Abstract

The objective of this analysis was to evaluate the change over time in age at first symptoms, age at diagnosis, and delay in diagnosis using data from the Icatibant Outcome Survey (IOS). Patients with a diagnosis of C1-INH-HAE who were born before the year 1990 and who were diagnosed before they reached 25 years of age were included in the analysis. Both age at diagnosis and delay in diagnosis of C1-INH-HAE appear to decline with later decade of birth, despite wide variation across the countries assessed, suggesting that improved disease awareness causes increased rates of earlier diagnosis over time. Our findings demonstrate that some patients are still experiencing long delays to diagnosis, indicating an ongoing need for improved disease awareness.

Keywords: Hereditary angioedema, HAE, C1-INH-HAE, Diagnosis, Delay in diagnosis

To the Editor,

Hereditary angioedema due to C1 inhibitor deficiency or dysfunction (type I or type II; C1-INH-HAE) is a rare genetic disease characterized by repeated episodes of bradykinin-mediated swelling in subcutaneous or submucosal tissues [1, 2]. C1-INH-HAE is often poorly recognized because of its nonspecific signs and symptoms. As a result, misdiagnoses and delays in obtaining a correct diagnosis are common [3, 4]. The impact of a late diagnosis can be high, as initiation of appropriate therapy is delayed, putting patients at increased risk of morbidity and mortality [4, 5] and leading to unnecessary medical or surgical procedures [6]. Given the young age of patients at symptom onset, a delayed diagnosis may cause disruption of education or early working life, and

significantly impacts quality of life and social involvement [7, 8]. Although awareness of C1-INH-HAE has improved over recent decades, it is not clear if this has translated into earlier diagnosis. Here, we evaluated the change in age at first symptoms, age at diagnosis, and delay in diagnosis by decade of birth in patients with C1-INH-HAE enrolled in the Icatibant Outcome Survey (IOS). IOS is an ongoing, international, multicenter, prospective, observational study (NCT01034969) designed to monitor the safety and effectiveness of icatibant, a bradykinin B₂ receptor antagonist [9].

As of January 2017, 11 countries (Austria, Brazil, Czech Republic, Denmark, France, Germany, Greece, Israel, Italy, Spain, and the United Kingdom) were involved in the registry. Participation is voluntary, at the discretion of the physician and the patient, and patients are managed under the direction of their physician in accordance with routine clinical practice. Patient data, including year of birth, age at diagnosis, and delay between symptom onset and diagnosis, are collected by physicians using a web-based

electronic case report form at the time of enrollment, and during subsequent routine examinations or visits to manage angioedema attacks. Written informed consent is obtained from all patients prior to enrollment in IOS. IOS is conducted in accordance with the Declaration of Helsinki and the International Conference on Harmonization Good Clinical Practice Guidelines, and with approval from local ethics committees and/or health authorities.

This analysis included patients with C1-INH-HAE who were born before 1990 and diagnosed before the age of 25 years. Patients diagnosed before the onset of symptoms, owing to a family history of C1-INH-HAE, were excluded. Data were collected from July 2009 through January 2017. Owing to the observational nature of the registry, all analyses were considered exploratory and no adjustment for multiplicity was performed. Linear regression analyses were performed to determine the correlation between time to event parameters and decade of birth, with a statistical significance level of $\alpha = 0.05$.

As of January 2017, 250 patients with C1-INH-HAE type I ($n = 240$) or type II ($n = 10$) enrolled in IOS met the inclusion criteria. Of these, 139 (55.6%) were female. Median age at onset of symptoms was 9.0 years (interquartile range [IQR]: 4.0–16.0 years), median age at diagnosis was 16.7 years (IQR: 10.1–19.8 years), and median delay in diagnosis was 2.6 years (IQR: 0.1–9.7 years; Fig. 1a–c). There was considerable variation among countries, with median age at onset of symptoms ranging from 0.5 to 12.0 years, median age at diagnosis ranging from 13.5 to 22.3 years, and median delay in diagnosis ranging from 0.13 to 17.3 years (Fig. 1a–c).

Using linear regression analysis, we found that age at diagnosis and delay in diagnosis both declined with later decade of birth ($p \leq 0.0001$, Pearson correlation coefficient $r = -0.2659$; and $p = 0.0029$, $r = -0.1874$, respectively). Patients born during 1950–1960 ($n = 24$) were diagnosed at a median age of 20.2 years compared with 15.4 years for those born during 1980–1990 ($n = 94$), whereas patients born during 1950–1960 experienced a delay in diagnosis of 7.0 years compared with 1.4 years for those born during 1980–1990. Age at symptom onset remained unchanged irrespective of decade of birth (Fig. 2a–c). Patients with a family history of C1-INH-HAE ($n = 180$; 72.0%) had a median delay in diagnosis of 2.0 years compared with 5.6 years for those with no or unknown family history ($p = 0.0092$).

Our findings demonstrate improvements in C1-INH-HAE diagnosis over time, with patients now more frequently being diagnosed at a younger age, and with shorter delays between symptom onset and diagnosis. However, patients diagnosed prior to symptom onset were excluded from this analysis, precluding the evaluation of diagnosis rates for those with a family history of HAE. Though data from registries such as IOS provide a valuable source of real-world information, the voluntary nature of participation presents a number of limitations, including missing or incomplete data and potential selection bias. Almost two-thirds of patients included in this analysis were born between 1970 and 1990, suggestive of a potential bias towards recently diagnosed patients. Of note, some patients are still experiencing long delays to diagnosis, indicating an ongoing need for improved disease awareness.

Acknowledgements

Under the direction of the authors, Lindsay Napier, Ph.D., and Sally Hassan, Ph.D., employees of Excel Medical Affairs, provided writing assistance for this publication. Editorial assistance in formatting, proofreading, copy editing, and fact checking also was provided by Excel Medical Affairs. Shire HGT provided funding to Excel Medical Affairs for support in writing and editing this manuscript. The interpretation of the data was made by the authors independently.

Competing interests

AZ has received speaker fees from CSL Behring, Shire, and Sobi; consulting fees from CSL Behring and Shire; and has acted on medical/advisory boards for CSL Behring and Shire. MM has received consulting fees and payment for lectures from BioCryst, CSL Behring, Shire, and Sobi; and has received research grants from Shire. HJL has received research grant support and/or speaker/consulting fees from Adverum, BioCryst, CSL Behring, Pharming, and Shire. WA has acted as medical advisor/speaker for BioCryst, CSL Behring, Pharming, and Shire; and has received funding to attend conferences/educational events, and donations to his departmental fund from and participated in clinical trials for Shire. TC has received speaker fees from CSL Behring, Novartis, and Shire; consulting fees from BioCryst, CSL Behring, Novartis, Octapharma, Shire, and Sobi; funding for travel/meeting attendance from CSL Behring, Novartis, and Shire; and has participated in clinical trials/registries for CSL Behring, Novartis, Pharming, and Shire. She is a researcher from the IdiPaz program for promoting research activities. LB has received honoraria from BioCryst, CSL Behring, Novartis, Pharming, and Shire; and her institute has received research funding from CSL Behring, GlaxoSmithKline, Novartis, Roche, and Shire. AB has received research grant support and/or speaker/consulting fees from CSL Behring, and Shire/Jerini AG; and participated in a clinical trial for BioCryst and Jerini AG. She is an advisor for the HAE Scandinavian Patient Organization. ASG has been a speaker/consultant for Baxalta/Shire, BioCryst, and CSL Behring. JB and IA are full-time employees of Shire, Zug, Switzerland. MM has received research grant support and/or speaker/consulting fees from BioCryst, CSL Behring, and Shire/Jerini AG.

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Consent to publish

Patients were told that their de-identified data from IOS may be used in the development of additional scientific research or publications.

Ethics, consent and permissions

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Funding

IOS is supported by Shire GmbH, Zug, Switzerland.

Informed consent

Informed consent was obtained from all individual participants included in the IOS.
