

# Social mobility has increased in past decades, but there has been no 'revolution' in opportunity

<http://blogs.lse.ac.uk/politicsandpolicy/2011/03/24/social-mobility-recent-decades-uk/?pfstyle=w p>

March 25, 2011

*Many commentators are deeply concerned that the government's current programme of austerity cuts will promote inequality and hurt social mobility. But how much do we really know about social mobility in the past 20 years? [Gavin Kelly](#) of the Resolution Foundation looks at new research which finds that some important, if modest, gains have been made that, while not exactly leading to an opportunity revolution, provide a welcome tonic to the conventional pessimism that characterises the mainstream discourse.*

We all know the usual story on social mobility. It's been falling steadily for several decades and continued to fall during the Labour years. Plenty of politicians, journalists and pundits will line up to tell anyone willing to listen that things have got worse. It sounds like a compelling story, but the problem is, it's not clear that it's true. While studies which look at people born before the 1970s do show a fall in social mobility across the generations, subsequent generations may have actually made modest gains and moved upwards, at least from the bottom to the middle.

To understand social mobility better, we need to differentiate between its two different types. The most common, and the one that gets by far the most attention, concerns the extent to which your parents determine your life chances (termed *inter-generational* mobility by the wonks). On this measure it's true that studies published during the 2000s showed a fall in social mobility – but those studies compared a cohort born in 1958 with one born in 1970.

Now there are quite a few possible explanations for the fall in mobility between those two groups. Most concern the nature of British society in the 1960s and 1970s compared to the 1970s and 1980s. Many experts highlight the impact of the rapid expansion of university education for the middle-classes, while many pundits point to the decline of grammar schools (a view contradicted by recent [research](#)). What all these explanations have in common is that they don't have much to do with Tony Blair or Gordon Brown, or anything else going on in Britain in the 2000s.

The truth is, we know much less about what has happened to social mobility of those born *since* the 1970s, not least because the key study that would have helped shed light on this was cancelled by Margaret Thatcher in 1980 (a mistake that [David Willetts](#) has ensured this government won't repeat). We won't get definitive evidence of what really happened to mobility in the Labour years until 2020 when the real 'Blair-babe' generation matures into adults.

For now, the best we can do on *intergenerational* mobility is try to discern likely future trends by looking at the link between parental background and the performance of children around the Millennium (using early test results at school). All in all, we can be pretty confident that mobility between generations in the UK – even if it has stopped falling – is still depressingly low, as it tends to be in highly unequal societies.

But that all brings us onto the second definition of social mobility, and here there's more light to shed. It considers the extent to which people can climb the earnings ladder within their own lifetimes (it's termed *intra-generational* mobility). It asks whether people get stuck at the same point in the earnings distribution throughout their career, or whether they can earn their way up relative to their peers.

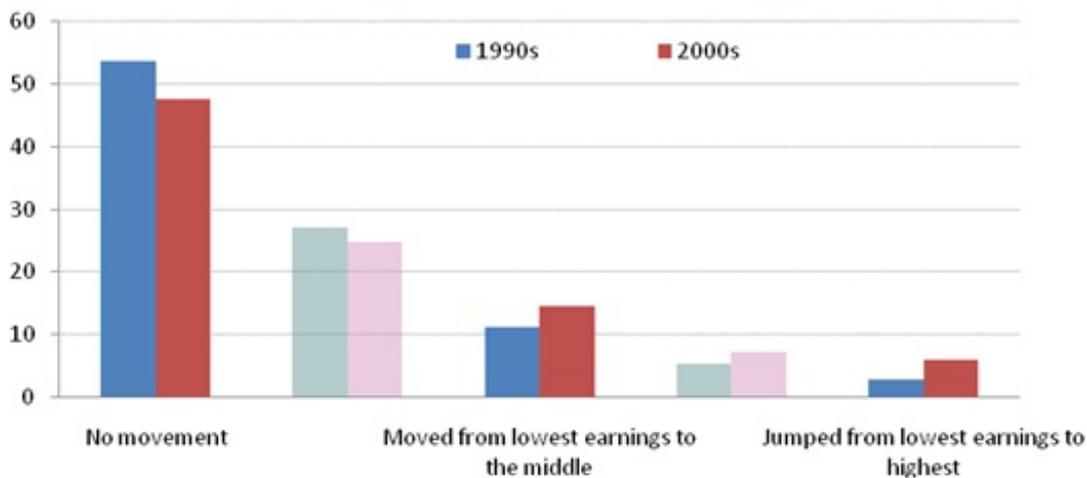

This type of mobility is almost entirely ignored in the political debate. Only a handful of academics have looked into it. Yet it, too, is fundamental to the character of our society. For many people – those living on low-to-middle incomes in particular – being able to work your way up in society is of great economic, social and psychological importance. And an economy in which those who start their careers on a high wage always stay at the top – regardless of performance – isn't going to be

either fair or efficient.

So what has happened to this type of mobility? A [major new study](#) published by Lee Savage at the [Resolution Foundation](#) tells us what changed in *intra-generational* mobility in the 2000s compared to the 1990s. It tracks a large number of people in their 30s through the 1990s and compares how socially mobile this group was compared to another group in their 30s during the 2000s.

The results are fascinating. The good news – and there is more of it than you might expect – is that the chances of someone moving a long way up the earnings distribution – enough to really change a person’s standard of living – increased by over 20 per cent in the 2000s compared to the 1990s. More interesting still, is the change in mobility across the earnings distribution. As the first chart below shows, when we look at the position of the lowest earners in society we see a small fall in the proportion who stayed at the bottom of the wage pile throughout the 2000s; a sizeable increase (31 per cent) in those who moved up from the bottom to the middle; and a doubling in the proportion who leaped right up to the top.

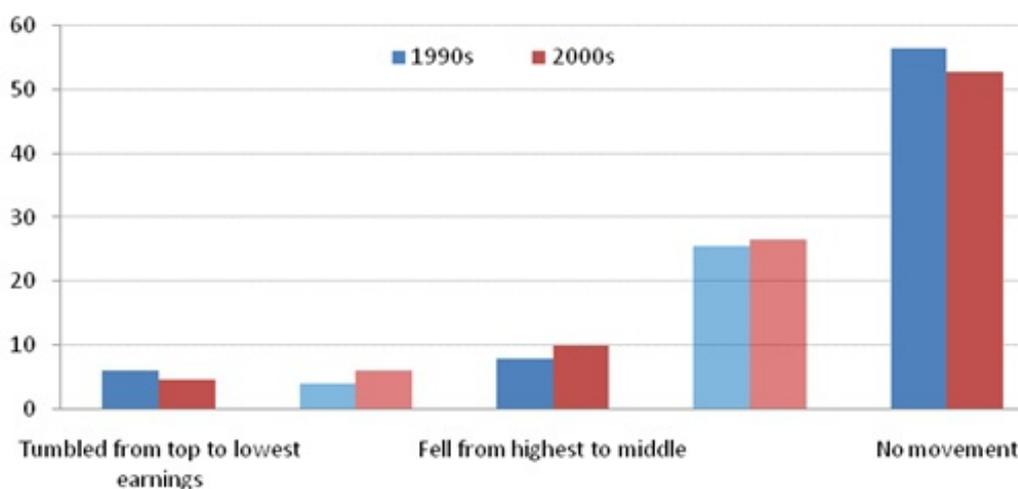

What happened to the lowest earners? (%)

Of course, upwards mobility requires downward mobility. So when we look at the richest 20 per cent of wage-earners (chart below), it’s significant that we see a small fall between the 1990s and the 2000s in the proportion who started the decade at the top

and stayed there.

What happened to highest earners (%)

So much for the good news. Most people looking at these charts will, of course, notice something rather bleaker. The over-riding story remains that, regardless of whether you were in the 1990s or 2000s generation, if

you started off at the top of the earnings distribution you were much more likely to stay there than move somewhere else. And if you started off at the bottom you were likely to stay there too. Mobility may have picked up, but from a very low-base. The doubling of the chance of moving from the bottom to the top in the 2000s loses much of its gloss when you realise that the absolute increase

was from a measly 3 per cent to 6 per cent. So, all in all, some important if modest gains – certainly enough to confound the story of the social mobility pessimists who say things only ever get worse – but not exactly a revolution in opportunity.
