, as shown by the distinct elongation of the $C(3)-C(4)$ and $C(6)-C(7)$ bond lengths (Table 2). The $\mathrm{Cr}-\mathrm{C}_{\mathrm{Cot}}$ bond lengths are similar to those observed for ( $\eta^{5}$-pentadienyl)chromium fragments, ${ }^{[10]}$ and the $\mathrm{Fe}-\mathrm{C}_{\mathrm{Cat}}$ distances show the same long-short-long alternation as that seen in $\left[\left\{\left(\eta^{3}\right.\right.\right.$ $\left.\left.\left.\mathrm{C}_{3} \mathrm{H}_{5}\right) \mathrm{Fe}(\mathrm{CO})_{3}\right\}_{2}\right]^{[11]}$ and other heterodinuclear Fe complexes that contain an $\eta^{3}(\mathrm{Fe})$-allylic bonding mode of the olefinic ligand. ${ }^{[12]}$ The $\mathrm{Cr}-\mathrm{Fe}$ distance is 292.83 (8) pm for the Cp derivative 3 a , which is almost identical to the $\mathrm{Cr}-\mathrm{Fe}$ distance in $\mathrm{I},{ }^{[2]}$ and about 10 pm longer for the Cp * compounds 2 and 4 c as a result of the steric demand of the $\mathrm{Cp} *$ ligand. These metalmetal distances represent a long $\mathrm{Cr}-\mathrm{Fe}$ single bond, when compared to those found in other $\mathrm{Cr} / \mathrm{Fe}$ species ${ }^{[13]}$ and to the hypothetical $\mathrm{Cr}-\mathrm{Fe}$ single-bond length of 320 pm , estimated from the metal-metal distances in $\left[\left\{\mathrm{CpCr}(\mathrm{CO})_{3}\right\}_{2}\right]^{[14]}$ and $\left[\left\{\left(\eta^{3}-\right.\right.\right.$ allyl) $\left.\left.\mathrm{Fe}(\mathrm{CO})_{3}\right\}_{2}\right] .{ }^{[11]}$

Figure 1. OR'TEP drawings of the molecular structure of $2,3 a$, and $4 c$ (the hydrozen atoms are omitted for clarity, ellipsoids at the $50 \%$ probability level).

The steric demand of the bulky Cp* ligand is also indicated by several other structural features:

1) The $\mathrm{Cr}-\mathrm{C}(10)$ bond in $\mathbf{2}$ and $\mathbf{4 c}$ is about $6-8 \mathrm{pm}$ longer than the shortest bond between the Cr center and the cyclopentadienyl ligand, while the corresponding difference in Cp derivatives such as $\mathbf{1}$ and $\mathbf{3 a}$ is about 3.5 pm .
2) The Me group $\mathrm{C}(101)$ is deflected by about $10^{\circ}$ from the cyclo- $\mathrm{C}_{5}$ plane of $\mathrm{Cp}^{*}$ (Figure 1).
3) The cyclopentadienyl plane and $\eta^{5}$-Cot plane show a larger deviation from parallelism in $\mathbf{2}$ and $\mathbf{4 c}$ than in 3a (Table 2).

The substitution of one CO by a phosphorus-containing ligand only influences the $\mathrm{Cr}-\mathrm{Fe}$ distance slightly, if at all (see complex 2 and 4 c ), and results in a small $\mathrm{Fe}-\mathrm{C}(14)$ and $\mathrm{Fe}-\mathrm{C}(15)$ bond shortening and a corresponding $\mathrm{C}(14)-\mathrm{O}(14)$ and $\mathrm{C}(15)-\mathrm{O}(15)$ bond elongation due to increased $\pi$ back donation from the Fe center to the remaining CO ligands. This is also confirmed by the low-energy shift of the CO stretching vibration in $\mathbf{3 a}, \mathbf{b}$ and $\mathbf{4 a}$-d relative to those of $\mathbf{1}$ and $\mathbf{2}$ (Table 1).

ESR Spectroscopy: All of the heterodinuclear compounds presented here show highly resolved solution ESR spectra with hyperfine structure (hfs) from ${ }^{1} \mathrm{H}$ and ${ }^{53} \mathrm{Cr}$ as well as hfs from ${ }^{31} \mathrm{P}$ in $3 \mathbf{a}, \mathrm{~b}$ and $4 \mathbf{a}-\mathbf{d}$ (Figure 2). The hf coupling constants (hfcc) (Table 3) were determined by calculations of the experimental spectra. The $g_{\text {iso }}$ values obtained in this way as well as ${ }^{1} \mathrm{H}$ and ${ }^{53} \mathrm{Cr}$ hfcc strongly resemble those of the mononuclear com-

$[\mathrm{a}] \pm<0.001$ for $1,3 \mathrm{a}: \pm<0.0005$ for $2,3 \mathrm{~b}, 4 \mathrm{a}-4 \mathrm{~d}$. [b] $\pm<0.002$. [c] $\ln$ Gauss, $\pm<0.5$. [d] $\ln$ Gauss, $\pm<0.1$ except for 1 . [e] In Gauss, $\pm<0.2 .[\mathrm{Cf}] a\left({ }^{19} \mathrm{~F}\right)=5.5(1) \mathrm{G}$.
plexes $\left[\mathrm{CpCr}\left(\eta^{6}-\mathrm{Cot}\right)\right]$ and $\left[\mathrm{Cp}{ }^{*} \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right] .{ }^{[7]}$ These results justify the assumption that the unpaired electron is predominantly localized in a $\mathrm{d}_{z^{2}}$-type orbital at the Cr center. When a direct spin delocalization from the semi-occupied $\mathrm{d}_{\mathrm{z}^{2}}$-type orbital of the Cr center into the $\mathrm{C}-\mathrm{H} \sigma$ bond is taken into account, ${ }^{[15 a]}$ the value of the ${ }^{1} \mathrm{H}$ hfcc is found to depend on the distance between the metal and the corresponding carbon atom. ${ }^{[156]}$ Therefore the assignments of the ${ }^{1} \mathrm{H}$ hfce in Table 3 are based on structural arguments. In comparison to the mononuclear complexes, the ${ }^{1} \mathrm{H}$ hfs of the dinuclear species is reduced by one ${ }^{1} \mathrm{H}$ hfec with $a\left(1^{1} \mathrm{H}\right)>3 \mathrm{G}$, which is in accordance with the change in the hapticity with which the Cot ligand coordinates to the Cr center on going from the mononuclear $\eta^{6}(\mathrm{Cr})$ to the dinuclear $\eta^{5}(\mathrm{Cr})$ bonding mode. The isotopic $g$ values of the dinuclear complexes show a slight increase for 14d compared to the mononuclear compounds $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left(\eta^{6}\right.\right.$ $\operatorname{Cot})](\mathrm{R}=\mathrm{H}, \mathrm{Me})$, indicating the subtle influence of the heavier atoms Fe and P .
The solid-solution EPR spectra of $1-4 d$ only show two $g$ values close to 2.0 (Figure 3, Table 3), representing an axial $g$ tensor. Whereas a fairly good resolution for the ${ }^{31} \mathrm{P}$ hfs can be observed on $g_{\|}$and on $g_{\perp}$ for $\mathbf{3 a , b}$ and $\mathbf{4 a - d}$, the ${ }^{1} \mathrm{H}$ hfs
remains unresolved in all cases. This unresolved ${ }^{1} \mathrm{H}$ hfs makes considerable contributions to the line width, preventing an accurate determination of $g_{\|}$ and $g_{\perp}$ as well as $A_{\| 1}\left({ }^{31} \mathrm{P}\right)$ and $A_{\perp}\left({ }^{31} \mathrm{P}\right)$ by the calculation of the experimental spectra. The latter would have been worthwhile for calculating the anisotropic part of the ${ }^{31} \mathrm{p}$ hfc, from which the $\pi$-electron density on the phosphorus atom could have been estimated. ${ }^{[16]}$ However, $\left.A_{\|!}{ }^{31} \mathrm{P}\right)$ and $A_{1}\left({ }^{31} \mathrm{P}\right)$ only differ to a small extent and are nearly as large as $a_{\text {iso }}\left({ }^{31} \mathrm{P}\right.$ ), indicating the same sign of $A_{\|}, A_{\perp}$, and $a_{\text {iso }}$.

[a] DME, $0.1 \mathrm{~m} \mathrm{TBAPF}_{6}$, Pt working electrode, $\mathrm{Ag} / \mathrm{Ag}^{+}$with 0.1 MAg triflate as the reference electrode. [b] $E_{\mathrm{cq}}$ (equilibrium potential), $E_{1 / 2}, E_{\mathrm{pc}}, E_{\mathrm{pa}}$ in Volts vs. $\mathrm{FcH} / \mathrm{FcH}{ }^{+}$ ( $\mathrm{FcH}=$ ferrocene), $\Delta E_{\mathrm{p}}$ in mV . [c] $\Delta E_{\mathrm{p}}$ depends on the scan rate $v$, but $E_{1 / 2}=1 / 2\left(E_{\mathrm{pc}}+E_{\mathrm{p} 2}\right.$ ) remains constant. [d] Only peak potential $E_{\mathrm{pc}}$ is given. [e] Peak current decreases with increasing scan rate. [f] Irreversible two-electron oxidation $(+1 /+3)$. [g] Poorly resolved.
-0.64 and -0.74 V vs. $\mathrm{FcH} / \mathrm{FcH}^{+}$( $\mathrm{FcH}=$ ferrocene), respectively, and two completely irreversible oxidation steps beyond 0 V .

A reduction wave $(0 /-1)$ occurs at -2 V for 1 and 2 . For 1 this is electrochemically reversible (Table 4), whereas for 2 the difference in the peak potentials $\Delta E_{\mathrm{p}}$ of the redox couple $0 /-1$ depends on the scan rate $v$; this indicates a chemically reversible reaction upon uptake of an electron. An additional couple $-1 /-2$ for 1 and 2 (not depicted) is at the potential limit of the solvent, preventing an exact determination of the ratio of the peak currents. Nevertheless, the observed independence of the peak potentials from the scan rate $v$ indicates electrochemical reversibility of the redox couple $-1 /-2$.

The features in the CV of the phosphane-containing complexes $\mathbf{3 a}, \mathbf{b}$ and $\mathbf{4 a - d}$ (Figure 4B,C) resemble those of $\mathbf{1}$ and $\mathbf{2}$. A completely irreversible oxidation step is found at about 0 V , which seems to be a two-electron transfer step for $\mathbf{3 a}, \mathbf{3 b}$, and $\mathbf{4 a}$; for $\mathbf{4 b} \mathbf{- d}$ (Figure 4C), these irreversible oxidations are resolved as two one-electron transfers. An electrochemically reversible oxidation is located near -1 V , with the exception of 4 d whose corresponding oxidation potential is shifted to -0.62 V . For $\mathbf{4 a - c}$ a reduction step $(0 /-1)$ can be recorded clearly below -2 V , near the potential limit of the solvent, while for $\mathbf{4 d}$ the first reduction occurs slightly above -2 V . However, the peak potentials depend on the scan rate; this shows that the redox couple $0 /-1$ is at least electrochemically irreversible. In cases where a reoxidation wave can be observed (e.g. $4 \mathrm{a}, 4 \mathrm{c}, 4 \mathrm{~d}$ ), $E_{1 / 2}=1 / 2\left(E_{\mathrm{pc}}+E_{\mathrm{pa}}\right)$ remains constant.

A comparison of the redox potentials of $1-4 \mathrm{c}$ shows that a distinct cathodic shift of more than 250 mV can generally be observed on going from $\mathbf{1}$ and $\mathbf{2}$ with $\mathrm{Fe}(\mathrm{CO})_{3}$ fragments to the corresponding phosphane-containing species. The redox waves for $\mathbf{4 d}$ display an anodic shift with respect to the corresponding potentials of 2 , reflecting the strong $\pi$-acidity of $\mathrm{PF}_{3}$. The change from Cp to $\mathrm{Cp}^{*}$ only causes a cathodic shift of about 100 mV for the first reversible oxidation step and of only $40-50 \mathrm{mV}$ for the first reduction step.

## Discussion

The heterodinuclear complexes of composition $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}(\mu-\right.$ $\left.\mathrm{Cot}) \mathrm{Fe}(\mathrm{CO})_{3}\right](1, \mathrm{R}=\mathrm{H} ; 2, \mathrm{R}=\mathrm{Me})$ were obtained in comparably good yields from the reaction of $\left[\left(\mathrm{CO}_{3}\right) \mathrm{Fe}(\right.$ cis cyclooctene $\left.)_{2}\right]$ with $\left[\mathrm{CpCr}\left(\eta^{6}-\mathrm{Cot}\right)\right]$ and $\left[\mathrm{Cp}^{*} \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right]$,
respectively. In spite of the bulkier $\mathrm{Cp}^{*}$ ligand in $\mathbf{2}$, both complexes have the same synfacial configuration. No indication was found for the formation of an antifacial derivative in the casc of $\mathrm{Cp}^{*}$, although it contains only one electron less than the 34 VE species, which allow both configurations. The formation of exclusively synfacial products may have two different causes:

1) The steric interactions with the permethylated cyclopentadienyl ligand in the synfacial configuration, which have been shown to give rise to distortions in the crystal structure, are not sufficient to overcome the reduction in stability on formation of antifacial species with less than 34 VE .
2) The free double bond in the starting materials $\left[\mathrm{CpCr}\left(\eta^{6}-\right.\right.$ $\mathrm{Cot})]$ and $\left[\mathrm{Cp}{ }^{*} \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right]$ is only accessible for coordination from the endo face with respect to the chromium center (Scheme 1), since the free double bond is bent away from the plane of the six metal-bound carbon atoms by about $64^{\circ}$. ${ }^{[17]}$

Scheme 1. Suggested reaction pathway of the formation of 1 and $2(\mathrm{R}=\mathrm{H}, \mathrm{Me})$.

A remarkable feature of the $\mathrm{Cp}^{*}$ complex 2 is the faster substitution of CO by phosphanes compared to the Cp derivative 1 , although one would expect a larger steric hindrance of the Cp * ligand. The acceleration of the CO substitution in $\mathbf{2}$ may be due to a weakening of the $\mathrm{Cr}-\mathrm{Fe}$ bond, reflected by the elongation of about 10 pm , which facilitates the homolysis of the metalmetal bond. The product of the homolysis would contain a 16 VE unit $\left[\mathrm{Cp}{ }^{*} \mathrm{Cr}\left(\eta^{5}-\mathrm{Cot}\right)\right]$ and a 17 VE unit $\left[(\mathrm{CO})_{3} \mathrm{Fe}\left(\eta^{3}-\right.\right.$ $\mathrm{Cot})]$ (Scheme 2a). The 17 VE allyl complex $\left[(\mathrm{CO})_{3} \mathrm{Fe}\left(\eta^{3}-\right.\right.$ $\mathrm{C}_{3} \mathrm{H}_{5}$ )] also readily undergoes CO substitution reactions with phosphanes, ${ }^{[8,9]}$ believed to involve an intermediate or transition state with 19 VE. ${ }^{[9]}$ Subsequent elimination of CO yields

Scheme 2. Suggested reaction pathways of the CO substitution reactions $(\mathrm{R}=\mathrm{H}$, Me ).
the product. An alternative route includes a change of the hapticity of the Cot ligand after $\mathrm{Cr}-\mathrm{Fe}$ bond homolysis occurs-a reversal of the formation of 1 and 2 (Scheme 2 b ; cf. Scheme 1).

The 16 VE fragment $\left[(\mathrm{CO})_{3} \mathrm{Fe}\left(\eta^{2}-\mathrm{Cot}\right)\right]$ readily coordinates to a phosphane ligand, and the products are subsequently formed by elimination of one CO. In addition, the 17 VE allylic as well as the 16 VE olefinic $\left[\mathrm{Fe}(\mathrm{CO})_{2} \mathrm{PR}_{3}^{\prime}\right]$ species can rotate around the $\eta^{3}$ - or $\eta^{2}$-carbon-metal bond, respectively, which enables the sterically more demanding $\mathrm{PR}_{3}^{\prime}$ ligand to adopt a trans arrangement. In competition to the CO elimination, the bond between the Cot ligand and $\left[\mathrm{Fe}(\mathrm{CO})_{3} \mathrm{PR}_{3}^{\prime}\right]$ may be cleaved yielding an unsaturated mononuclear species, which rapidly adds CO or $\mathrm{PR}_{3}^{\prime}$ from the reaction solution. The observed formation of $\left[\mathrm{Fe}(\mathrm{CO})_{5-x} \mathrm{~L}_{x}\right]\left(\mathrm{L}=\mathrm{PMe}_{3}\right)$ in the reaction of 1 with $\mathrm{PMe}_{3}$ confirms this possible side reaction.

In contrast to the influence of the $\mathrm{Cp}^{*}$ ligand on the $\mathrm{Cr}-\mathrm{Fe}$ bond lengths, the change of the ligands L trans to the chromium center, for example, from $1(\mathrm{~L}=\mathrm{CO})$ to $3 \mathrm{a}\left(\mathrm{L}=\mathrm{PMe}_{3}\right)$ and from $2(\mathrm{~L}=\mathrm{CO})$ to $\mathbf{4 c}\left(\mathrm{L}=\mathrm{P}(\mathrm{OEt})_{3}\right)$, does not alter the $\mathrm{Cr}-\mathrm{Fe}$ bond length significantly. This is surprising given the fact that a strong $\pi$ acceptor (CO) is substituted by a medium $\pi$ acceptor $\left(\mathrm{PMe}_{3}, \mathrm{P}(\mathrm{OEt})_{3}\right)$ and that the $\mathrm{Cr}-\mathrm{Fe}-\mathrm{L}$ unit is in an almost linear arrangement and is thus set up for a trans effect.

Although weak, the chromium-iron bonds in the dinuclear compounds under investigation are confirmed to exist by ESR spectroscopy. The most striking differences within the ESR spectra of all of the dinuclear compounds is the unexpectedly large ${ }^{31} \mathrm{P}$ hfcc of $\mathbf{3 a - 4 d}$, which roughly doubles the isotropic
his of 1 and 2 . The ${ }^{31} \mathrm{P}$ hfce are similar to ${ }^{31} \mathrm{P}$ hfcc of 17 VE half-sandwich compounds with $\mathrm{PR}_{3}^{\prime}$ ligands directly linked to the paramagnetic center, ${ }^{[20]}$ although the phosphane ligands in $\mathbf{3 a}, \mathbf{b}$ and $\mathbf{4 a - d}$ are coordinated to the iron centers and not to the paramagnetic Cr centers, as shown by X-ray structure analyses. Hence, a very effective electron spin transfer must occur from the Cr center to the P atom.

Presumably, the electron spin is transferred in two different ways (Figure 5). Firstly, the unpaired $\mathrm{Cr} \mathrm{d}_{\mathrm{z}^{2}}$-type electron induces a spin polarization of the electron pair of the $\mathrm{Cr}-\mathrm{Fe} \sigma$ bond, which causes a corresponding spin polarization of the $\mathrm{Fe}-\mathrm{P}$ bonding electrons. This polarization manifests itself in an excess of positive spin density at the ${ }^{31} \mathrm{P}$ nucleus (Figure 5A). Secondly, an electron spin delocalization may occur through orbitals of $\pi$-bonding character (Figure 5 B ). The Cr - $\mathrm{Fe}-\mathrm{P}$
A
 $d$ - $\sigma$-Spin polarization

Figure 5. Possible pathways of spin transfer from the Cr center to the P atom: A) spin $\sigma$ polarization; B) spin $\pi$ delocalization.
grouping may be regarded as a 3 -center $/ 3 \pi$-electron system with an interaction between the $\mathrm{Cr}-\mathrm{d}_{\mathrm{z}^{2}}$ orbital, a d-type orbital of the iron center, and a suitable $\sigma^{*}$ orbital of the P ligand, ${ }^{[21]}$ leading to a doubly occupied bonding, a semi-occupied nonbonding, and an empty antibonding molecular orbital. Consequently, this type of $\pi$ delocalization yields a population of positive electron spin density at the phosphorus atom, similar to that induced by the $\sigma$-spin polarization. The importance of the $\pi$-delocalization mechanism for the ${ }^{31} \mathrm{P}$ hfcc is recognized from the distinct increase of the ${ }^{31} \mathrm{P}$ hfcc with increasing $\pi$-acidity of the phospho-rus-containing ligands. ${ }^{[22]}$ The increased $\pi$-acidity is also reflected in the energy of the CO stretching vibrations (Table 1), in the change of the redox potentials (Table 4), and in the slight shortening of the $\mathrm{Fe}-\mathrm{L}$ bond in $\mathbf{4 c}$ as compared to $\mathbf{3 a}$ (Table 2).

A spin transfer through the bridging Cot ligand may be excluded from consideration. The spin transfer between the Cr and Fe center would then have to occur through the carboncarbon single bonds between $C(3)-C(4)$ and $C(6)-C(7)$, which normally lowers the spin density by an order of magnitude.

A low spin density in the distal part of a cyclo- $\mathrm{C}_{8}$ ligand, which is not coordinated to the paramagnetic center of mononuclear $\mathrm{d}^{5}$ complexes such as $\left[\mathrm{CpCr}\left(\eta^{6}-\mathrm{Cot}\right)\right]^{[7]}$ and $\left[\mathrm{CpV}\left(\eta^{7}-\right.\right.$ $\left.\left.\mathrm{C}_{8} \mathrm{H}_{9}\right)\right],{ }^{[23]}$ is indicated by $a\left({ }^{1} \mathrm{H}\right)$ hfcc of about 1 G or smaller for protons in the $\beta$-position.

In addition to the increase of the ${ }^{31} \mathrm{P}$ hfcc from 4 a to 4 d , there is a decrease of the ${ }^{1} \mathrm{H}$ hfcc of $1-\mathrm{H}$, which sits opposite the $\mathrm{PR}_{3}^{\prime}$ ligand. Interestingly, the change of the ${ }^{1} \mathrm{H}$ hfcc of $1-\mathrm{H}$ is accompanied by small, but noticeable structural changes: lengthening of the bond between Cr and $\mathrm{C}(1)$ can be observed with the decrease of the ${ }^{1} \mathrm{H}$ hfcc of $1-\mathrm{H}$ (Table 5). Apparently, an increase of the $\pi$-acidity of the phosphane ligand weakens the trans-positioned $\mathrm{Cr}-\mathrm{C}(1)$ bond. This special "long range" trans effect can only occur through a direct $\mathrm{Cr}-\mathrm{Fe}$ bond, although it is presumably a weak one.

Table 5. Selected structural and ESR spectroscopic data to indicate a "long range" trams-effect in $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{~L}\right]$.

|  | R | L | $a\left(1^{1} \mathrm{H}\right)[\mathrm{G}]$ | $a\left({ }^{3} \mathrm{P}\right)[\mathrm{G}]$ | $\\|(\mathrm{Cr}-\mathrm{C}(1))[\mathrm{pm}]$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{2}$ | Me | CO | 2.6 | - | $217.2(4)$ |
| 4 c | Me | $\mathrm{P}(\mathrm{OEt})_{3}$ | 3.4 | 23.5 | $216.5(3)$ |
| 3 a | H | $\mathrm{PMe}_{3}$ | 3.7 | 13.3 | $215.1(3)$ |

The assumption of a $\mathrm{Cr}-\mathrm{Fe}$ bond does not contradict the axial $g$ tensor found for $\mathbf{1 - 4 d}$. As already outlined, the ESR data point to a $\mathrm{d}_{\mathrm{z}^{2}}$-type SOMO, which is known to be almost nonbonding with respect to the $\pi$ ligand. Hence, changes in symmetry of the $\pi$ ligand or changes in the nature of the coordinating atoms lying in plane with the $\pi$ ligand only cause small perturbations in the symmetry of the SOMO. ${ }^{[7,24 a]}$

The population of a SOMO with a predominant $\mathrm{Cr}-\mathrm{d}_{\mathrm{z}^{2}}$ character in the heterodinuclear complexes $\mathbf{1 - 4 d}$ also agrees with the results of the CV measurements. The induced cathodic shift of 20 mV and less per methyl group, on changing from the compounds with unmethylated $\mathrm{Cp}(\mathbf{1}, \mathbf{3 a}, \mathbf{3 b})$ to the corresponding $\mathrm{Cp}^{*}$ derivatives (e.g., for the oxidation step $0 /+1$ and the reduction step $0 /-1$ ), is characteristic for sandwich-type complexes containing a SOMO with a $\mathrm{d}_{\mathbf{2}^{2}}$-type orbital that is almost nonbonding with respect to the aromatic ligand. ${ }^{[24 \mathrm{~b}, 25]}$

In contrast, the substitution of one CO by $\mathrm{PR}_{3}^{\prime}$ causes shifts in the redox potentials ranging from a 500 mV cathodic shift to a 90 mV anodic shift with respect to the potentials of the corresponding CO compounds 1 and 2 , depending on the $\pi$-acidity of $\mathrm{PR}_{3}^{\prime}$; all of the redox couples are distinctly influenced by the nature of the $\mathrm{PR}_{3}^{\prime}$ ligand. This observation is in accordance with the outlined $\sigma$ and $\pi$ interactions explaining the unexpectedly large ${ }^{31} \mathrm{P}$ hfcc obtained from ESR spectra.

Finally, it is of interest to compare the redox properties of the synfacial 33 VE complexes with those of the 34 VE antifacial complexes. The latter only show two-electron oxidations at ambient temperatures; ${ }^{[26]}$ this is accompanied by a Cot ring cleavage, after which the formation of a metal-metal bond is possible. Apparently, an antifacial configuration with 33 VE is not sufficiently stable to be recognized-at least for homodinuclear complexes-even on the electrochemical timescale.

## Summary

The reaction of $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left(\eta^{6}\right.\right.$-Cot $\left.)\right] \quad(\mathrm{R}=\mathrm{H}$, Me) with $\left[(\mathrm{CO})_{3} \mathrm{Fe}(\eta \text {-cis-cyclooctene })_{2}\right]$ yields the heterodinuclear $\mu$-Cot complexes $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}_{1}^{f}\left(\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\}_{5}^{1} \mathrm{Fe}(\mathrm{CO})_{3}\right]$ exclusively with a synfacial coordination mode, regardless of the nature of R . These complexes undergo facile thermal substitution reactions of one CO by $\mathrm{PR}_{3}^{\prime}(\mathrm{R}=\mathrm{Me}, \mathrm{Ph}, \mathrm{OEt}, \mathrm{F})$ to produce $\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left\{\left(\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}{ }_{\}}^{\prime} \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{PR}_{3}^{\prime}\right]\right.\right.$. X-ray structure analyses indicate the presence of a long $\mathrm{Cr}-\mathrm{Fe}$ single bond, which stretches by about 10 pm when the Cp ligand is replaced by the sterically demanding $\mathrm{Cp} *$ ligand. ESR spectroscopic studies reveal surprisingly high ${ }^{31} \mathrm{P}$ hfcc. These are explained by two different spin transfer mechanisms based on $\sigma$ and $\pi$-bonding interactions of the trinuclear $\mathrm{Cr}-\mathrm{Fe}-\mathrm{P}$ group and confirm the presence of a direct $\mathrm{Cr}-\mathrm{Fe}$ bond. These bonding interactions also explain the dependence of the redox potentials on the $\pi$-accepting ability of the trans ligand at the Fe center.

## Experimental Section

All manipulations were carried out under an $\mathrm{N}_{2}$ atmosphere and in solvents saturated with $\mathrm{N}_{2}$. Tetrahydrofuran (THF) and 2-methyltetrahydrofuran (MTHF) were freshly distilled from potassium metal/benzophenone; $n$-hexane was distilled from $\mathrm{K} / \mathrm{Na}$ alloy, toluene from Na . IR : THF solutions were measured against pure THF, when not otherwise stated, KBr cells, FT-IR 1720X (Perkin Elmer). Cyclic voltammetry: DME, $0.1 \mathrm{M}(n \mathrm{Bu})_{4} \mathrm{NPF}_{6}$ $\left(\mathrm{TBAPF}_{6}\right.$ ), Pt working electrode (disk, $\varnothing 3 \mathrm{~mm}$ ), Pt wire as an auxilliary electrode, $\mathrm{Ag} / 0.1 \mathrm{~m}$ silver triflate as a reference electrode, PAR 273 potentiostat (E \& EG). ESR: MTHF solutions, ESP 300 (Bruker); the recorded spectra were simulated with the software program simphonia (Bruker). EI-MS: 70 eV , Finnigan MAT311A. Elemental analysis: Heraeus CHN-ORapid, Institut für Anorganische und Angewandte Chemie, Universität Hamburg. $\left[\mathrm{CpCr}\left(\eta^{6}-\mathrm{Cot}\right)\right]{ }^{[7]} \quad\left[\mathrm{Cp} * \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right]^{[7]}$ and $\left[(\mathrm{CO})_{3} \mathrm{Fe}(\eta-\right.$-ciscyclooctene $)_{2}{ }^{[8]}$ were synthesized according to the literature. $\mathrm{PF}_{3}$ was kindly donated by Prof. Kruck, Institut für Anorganische Chemie, Univer. sität Köln.
$\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{3}\right](1)$ : A mixture of $\left[\mathrm{CpCr}\left(\eta^{6}-\mathrm{Cot}\right)\right]$ $(0.86 \mathrm{~g}, 3.11 \mathrm{mmol})$ and $\left[(\mathrm{CO})_{3} \mathrm{Fe}(\eta\right.$-cis-cyclooctene $\left.)\right](1.12 \mathrm{~g}, 3.11 \mathrm{mmol})$ in pentane was stirred for 2 h at $-78^{\circ} \mathrm{C}$. The reaction mixture was allowed to warm to room temperature and filtered through a short plug of celite. The solvent was concentrated until crystallization started. After storage at $-30^{\wedge} \mathrm{C}$ for $2 \mathrm{~d}, 0.91 \mathrm{~g}(81 \%)$ of 1 was obtained.
$\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{3}\right\rfloor$ (2): The synthesis was performed as for 1 . $\left[\mathrm{Cp}^{*} \mathrm{Cr}\left(\eta^{6}-\mathrm{Cot}\right)\right](2.04 \mathrm{~g}, 7.0 \mathrm{mmol})$ and $\left[(\mathrm{CO})_{3} \mathrm{Fe}(\right.$ cis-cyclooctene $\left.)_{2}\right](2.17 \mathrm{~g}, 7.0 \mathrm{mmol})$ were reacted at $-78^{\circ} \mathrm{C}$ for 3 h to yield 2.56 g $(85 \%)$ of 2. M.p. $139^{\circ} \mathrm{C}$ (in closed capillary); IR (nujol): $\tilde{v}=2002$, $1931 \mathrm{~cm}^{-1} ;$ EI-MS: $m / z(\%)=431$ ( 0.01 ) $\left[M^{+}\right], 403(16)\left[M^{+}-\mathrm{CO}\right]$, 375 (17) $\left[M^{+}-2 \mathrm{CO}\right], 347$ (100) [ $\left.M^{+}-3 \mathrm{CO}\right], 319$ (36), 291 (78) $\left[\left(\mathrm{Cp}^{*} \mathrm{CrCot}\right)^{+}\right], 276(21), 251(11), 187(88)\left[(\mathrm{Cp} * \mathrm{Cr})^{+}\right], 133$ (21), 91 (3) $\left[\left(\mathrm{C}_{7} \mathrm{H}_{7}\right)^{+}\right], 52(47)\left[\mathrm{Cr}^{+}\right] ; \mathrm{C}_{21} \mathrm{H}_{23} \mathrm{CrFeO}_{3}$ (427.3); calcd C 58.49, H 5.38; found C $58 \cdot 53$, H 5.26 .
$\left[\left(\mathrm{C}_{5} \mathrm{R}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{PR}_{3}^{\prime}\right](3 \mathrm{a}-4 \mathrm{c})$ : In a typical reaction an equimolar amount of $\mathrm{PR}_{3}^{\prime}$ and 1 or 2 were stirred at room temperature. The scope of the reaction was monitored by IR spectroscopy. During the reaction additional $\mathrm{PR}_{3}^{\prime}\left(\mathrm{R}^{\prime}=\mathrm{Me}, \mathrm{Ph}\right)$ was added periodically until the $v(\mathrm{CO})$ bands of the starting material had disappeared. The solvent was removed in vacuo and the residue was extracted with $n$-hexane. The hexane extract was filtered through celite and reduced until a crystalline material precipitated. After storage of this solution at $-30^{\circ} \mathrm{C}$ for 2 d , the product was obtained as a brownish black crystalline material. It is very sensitive to oxygen in solution. See Table 6 for quantities used, reaction time and yields.

$\mathrm{C}_{26} \mathrm{H}_{38} \mathrm{CrFeO}_{5} \mathrm{P}$ ( 569.41 ): caled C 54.84, H 6.73 ; found $\mathrm{C} 54.60, \mathrm{H} 6.65$.
$\mathrm{I}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Cr}\left\{\mu-\eta^{5}(\mathrm{Cr}): \eta^{3}(\mathrm{Fe})-\mathrm{Cot}\right\} \mathrm{Fe}(\mathrm{CO})_{2} \mathrm{PF}_{3} \mid(4 \mathrm{~d}): \mathrm{PF}_{3}$ was slowly passed through a capillary into the reaction vessel, which was secured by a valve that prevented the entry of air, and released the overpressure in the reaction vessel. Unreacted $\mathrm{PF}_{3}$ was destroyed by bubbling it through concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$. IR spectra were recorded periodically to monitor the progress of the reaction. After 3 h no $\tilde{v}(\mathrm{CO})$ bands of the starting material 2 could be recorded (workup procedure, vide supra). EI-MS: m/z (\%): $491(0.6)\left[M^{+}\right], 463(0.2)$ [ $\left.M^{+}-\mathrm{CO}\right], 403$ (6) $\left[M^{+}-\mathrm{PF}_{3}\right], 375$ (7) $\left[M^{+}-\mathrm{PF}_{3}-\mathrm{CO}\right] .347$ (40) $\left[M^{+}-\mathrm{PF}_{3}-2 \mathrm{CO}\right], 291(59)\left[\left(\mathrm{Cp}^{*} \mathrm{CrCot}\right)^{+}\right], 187(100)\left[\left(\mathrm{Cp}{ }^{*} \mathrm{Cr}\right)^{+}\right], 133$ (30), $119(28), 104(24)\left[\mathrm{Cot}^{+}\right], 88(29)\left[\left(\mathrm{PF}_{3}\right)^{+}\right], 78(20), 69(30)\left[\left(\mathrm{PF}_{2}\right)^{+}\right]$, 52 (86) [Cr $\left.{ }^{+}\right] ; \mathrm{C}_{20} \mathrm{H}_{23} \mathrm{CrFF}_{3} \mathrm{FeO}_{2} \mathrm{P}$ (491.22); calcd C 48.90, H 4.72, found C 48.32 , H 4.80 .

Crystal Structure Analyses: The measurements were performed in a Hilger \& Watts ( Y 290 ), applying monochromatic $\mathrm{Mo}_{\mathrm{K} x}$ radiation. The heavy atoms were found by direct methods using SHELXS 86. ${ }^{[27]}$ The structures were refined using SHELXL $92{ }^{[28]}$ or SHELXL $93 .{ }^{[24]}$ See Table 7 for more details concerning the crystal data and data collection. ${ }^{[30]}$
