Psychosocial and stress-related aspects on Ischemic Heart Disease

Akademisk avhandling
som för avläggande av medicine doktorsexamen vid Sahlgrenska Akademin vid Göteborgs universitet kommer att offentligen försvaras i hörsal Inge Schiöler, Medicinaregatan 11, Göteborg, fredagen den 10 juni 2011 klockan 09.00,

av
Inger Bengtsson
MD, MScPH

Fakultetsopponent:
Professor Margareta Kristenson
Avdelningen för samhällsmedicine, socialmedicine och folkhälsovietenskap
Institutionen för medicine och hälsa
Linköpings universitet

Avhandlingen baseras på följande arbeten:

Abstract

**Objective:** To study different aspects of ischemic heart disease (IHD) i.e. stress related risk factors, biochemical markers of stress, in particular the cortisol awakening response (CAR) and outcome in terms of health related quality of life (HRQoL).

**Methods:** 72 myocardial infarction (AMI) patients took part in the HRQoL studies. From a subsample of a population-based cohort of Swedish adults 194 men and women, 15% with the metabolic syndrome (MetS), took part in awakening cortisol sampling. The risk factor study was conducted on 290 previous chest pain patients. Assessment of HRQoL was via questionnaires (SF-36, CHP, Zung). CAR was performed by measuring salivary cortisol and medical records or death certificates were read identifying ischemic heart or cerebrovascular disease during 14-years of follow-up.

**Results:** Patients < 59 years improved in SF-36 Physical Component scores (PCS) but not in Mental Component scores (MCS), and scored significantly below community norms in both PCS ($\overline{x}$=44.7, CI 40.6–48.7 vs. $\overline{x}$=50.3, CI 49.3–51.4) and MCS ($\overline{x}$=45.9, CI 41.8–49.9 vs. $\overline{x}$=51.3, CI 50.3–52.4) at 6 months. Predictors for MCS were age ($p=0.03$) and Vitality ($p=0.02$). Predictors for PCS were Physical Function ($p=0.01$) and CCS angina scores ($p < 0.001$). Angina was negatively related to HRQoL. Patients < 59 years reached community norms in PCS after 2 years but scored significantly below norms in MCS throughout with an effect size of -0.5 (CI -0.88 to -0.14) at 2 years. In patients ≥ 59 years, no changes took place after 6 months. A significant difference in CAR% was found between men and women with MetS, ($\pm$SE) = 38.5 (13.1)% and 91.4 (17.0)% ($p=0.02$). Women with the MetS awoke with the lowest cortisol level ($\pm$ SE) = 8.92 (0.96) nmol.L$^{-1}$. Women without MetS had a CAR% of 36.5 (5.7)% and a awakening cortisol level of 12.33 (0.69) nmol.L$^{-1}$. The values for men were 38.5 (13.1)% and 36.0 (6.1)%.

**Conclusion:** Inferior health in younger compared to older AMI patients in mental health domains of HRQoL was detected as was a sex difference in the cortisol awakening response between men and women with MetS. Traditional risk factors were found to predict future diagnosis of ischemic heart or cerebrovascular disease 14 years after a hospital visit for chest pain.

Key-words: Ischemic heart disease, risk factors, stress, cortisol awakening response, HRQoL
