To evaluate the effect of two breeds (Belgian Blue vs. Limousin) and previous storage time and temperature on color and lipid stability of meat packaged in high-oxygen atmosphere.

INTRODUCTION

The shelf life of fresh meat is mainly limited by the development of pathogenic or spoilage microorganisms, and/or the oxidation of some of its constituents. In order to limit these phenomena, the European legislation allows chilling or freezing, eventually combined with vacuum or modified atmosphere packaging.

The oxidation of myoglobin turns this pigment to metmyoglobin, which gives a brown color to meat. Lipid oxidation results in formation of aldehydes, some of them being often associated with the development of off-flavors even at low concentrations. Myoglobin and lipid oxidation often appear to be linked.

The Belgian meat sector often complains of a sensitivity of Belgian Blue (BB) beef to oxidation processes, in particular in high-oxygen modified atmosphere packaged (MAP) meat previously aged in vacuum conditions.

RESULTS AND DISCUSSION

No significant change in metmyoglobin % was observed during vacuum storage. Belgian Blue samples under modified atmosphere tended to present a higher metmyoglobin stability until 40 days of previous storage under vacuum.

VP storage at −1 °C provided the best conditions for lipid stability. Repackaging under modified atmosphere brought out and effect of previous storage time under vacuum.

Positive correlation established between metmyoglobin % and TBARS suggesting an eventual link between myoglobin oxidation and lipid oxidation.

The higher amount of fat in meat from Limousin (4.6 ± 0.6 % vs. 1.4 ± 0.7 % in meat from Belgian Blue) could partially explain its sensitivity to oxidation.

CONCLUSIONS

The Limousin meat samples of this study presented a higher sensitivity to myoglobin and lipid oxidation, possibly due to its higher fat content. The duration and temperature of VP storage seemed to influence the sensitivity of samples to pigment and lipid oxidation during subsequent MAP storage.

Lipid and myoglobin oxidation appear to be linked. An understanding of the oxidative processes and their interaction would provide basis for explaining quality deterioration in meat and also for developing strategies (e.g. antioxidant supplementation) to maintain sensory quality.
