Varieties of Capitalism and Institutional Complementarities in the Political Economy: An Empirical Analysis

Peter A. Hall and Daniel W. Gingerich

Abstract

This article provides a statistical analysis of the core contentions of the 'varieties of capitalism' perspective on comparative capitalism. We construct indices to assess whether patterns of coordination in the OECD economies conform to the predictions of the theory and compare the correspondence of institutions across sub-spheres of the political economy. We test the contention that institutional complementarities can occur across these sub-spheres by estimating the impact of complementarities in labor relations and corporate governance on rates of growth. To assess the durability of varieties of capitalism, we report the extent of institutional change in the 1980s and 1990s. The evidence suggests powerful interaction effects across institutions in the sub-spheres of the political economy that must be considered if efforts to assess the economic impact of institutional reform in any one sphere are to be accurate.

Varieties of Capitalism and Institutional Complementarities in the Political Economy: An Empirical Analysis

Peter A. Hall and Daniel W. Gingerich*

The field of comparative political economy has been interested for many years in understanding how differences in the organization of national political economies condition aggregate economic performance. Behind such inquiries lies the intuition that more than one economic model can deliver economic success. But what are the central features that distinguish the operation of one political economy from another, and how should countries be categorized along these dimensions of difference?

For the developed economies, the answers usually given to these questions in each era have corresponded to the principal challenges confronting those economies. During the 1960s, when economic modernization was high on the agenda, efforts to identify distinctive types of capitalism emphasized variation in the character of state intervention into the economy.¹ When inflation rose to new heights during the 1970s, the emphasis shifted to the contributions of neo-corporatism to wage and price moderation.² In recent years, scholars have been seeking approaches salient to an era of globalization.³

The object of this analysis is to subject one of the most prominent of these new approaches to a set of empirical tests. We focus on the ‘varieties of capitalism’ perspective introduced in a volume edited by Hall and Soskice and now widely referenced in the literature.⁴ Applying the new economics of organization to the macroeconomy, this approach distinguishes among capitalist economies by reference to the ways firms and other actors coordinate their endeavours. It suggests that nations cluster into identifiable groups based on the extent to which firms rely on market or strategic modes of coordination. From these formulations follow many

important contentions about variations in economic performance, comparative institutional advantage, national responses to globalization, and comparative public policy.

The varieties of capitalism approach is grounded in a rich set of comparative case-studies, but efforts to assess it using statistical analysis on larger numbers of cases are still at an early stage.⁵ Those efforts have been limited partly because we do not yet have good measures for the character of coordination, the concept at the heart of the analysis. As a result, the position of many countries within those categories remains ambiguous. We seek indicators for coordination that will allow us to test some basic tenets of this approach and that others can use for subsequent assessments.

We are especially interested in one of the core contentions of the varieties of capitalism approach, namely, its theory of *institutional complementarities* in the macroeconomy. One set of institutions is said to be complementary to another when its presence raises the returns available from the other. Economists have identified such complementarities at the level of the firm, where marketing strategies based on customized products, for instance, may be complementary to computer-controlled production processes.⁶ However, Hall and Soskice argue that complementarities, with positive effects on aggregate economic performance, are embedded in institutions across sub-spheres of the political economy.⁷ This is an important contention. If correct, it implies that efforts to reform one sphere of the political economy may yield negative economic results if unaccompanied by parallel reforms in other spheres. It predicts a particular politics of institutional defence.

By subjecting that contention to empirical assessment, we bring together issues typically treated by quite separate literatures. One considers the impact of institutional reform in labour markets, while another considers reform in corporate governance.⁸ However, there is growing evidence of interactions across some spheres of the political economy.⁹ We ask whether the

interaction effects postulated by the varieties of capitalism approach can be found across the spheres of labour relations and corporate governance.

We begin by developing indices to measure the character of coordination in labour relations and corporate governance. We then use these measures to assess the plausibility of the logic used by varieties of capitalism analysts to differentiate among developed political economies and the appropriateness of its categories. Turning to the theory's core postulates about the presence of institutional complementarities in the macroeconomy, we ask whether the institutional arrangements it sees as complementary actually yield higher rates of economic growth. Finally, we inquire into the durability of the categories generated by the varieties of capitalism literature, by examining patterns of institutional change over the past two decades. Before taking up its core propositions, however, we open with an overview of the varieties-of-capitalism perspective.¹⁰

1. The Varieties of Capitalism Approach

In contrast to the literature focused on national labour movements, varieties-of- capitalism analyses assume that firms are the central actors in the economy whose behaviour aggregates into national economic performance. In order to prosper, firms must engage with other actors in multiple spheres of the political economy: to raise finance (on financial markets), to regulate wages and working conditions (industrial relations), to ensure workers have the requisite skills (education and training), to secure access to inputs and technology (via inter-firm relations), to compete for customers (in product markets), and to secure the cooperation of their workforce (firm-employee relations). Adopting a relational view of the firm, this perspective assumes that success in each of these endeavours depends on efficient coordination with other actors. The central problems facing firms are, therefore, coordination problems.

The varieties of capitalism approach draws a distinction between two modes of coordination. In one, firms coordinate with other actors primarily through competitive markets, characterized by arms-length relations and formal contracting. Here, equilibrium outcomes are dictated primarily by relative prices, market signals, and familiar marginalist considerations. In the second, firms coordinate with other actors through processes of strategic interaction of the kind typically modeled by game theory. Here, equilibrium outcomes depend on the institutional support available for the formation of credible commitments, including support for effective information sharing, monitoring, sanctioning, and deliberation.¹¹

Although instances of market and strategic coordination occur in all capitalist economies, this approach contends that, in the spheres central to firm endeavour, the balance between these two types of coordination varies across political economies. At one end of the spectrum stand *liberal market economies* (LMEs) where relations between firms and other actors are coordinated primarily by competitive markets. At the other end are *coordinated market economies* (CMEs) where firms typically engage in more strategic interaction with trade unions, suppliers of finance, and other actors.¹²

Whether a firm coordinates its endeavours through market relations or strategic interaction is said to depend on the institutional setting. Where markets are imperfect and there is substantial institutional support for the formation of credible commitments, firms can be expected to rely more extensively on strategic coordination. Where markets are fluid and there is little support for such commitments, firms will rely more heavily on market coordination. Accordingly there should be a correspondence between the institutional configuration of each sphere of the economy and the character of coordination there.¹³

The distinction will be clearer if we describe a liberal and coordinated market economy. Market coordination is a familiar concept in neo-classical economics, and the United States is a typical liberal market economy. Here, firms face large equity markets marked by high levels of

transparency and dispersed shareholding, where firms' access to external finance depends heavily on publicly assessable criteria such as market valuation. Regulatory regimes allow hostile takeovers that depend on share price, rendering managers sensitive to current profitability. Because trade unions are relatively weak and employment protection low, labour markets are fluid and wage setting primarily a matter of contract between workers and individual employers. Because labour markets are fluid, workers have incentives to invest in general skills that can be taken to other jobs, and, because industry associations are weak, firms lack the capacity to mount the collaborative training programs that confer industry-specific skills. Technology transfer is accomplished primarily by licensing or taking on expert personnel, and standards are usually set by market races. Top managers enjoy substantial authority over all aspects of firm strategy, including lay-offs. In such settings, many of the relationships firms form with other actors are mediated by competitive markets. Although there are variations among them, the United Kingdom, Ireland, Canada, Australia and New Zealand are also generally identified as liberal market economies.

Germany provides a good example of a coordinated market economy. Its firms are closely connected by dense networks of cross-shareholding and influential employers associations. These networks provide for exchanges of private information, allowing firms to develop reputations that permit some access to capital on terms that depend more heavily on reputation than share value. Accordingly, managers are less sensitive to current profitability. In the presence of strong trade unions, powerful works councils, and high levels of employment protection, labour markets are less fluid and job tenures longer. In most industries, wage setting is coordinated by trade unions and employers associations that also supervise collaborative training schemes, providing workers with industry-specific skills and assurances of positions if they invest in them. Industry associations play a major role in standard setting, and substantial amounts of technology transfer take place through inter-firm collaboration. Hemmed in by

powerful workforce representatives and business networks, top managers have less scope for unilateral action, and firms typically adhere to more consensual styles of decision-making. It should be apparent that, in order to perform their core functions, firms in coordinated market economies like that of Germany must engage in strategic interaction in multiple spheres, although the institutions on which they rely and the quality of the outcomes may vary from one country to another. Austria, Japan, South Korea, Sweden, Norway, Finland, Denmark, Belgium, the Netherlands, and Switzerland are usually identified as coordinated market economies.

2. Establishing Coordination as a Crucial Dimension

We begin our analysis by examining the core contention of the varieties of capitalism approach that the developed economies differ from one another according to the extent to which firms depend on market or strategic coordination to accomplish their endeavours. Of course, the character of coordination is difficult to measure directly. However, as Hall and Soskice point out, the nature of coordination depends on the type of institutions available to support it.

Accordingly, a factor analysis designed to identify commonalities that may be unobservable in themselves but that correlate with a range of observable variables provides an appropriate technique for identifying the character of coordination.¹⁴ By performing a factor analysis on a set of institutional measures that are commonly associated with one type of coordination or another, we can assess whether the dimensions of market and strategic coordination posited by varieties of capitalism theory exist and where they are present. Varieties of capitalism theory generates three hypotheses that can be tested using such an analysis:

H1: *The character of coordination constitutes a key dimension stretching across spheres of the political economy.*

If this is correct, a confirmatory factor analysis in which the latent variables are defined as the degree of coordination in each sphere of the political economy should do a good job in accounting for the observed covariance between a set of indicators representing the institutional conditions associated with different types of coordination in those spheres.

H2: *The underlying latent variables corresponding to each sphere of the economy should reflect variation along a spectrum running from market coordination to strategic coordination.*

If this is correct, the factor loadings produced by the confirmatory factor analysis should be consistent. This means that if an observable indicator of institutional support for strategic coordination loads positively (negatively) onto a given latent variable, other indicators of support for strategic coordination should also have positive (negative) factor loadings for this latent variable; whereas indicators of support for market coordination should have negative (positive) factor loadings.

H3: *It is possible to identify a distinctive set of liberal market economies that make extensive use of market coordination and another set of coordinated market economies that make extensive use of strategic coordination.*

If this is correct, when the factor loadings are used to construct scores for each nation, the nations identified by the case study literature as liberal market economies should be located toward the 'market' end of the dimension for each sphere, and those identified as coordinated market economies should be located closer to the 'strategic' end for each sphere.

The central obstacle to such an analysis is the paucity of relevant indicators available for more than a few countries. The measurement of coordination poses special difficulties. In principle, types of coordination are observable, but intense observation is required. In only one sphere has coordination been assessed in this way, namely that of wage bargaining. Accordingly, we employ two independent assessments of coordination in wage bargaining. The other variables used in the factor analysis are all indicators of institutional features of the political economy that can reasonably be said to reflect or provide support for one type of coordination or the other. We have identified variables that extend across two important spheres of the political economy, those pertinent to labour relations and corporate governance. The observations were drawn from the 1990-95 period, the latest for which comparable data is available.

The variables employed in the factor analysis are as follows:¹⁵

Shareholder Power: reflects the legal protection and likely-influence over firms of ordinary shareholders relative to managers or dominant shareholders. It is a composite measure of legal regulations covering six issues: the availability of proxy voting, deposit requirements for shares, the election of directors, the legal recourse available to minority shareholders, shareholders' rights to issues of new stock, and the calling of shareholder meetings. Regulations governing each issue are coded 0 or 1 and summed. Higher scores indicate that ordinary shareholders enjoy more rights vis-a-vis managers and dominant shareholders.¹⁶

Dispersion of Control: indicates how many firms in the economy are widely-held relative to the number with controlling shareholders. Taking the smallest ten firms with market capitalization of common equity of at least \$500 million at the end of 1995 as a sample of firms, it reports the percentage that do not have a controlling shareholder, defined as one who controls, directly or indirectly, more than 10 percent of the voting rights in the firm. Higher values indicate that larger proportions of firms in the economy are widely-held.¹⁷

Size of Stock Market: the market valuation of equities on the stock exchanges of a nation as a percentage of its gross domestic product in 1993.¹⁸

Level of Wage Coordination: the level at which unions normally coordinate wage-claims and employers coordinate wage-offers where 3 represents the national level, 2 the intermediate level, and 1 firm level. Levels of coordination for unions and employers are assessed separately and averaged. Higher values indicate higher levels of coordination in wage setting.¹⁹

Degree of Wage Coordination: reflects estimates by the OECD Secretariat of the degree to which wage bargaining is (strategically) coordinated by unions and employers along a scale on which 3 indicates coordinated and 1 indicates uncoordinated. Observations are for 1994. Higher values indicate higher levels of wage coordination.²⁰

Labour Turnover: is an indicator of the fluidity of national labour markets and reports the number of employees who had held their jobs for less than one year as a percentage of all employees surveyed in 1995.²¹

The appropriateness of these variables for the analysis should be apparent from our description of liberal and coordinated market economies. The first three variables reflect institutional variation in the sphere of corporate governance of the sort highlighted by the varieties of capitalism approach. Where the balance of influence tilts toward dominant shareholders, ownership relatively concentrated, and equity markets small, securing access to external finance and negotiating corporate control is more likely to involve firms in strategic interaction within corporate networks. When these conditions are reversed, issues of finance and corporate control are determined by more competitive markets. The next three variables reflect relevant variation in the sphere of labour relations. Two assess the level and degree of strategic coordination in

wage bargaining. Labour turnover reflects the frequency with which workers move from one firm, a measure of the fluidity of labour markets.

Figure 1 about here

Since the number of indicators available for such an analysis is limited and the likelihood of some measurement error high, we entered the analysis with low expectations. Given these constraints, the results are highly supportive of the terms the varieties of capitalism literature uses to characterize political economies. We performed the confirmatory factor analysis whose structure is presented in Figure 1.²² Table 1 reports the estimates of the linear relationship between the latent and observable variables (factor loadings) as well as a set of indicators of the ‘goodness of fit’ of the overall model. All of the factor loadings were significant by conventional standards and signed in the appropriate manner. The fit indicators suggest the model does a good job of explaining the covariance among the observed variables. As expected, the estimated correlation between the levels of coordination found in each sphere of the economy was high (-.81).²³ These results suggest that the first two hypotheses examined here should be accepted rather than rejected.

Table 1 about here.

How well do these results conform to the cross-national patterns postulated by the varieties of capitalism literature? Using the factor loadings, we construct scores for each nation for each factor, normalized to lie between 0 and 1. These scores are reported in Table 2, and Figure 2 arrays each of the OECD nations for which we have scores in a two dimensional space where movement away from the origin along the X-axis reflects higher levels of strategic (vs

market) coordination in corporate governance and movement up the Y-axis reflects higher levels of strategic coordination in labour relations. If the varieties-of-capitalism approach to understanding the institutional differences among developed political economies is correct, we should expect to see a clustering pattern: liberal and coordinated market economies should be found primarily in the southwest and northeast quadrants, respectively.

Table 2 and Figure 2 about here.

The results are broadly supportive of the hypothesis. As the regression line indicates, there is a strong and statistically significant relationship in the predicted direction between coordination in labour relations and corporate governance. Nations cluster toward the southwest and northeast quadrants of the diagram, as the theory would lead us to expect. Six nations, all normally identified by varieties of capitalism theory as liberal market economies, cluster to the southwest, on or below the regression line. The economies of northern Europe generally identified as CMEs cluster toward the northeast in this two-dimensional space.

Japan and Switzerland are the two most obvious outliers. We view their position as the result of measurement error associated with the limitations of our measure for coordination in corporate governance. The latter attaches considerable weight to the size of the stock market and both nations have large stock markets relative to their GDP. But there is also extensive cross-shareholding in these nations not picked-up by our measure of shareholder dispersion because many of the relevant holdings fall below our 10 per cent cut-off.²⁴ Nevertheless, these cross-shareholdings limit hostile takeovers and serve as vehicles for network monitoring. In short, we think an accurate assignment of these cases would put them into the northeast quadrant of the diagram. The coordination of labour relations in the Netherlands and Belgium may also be underestimated here, reflecting OECD figures that may underestimate coordination in labour

relations. Given the potential for such measurement error in indices taken entirely from external sources, however, the correspondence between the location of economies in Figure 2 and the account of such economies given by the varieties of capitalism literature is striking.

The proximity of various nations to one another in this institutional space also facilitates more fine-grained assessment of variations among the OECD economies. Correcting for measurement error, there are four distinct clusters of nations. Among the liberal market economies, the United States and the United Kingdom appear as relatively ‘pure’ cases, while four other liberal market economies stand slightly apart by virtue of systems of corporate governance in which market coordination is not as fully developed. On the other side of Figure 2, the nations most often identified as coordinated market economies lie near or above the regression line, indicating high levels of strategic coordination in both their labour and financial markets.

Six nations lie to the east in the Figure but clearly below the regression line (Sweden lies just slightly below). This is especially interesting because there has been some controversy about whether four of these nations (Spain, Portugal, France and Italy) are coordinated market economies or examples of another distinctive type of capitalism often associated with high levels of state intervention.²⁵ Figure 2 clarifies some of the issues that render these ambiguous cases. These nations all have institutional capacities for strategic coordination in labour relations and corporate governance that are higher than those of LMEs. However, their capacities for strategic coordination in labour relations tend to be lower than those in northern Europe, probably because their union movements are still divided along what used to be called ‘confessional’ lines. Although strategic coordination is clearly more important in these nations than in liberal market economies, these findings suggest there may be systematic differences in the operation of southern, as compared to northern, European economies.²⁶

3. Congruence Across Spheres of the Political Economy

Although we have focused on corporate governance and labour relations because they are the two most important spheres of the economy, regulating the supply of labour and capital, the varieties of capitalism approach also expects systematic variation, between LMEs and CMEs, across other spheres of the political economy, including those concerned with product-market competition, social protection, vocational training, and inter-firm relations. Much of the force of the varieties-of-capitalism approach as a theory of comparative capitalism rests on its claim to be able to specify systematic variations across nations that extend to many spheres of the political economy. We turn now to assessment of that claim.

In some cases, the relevant variation is in institutionalized practices; in others, it is in the formal institutions or regulatory regimes that govern endeavours in each sphere. In the varieties-of-capitalism literature, the theoretical basis for expectations of institutional congruence lies in the contention that, where institutional complementarities are available across spheres, firms and governments will often (although not always) adapt their strategies to take advantage of these complementarities.²⁷ The relationships on which we focus are as follows.

Varieties-of-capitalism analysts argue that, where *labour relations* are based on high levels of job mobility and firm-level wage-setting, *training systems* that provide general skills through formal education will be more efficient than collaborative training schemes that confer industry-specific skills, because workers who must frequently shift jobs have strong incentives to acquire the general skills that qualify them for other positions. Conversely, where labour relations are based on strong unions and coordinated wage bargaining, it will be efficient for firms to operate collaborative training schemes conferring high levels of industry-specific skills. High wages set at the industry level encourage workers to acquire industry-specific skills, and they make it more difficult for non-training firms to poach workers by offering wage premiums. The organizations that coordinate wages can also be used to coordinate training systems.²⁸

A similar set of arguments specifies the potential for institutional complementarities between the character of *corporate governance* and the character of *inter-firm relations*. Firms are said to find it easier to enter into collaborative arrangements with other firms – for the purposes of research, product development or technology transfer – where the institutions of corporate governance limit the demands on them to maximize current profitability or shareholder value, because they can then make more credible commitments to the incomplete contracts and co-specific investments that such collaboration requires. Conversely, where fluid capital markets facilitate the movement of funds from one endeavour to another, it will be more efficient for firms to access technology by acquiring other enterprises or new personnel rather than engage in long-term collaboration with other firms.²⁹

Estevez *et al.* argue that *social policies* providing generous employment and unemployment protection will be complementary to *production strategies* based on the use of specific skills because they provide workers with incentives for acquiring those skills.³⁰ Hall and Soskice argue that high levels of *product-market regulation* may be complementary to *financial systems* based on network monitoring, to wage coordination, and to inter-firm collaboration in research and development because they limit the intensity of competition in product markets that might otherwise undermine cooperation in these other spheres.³¹

The varieties of capitalism perspective also identifies potential complementarities between institutional arrangements in the broader political economy and the *strategy or structure of firms themselves*. This is the basis for an important set of claims that corporate structures and strategies are likely to vary systematically across nations. The theory suggests that, where fluid labour markets facilitate lay-offs and dispersed financial markets often demand them, it will be advantageous for firms to adopt hierarchies that vest management with extensive prerogatives over such matters. Conversely, where strong trade unions or regulatory regimes inhibit lay-offs, corporate structures that provide stakeholders with more influence over enterprise decision-

making may offer efficiencies by strengthening the credibility of the commitments a firm can make to its employees and thus the levels of cooperation it can secure from them. On such reasoning, the approach contends that firm strategy will vary systematically across political economies in tandem with the institutional support provided there for different types of coordination. Firms are said to exploit this institutional support to derive competitive advantages that cumulate into comparative institutional advantages at the national level.³²

In short, the varieties of capitalism literature contends that systematic variation across nations is present not only in labour relations and corporate governance, but also across many other spheres of the political economy, extending to relevant regulatory regimes and firm practices. To assess this contention, we have sought indicators for the types of variation in institutions or practices that varieties of capitalism theory expects to find in a wide range of spheres of the political economy. Finding indicators for the relevant institutional dimensions is a major challenge if more than a handful of cases are to be considered and we are not to code them ourselves – a technique we have resisted in order to avoid biasing the tests. However, we have found indicators for the relevant types of institutional variation across seven spheres where the varieties-of-capitalism approach suggests major complementarities are available and some institutional congruence should be found.³³ For labour relations and corporate governance, we use the same indicators employed in the preceding analysis. The others are as follows:

Social Protection refers to the level of support provided to the unemployed and to limitations on the right of firms to lay-off workers. We measure it by combining the indices of ‘unemployment protection’ and ‘employment protection’ devised by Estevez *et al.* using the factor scores produced when an exploratory factor analysis is applied to the two indices. Higher values indicate higher levels of social protection.³⁴

Product Market Regulation refers to the limits placed on competition in product markets by the regulatory restrictions that national governments impose on businesses. The measure is based on an OECD survey of many types of regulatory practices combined into a composite measure through multi-level factor analysis by Nicoletti *et al.*³⁵ Higher values indicate product market regulations more restrictive of competition.

Training Systems are assessed with a view to establishing the extent of institutional support a nation provides for the development of vocational skills in young workers beyond what they secure in formal secondary or university education. In general, this entails apprenticeship schemes or training programs dependent on the collaborative involvement of firms. The measure is based on the factor scores produced by an exploratory factor analysis on two variables: the number of pupils at the upper secondary level in vocational or technical training programs as a proportion of all students enrolled in educational programs and the mean scores on a literacy test secured by a sample of workers between the ages of 20 and 25 who left school before completing secondary education.³⁶ Higher values indicate higher levels of institutional support for this kind of vocational training.

Inter-Firm Relations refer to the institutionalized practices that link firms to other firms producing goods and services. Of particular relevance is the extent to which firms collaborate with others to secure access to new technology or markets relative to their reliance on competitive market relations for such purposes. Mergers and acquisitions are typical of the latter. Accordingly, the measure is based on the annual number of mergers and acquisitions in a nation during 1990-97 expressed as a ratio of its population.³⁷ We reverse the direction of the measure so that higher values indicate more inter-firm collaboration.

To assess the ancillary claim that systematic variation in the institutions of the political economy will be associated with distinctive types of firm structures and strategies, we have also sought measures for the latter, as follows:

Managerial Prerogative refers to the extent to which firms concentrate control over their operations in the hands of top management. On the premise that compensation will correspond to the level of responsibility they are assigned for the firm's operations, our measure is the average compensation of chief executive officers as a ratio of the compensation of average production workers in manufacturing in 1999.³⁸ Higher values indicate higher levels of managerial prerogative.

Employment Tenure is a measure of the length of time employees typically stay with the same firm, assessed here by median employer tenure in 1995.³⁹ This can be read as a reflection of the extent to which firm strategies turn on the development of close relations with a stable workforce rather than on production regimes that can be operated by more transient and potentially less-skilled labour.

Firm Strategy is a composite measure tapping many of the core practices of firms, including the use they make of multidivisional project teams, participatory work teams, alliances with other firms, close, voice-based relations with suppliers, long-term relations with investors, and cooperative labour-management relations built on employment guarantees. Each practice has been coded on a 3 point scale and combined via factor analysis by Hicks and Kenworthy.⁴⁰ Higher values indicate firm strategies that make more extensive use of these 'cooperative' practices.

Using these variables, we test the following hypothesis:

H4. *Institutionalized practices extending across the spheres of the political economy identified here, including those associated with firm strategies, vary systematically such that the practices*

associated with market coordination are present in multiple spheres of political economies classified as LMEs and practices associated with strategic coordination are present in multiple spheres of political economies classified as CMEs.

If this is correct, there should be significant correlations across spheres at the national level among the variables representing the institutional practices the varieties-of-capitalism perspective identifies as important to coordination.

Figure 3 about here.

Figure 3 summarizes the results of this test. The boxes around ‘firm strategy’ represent the four spheres in which a firm coordinates with other actors to accomplish its principal endeavours. The two boxes at the top indicate policy regimes relevant to this coordination. The lines between the boxes correspond to hypotheses about complementarities generated by the varieties-of-capitalism literature. Using cross-national comparisons of all the cases for which we have relevant measures, we have calculated correlation coefficients indicating whether the presence of institutional practices of a particular type in one sphere are associated with institutional practices in adjacent spheres that correspond to those posited by a varieties-of-capitalism perspective. That perspective predicts positive coefficients across the diagram. The results are impressive. The coefficients in Figure 3 are uniformly positive and relatively large. All are statistically significant at the .05 level. The uniformity of the results is striking. They tend to confirm the varieties-of-capitalism contention that differences based on market-oriented or strategic coordination stretch systematically across multiple spheres of the political economy. The results on firm strategy indicated in Figure 3 are also notable: they confirm that corporate strategies tend to vary systematically with the institutional support available for different types of coordination in the political economy. Table 3 provides further evidence by comparing the relationship between two

indicators for corporate strategy and national scores on the coordination indices. In each case, there is a strong and statistically significant correlation in the direction posited by the theory.

Table 3 about here.

4. The Effect of Institutional Complementarities on Economic Growth

These results indicate that the patterns of institutionalized practices the varieties-of-capitalism perspective expects to see across the developed economies are often present there. We turn now to one of the most important propositions linked to this observation, namely to the claim that there is, not only congruence among institutional practices in different spheres of the economy, but that some of these practices can be complementary to others. Institutional practices are said to be complementary when each raises the returns available from the other. We focus on one of the most fundamental sets of complementarities, namely those between institutional practices in the sphere of corporate governance and in labour relations.

Working from the formulations of Aoki, Hall and Soskice develop a theoretical rationale for why such complementarities might exist.⁴¹ They argue that institutions in the sphere of corporate governance that encourage cross-shareholding and concentrate control in the hands of management, thereby limiting hostile takeovers and providing firms with access to sources of finance that turn on reputational monitoring, enhance the efficiency of institutional practices in the sphere of labour relations that provide high levels of employment security and long job-tenures as well as forms of wage-setting that depend on strategic interaction among employers associations and trade unions.⁴² In the face of a fluctuating economy, firms that do not have to sustain current profitability are better placed to make long-term commitments to their employees about wages and jobs, and therefore to realize the gains available from deploying production

regimes based on such commitments. This combination of institutions corresponds to the institutional patterns in CMEs.

Conversely, where firms are more dependent on dispersed equity markets, face the prospect of hostile takeovers, and confront regulations that give shareholders more power relative to stakeholders, the autonomy of the firm and its managers will be more dependent on current profitability. Here, labour markets allowing for high levels of labour turnover and competitive wage-setting will be more efficient, because they enable managers to reduce staffing levels quickly or to hold down wages in response to fluctuations in current profitability. This combination of institutional practices corresponds to the case of a LME. In summary terms, the efficiencies available to firms should be higher in settings where the spheres of labour relations and corporate governance are *both* dominated by the practices characteristic of either strategic or market coordination and, according to the varieties of capitalism analysis, these efficiencies should show up in improved aggregate economic performance.⁴³

Our indicator for aggregate economic performance will be rates of economic growth per capita, widely accepted as the best measure of such performance and appropriate for testing postulates about the general efficiency of the economy. Moreover, this measure provides an exceptionally hard test for institutional analyses such as these. Because aggregate rates of growth depend on the efficiency of the entire economy, specific sets of institutions will have to make substantial contributions to efficiency to show up in aggregate rates of growth. To summarize the character of coordination in labour relations and corporate governance, we use the two indices developed here. Although time-variant measures would be preferable, the difficulties of measuring coordination and data limitations preclude them. However, we think the use of these two indices is appropriate because they capture differences across political economies widely seen as stable over time. As a check on this, we examined Kenworthy's measures for coordination in wage setting, which do vary over time.⁴⁴ On his measure, only three of our eighteen countries

evince much fluctuation on his measure over the 1971-1997 period, and we assess the specific import of those cases for our results below. Our own examination of institutional change in the 1980s and 1990s also finds considerable stability in the cross-national differences relevant to coordination. Therefore, this approach to the measurement of coordination should be adequate for the purposes at hand.

We estimate the interaction effects between these two measures of coordination and their impact, with a range of appropriate controls standard in the growth literature, on annual rates of per capita economic growth for twenty OECD nations from 1971 to 1997, taking two different econometric approaches to the panel data.⁴⁵ The two estimators we employed were pooled ordinary least squares regression with panel-corrected standard errors and the generalized least squares random effects estimator.⁴⁶ The former is traditionally employed for times series-cross section data, i.e. data sets in which the number of observations over time is large relative to the number of panels. The technique produces correct standard errors in the presence of an error term that is heteroskedastic and contemporaneously correlated across countries. The latter is traditionally employed for panel data, i.e. data sets in which the number of panels is large relative to the observations over time. This technique produces consistent coefficient estimates and standard errors in the presence of a composite error term that consists of a (mean zero) time-invariant, country-specific disturbance (representing unmeasured features of a polity that remain fixed over time) and a traditional country-year disturbance. Since the number of panels and time periods in our dataset were roughly equivalent ($N = 20$, $T = 27$), we present the results for both estimators.⁴⁷

For each econometric technique, we estimate two separate regression equations, one containing the coordination indices and their interaction effect along with a standard set of economic controls, and another containing the coordination indices and their interaction effect,

the economic controls and a set of political institutional variables. The two equations estimated were the following:

$$Y_{it} = \beta_0 + \beta_1 C_i^{LR} + \beta_2 C_i^{CG} + \beta_3 C_i^{LR} \cdot C_i^{CG} + \beta_4 \ln GDP_i + \beta_5 Int_{it} + \beta_6 \pi_{it} + \beta_7 Exp_{it} + \beta_8 D_{it} + \varepsilon_{it}$$

$$Y_{it} = \beta_0 + \beta_1 C_i^{LR} + \beta_2 C_i^{CG} + \beta_3 C_i^{LR} \cdot C_i^{CG} + \beta_4 \ln GDP_i + \beta_5 Int_{it} + \beta_6 \pi_{it} + \beta_7 Exp_{it} + \beta_8 D_{it} + \beta_9 PLU_{it} + \beta_{10} MAG_{it} + Leftcab_{it} + \varepsilon_{it}$$

where C_i^{LR} represents the character of coordination in labour relations in country i and C_i^{CG} represents the character of coordination in its sphere of corporate governance. Estimation of these models was used to test the following hypothesis derived from the varieties-of-capitalism perspective on institutional complementarities:

H5: *When there are higher levels of market (strategic) coordination in the sphere of labour relations or corporate governance, rates of economic growth increase as the level of market (strategic) coordination in the other sphere increases.*

If this is correct, the interaction term in the model, $C_i^{LR} * C_i^{CG}$, should be statistically significant and positive. A significant coefficient indicates that the impact of coordination in one sphere is dependent on the character of coordination in the other sphere, and a positive coefficient indicates that analogous types of coordination in the two spheres raise rates of growth.

The controls employed here are standard for estimating rates of economic growth: $\ln GDP_i$ is the log of gross domestic product per capita for country i at the beginning of the period controlling for ‘catch up’ effects that generate higher rates of growth in nations at lower levels of economic development. Int_{it} represents international demand conditions measured by the average rate of growth for all countries in our sample in period t except country i , weighted by the trade openness of country i . π_{it} is the country’s rate of inflation measured by the rate of increase in its consumer

price index. In the developed world, where rates of inflation are moderate, we expect them to be positively related to rates of growth. Exp_{it} is the percentage change in the income terms of trade for country i weighted by trade openness: adverse movements should lower rates of economic growth. D_{it} is the dependency ratio measured as the share of the population below the age of 15 or above the age of 65. A higher proportion of dependents is expected to lower rates of economic growth.

In recent years, political economists have evinced growing concern for the influence of electoral institutions on political rents, productivity and economic growth.⁴⁸ Accordingly, in our second regression equation, we include two variables to capture the potential influence of the electoral-institutional environment: PLU_{it} , is an indicator variable equal to 1 if a majority of representatives in lower house are elected by plurality voting and 0 otherwise; and MAG_{it} , is the average district magnitude in the lower chamber. Based on the literature about political rents, we expect PLU_{it} to be associated with higher economic growth and, since low district magnitude is a proxy for barriers to entry in the political system, higher levels of MAG_{it} may be associated with greater economic growth. In addition, we include a variable designed to capture the influence of partisan preferences: $Leftcab_{it}$ reflects left party cabinet portfolios as proportion of total cabinet portfolios. Detailed variable descriptions are provided in the appendix.

Table 4 about here.

Table 4 reports the results of the estimations. The parameter estimates are broadly stable across the four models. In all, the coefficient on the interaction term is positive, of considerable magnitude, and statistically-significant. These results tend to confirm the presence of substantial complementarities between the spheres of labour relations and corporate governance of the sort postulated by varieties-of-capitalism theory.

Using model RE•1a for the purposes of simulation, Figure 4 depicts the impact of coordination in corporate governance on economic growth for different levels of coordination in labour relations (holding control variables fixed at their mean values). Two trajectories are shown. In the first case, coordination in labour relations is held constant at its minimum value (0) and coordination in corporate governance is allowed to vary from minimum (0) to maximum (1). In this instance, the predicted growth rate declines from 2.99 per cent to .61 per cent. In the second case, coordination in labour relations is held constant at its maximum value (1) and coordination in corporate governance is allowed to vary from minimum to maximum. In this instance, the predicted growth rate increases from 1.21 per cent to 2.83 per cent.

Figure 4 about here.

The simulations show clear evidence of interaction effects between the character of coordination in the two spheres. Rates of growth are highest where competitive markets coordinate both spheres, or where strategic coordination is high in both. Where labour relations are strategically coordinated, substantial efficiencies seem to be available from strategic-coordination in the sphere of corporate governance. Where corporate governance is dominated by fluid equity markets, however, rates of growth are substantially higher when labour markets are also fluid and competitive.

Although it is beyond the scope of this paper to test for the presence of specific complementarities across other spheres of the political economy, we conduct one other assessment of these contentions at the aggregate level. The varieties-of-capitalism approach implies that aggregate economic performance should be better in nations whose institutionalized practices correspond more closely to relatively pure types of LMEs or CMEs. Long term rates of growth should be higher in countries where market or strategic coordination is more fully

developed across multiple spheres of the political economy, compared to those where the type of coordination varies across spheres or where either type of coordination is secured but in less complete form. This implication yields the following hypothesis:

H6: *Rates of economic growth should be higher in nations where levels of market coordination or levels of strategic coordination are high across spheres of the political economy but lower in nations where neither type of coordination is so well-developed or market and strategic coordination are combined.*

If this is correct, estimates for rates of growth when other relevant factors are controlled should show higher rates of growth in nations where levels of market or strategic coordination are consistently high across spheres and lower rates in other nations.

In order to test this hypothesis, we created a single coordination index using the separate indices of coordination in corporate governance and labour relations. The coordination index measuring the balance of market and strategic coordination in the political economy for country i is equal to:

$$C_i = (CG_i + LR_i) / \max(CG_i + LR_i)$$

where CG_i and LR_i refer to the score of country i on the coordination in corporate governance and coordination in labour relations indices, respectively. We then estimated the effect of coordination on annual rates of per capita economic growth for OECD nations from 1971 to 1997 using regression models of the following form:

$$Y_{it} = \beta_0 + \beta_1 C_i + \beta_2 C_i^2 + \beta_3 \ln GDP_i + \beta_4 Int_{it} + \beta_5 \pi_{it} + \beta_6 Exp_{it} + \beta_7 D_{it} + \varepsilon_{it}$$

$$Y_{it} = \beta_0 + \beta_1 C_i + \beta_2 C_i^2 + \beta_3 \ln GDP_i + \beta_4 Int_{it} + \beta_5 \pi_{it} + \beta_6 Exp_{it} + \beta_7 D_{it} + \beta_8 PLU_{it} + \beta_9 MAG_{it} + \beta_{10} Leftcab_{it} + \varepsilon_{it}$$

If the relationship between growth and coordination is U-shaped, β_1 should be negative and β_2 positive. The controls are the standard ones used previously and, once again, we estimated the model using two different types of econometric specifications.

Table 5 about here.

Table 5 reports the results of these three estimations. In all, the coefficients on coordination are significant, of the same sign, and of similar magnitude, increasing our confidence in the results. The significance and signs of the coefficients on C_i and C_i^2 indicate that the relationship between coordination and economic growth is non-linear. Using model RE•2a for the simulation, Figure 5 shows the estimated relationship between coordination and growth when the control variables are held at their means. The U-shaped relationship is apparent. Where the institutional structure of the political economy allows for either higher levels of market coordination or higher levels of strategic coordination, estimated growth rates are larger than they are when there is more variation in the types of coordination present in the political economy.

Figure 5 about here.

These results suggest that the varieties-of-capitalism approach to institutional complementarities, built on the distinction between market and strategic coordination, has real merit. When complementary institutions are present across spheres of the political economy, rates of economic growth are higher. The institutional complementarities identified by this perspective appear to offer general efficiencies.

We conducted a number of robustness checks on these results, with particular attention to cases that might not be coded entirely accurately as noted above, namely Japan and Switzerland

as noted above, and to cases where Kenworthy's index for coordination in wage-setting shows more than negligible movement over this time period, namely Denmark, Italy and New Zealand, as well as the UK which showed some movement prior to 1980.⁴⁹ We asked whether the exclusion of any of these cases, singly or together, would affect our findings. Table 6 presents the results of these re-estimations. The table depicts the coefficient on the interaction between coordination in labour relations and coordination in corporate governance as well as the coefficients on the overall coordination index and its square for each combination of excluded cases. The table clearly suggests that our results do *not* depend on the inclusion of any one of these cases. Our findings are remarkably robust to the exclusion of particular cases, and even to the simultaneous exclusion of all potentially problematic cases. Outliers and unmeasured changes in coordination over time do not appear to pose serious threats to our conclusions.

Table 6 about here.

5. Political and Economic Adjustment Paths

We conclude by turning to issues of institutional change. Although the historical record is generally supportive of the varieties of capitalism approach to comparative capitalism, a number of scholars have raised questions about the persistence of the cross-national differences identified by this analysis in the face of international pressures associated with 'globalization'.⁵⁰ The varieties-of-capitalism literature addresses such issues. Some contributors to it explore the response of firms and governments to pressures for change, outlining how existing institutions structure processes of change.⁵¹ These formulations generate a set of predictions about national adjustment paths that we now examine empirically with a view to establishing whether the categories generated by the varieties of capitalism perspective remain a relevant typology.

Economic Dynamics

There are both economic and political sides to this matter. The principal economic issue is whether institutions that appear to have been complementary in previous decades continue to be complementary as secular developments, such as the shift from manufacturing to services, technological change, and international liberalization, alter the economic challenges facing the developed democracies.⁵² These developments might alter the efficiencies available from existing combinations of institutions. If productivity growth is lower in services, for instance, the growth of that sector may undercut the efficiency gains available from systems of coordinated wage bargaining or of social protection that sustain high wage floors.⁵³ Conversely, in epochs of rapid technological advance that increase the opportunities for radical innovation, the market-oriented complementarities of liberal market economies that lend themselves to this type of innovation may offer even higher returns relative those found in coordinated market economies which are better at incremental innovation.⁵⁴ International integration could alter the value of an economy's comparative institutional advantages by improving access to production sites offering other kinds of complementarities.⁵⁵

It is beyond the scope of this article to consider the effects of each of these developments on institutional complementarities. However, a summary impression can be formed by comparing the economic impact of particular combinations of institutions in more recent years with their impact in an earlier period. For this purpose, we re-estimate the models for the economic impact of coordination in labour relations and corporate governance, allowing the coefficient on the interaction of these variables to vary across two different time periods, 1971-84 and 1985-97. These estimations are used to test the following hypothesis:

H7: *Secular economic developments over the past two decades have not altered the efficiency of the institutional complementarities between labour relations and corporate governance posited by a varieties-of-capitalism perspective.*

If this hypothesis is correct, the coefficient on the interaction term between coordination in labour relations and corporate governance, $C_i^{LR} * C_i^{CG}$, should be positive, statistically-significant, and of comparable magnitude across both periods. An F -test to evaluate the presence of structural change should fail to reject the null hypothesis of no difference across the two periods.

The results of the estimations are presented in Table 7. For both time periods, the coefficients on the interaction of coordination in corporate governance and labour relations are positive and statistically significant. Moreover, the difference in the magnitude of the coefficients across the time periods is miniscule, suggesting that the impact of institutional complementarities in these two spheres of the economy has not appreciably diminished with time. For both regressions, we performed an F -test, which indicates that we should not reject the null hypothesis of no difference across the two periods. This supports the hypothesis that secular economic developments in the 1980s and 1990s did not alter the basic complementarities identified by the varieties-of-capitalism perspective.

Table 7 about here.

Political Dynamics

The varieties-of-capitalism literature also advances a particular view of the political dynamics associated with globalization. This view is built on the contention that the market-oriented institutions of liberal market economies encourage firms, holders of capital, and workers to invest in switchable assets, whereas institutional support for strategic interaction in coordinated market

economies encourages higher levels of investment in specific assets.⁵⁶ Fluid markets that facilitate the transfer of resources among uses enhance the returns to switchable assets in LMEs. In CMEs, better institutional support for the formation of credible commitments reduces the risks of investing in co-specific assets whose value depends on the cooperation of other actors.

These patterns of investment are significant because each generates a different politics. In the face of an exogenous shock threatening returns to existing activities, holders of mobile assets will be tempted to ‘exit’ those activities to seek higher returns elsewhere, while holders of specific assets face higher incentives to exercise ‘voice’ in defence of existing activities.⁵⁷ The argument is analogous to the distinction drawn between a Heckscher-Ohlin world, where factors are mobile and shifts in relative prices (of the sort associated with increasing economic openness) generate conflict between the holders of basic factors, such as capital and labour, and a Ricardo-Viner world of sector-specific factors where shifts in relative prices inspire inter-sectoral conflicts that unite employers and workers in defence of sectoral interests.⁵⁸

From this perspective, the varieties-of-capitalism literature argues that the political response to contemporary economic challenges will vary across liberal and coordinated market economies. In LMEs, the response will be market-oriented. When returns to existing activities are threatened, holders of mobile assets, such as workers with general skills or owners of capital on fluid equity markets, will move their assets to new activities. Many will be interested, therefore, in rendering markets even more fluid and governments may be responsive to them. Moreover, where nations respond to shocks by relying on markets to adjust prices and wages, substantial shifts in the distribution of income are likely to occur, reflecting the advantages of those with market-power.

In coordinated market economies, by contrast, the varieties-of-capitalism perspective expects economic challenges to inspire a political response mediated by higher levels of asset specificity. When returns to existing activities are threatened, holders of specific assets, such as

workers with industry-specific skills and owners of enterprises deeply-invested in co-specific assets, will find it difficult to shift to new activities. As a result, they will be less inclined to favour deregulatory initiatives that increase market competition and more inclined to demand institutional support for existing activities. The result is likely to be a much slower process of liberalization and a politics that unites workers and employers in ‘cross-class’ coalitions of sectoral defence.⁵⁹

These postulates about political dynamics suggest that economic shocks will produce different institutional outcomes in liberal and coordinated market economies. Although all capitalist economies use markets to adjust and international integration automatically renders some markets more competitive, this analysis anticipates more rapid deregulation in liberal market economies, where there should be more political support for it, compared to coordinated market economies, where cross-class coalitions support existing regulatory regimes. The perspective anticipates change in all countries, including some liberalization in CMEs, but institutional adjustment paths that diverge across different types of political economies.⁶⁰

In order to assess whether that account accurately describes the response to recent challenges, we examine a number of indicators beginning with levels of inequality. If LMEs respond to economic challenges by relying more heavily on competitive markets to reset wages and prices, we should see more rapid increases in income inequality there in response to the recent experiences of globalization. Figure 6 show that this has indeed been the pattern.⁶¹

Figure 6 about here.

To what extent have the institutional differences that underpin different modes of coordination narrowed in the face of globalization? To form an assessment, we assemble indicators for the character of institutional practices in six spheres relevant to the varieties-of-

capitalism arguments. The observations are drawn from the 1980s and the 1990s, including the early 2000s where data was available, and they are reported in Table 8. We distinguish among liberal market economies, coordinated market economies, and a third group of Southern European nations termed here ‘mixed market economies’ because they are not definitively classified into the other two categories by the varieties-of-capitalism literature and cluster distinctively in Figure 2.⁶²

Table 8 about here.

The figures presented in Table 8 display substantial differences between CMEs and LMEs during the 1980s of the sort associated with different types of coordination. Of most interest, however, are the changes taking place from 1980 to the early 2000s. Did these differences between LMEs and CMEs narrow in ways that reflect convergence on a single economic model? Table 8 shows that the direction of institutional reform is often similar across the two types of political economies. But, when variation in the pace and extent of movement is considered, substantial differences in the institutional practices of CMEs and LMEs remain. Although the locus of wage bargaining has moved downward in most of these economies, for instance, the proportion of workers covered by a collective agreement declined much rapidly in liberal than in coordinated market economies. In the realm of social protection, social spending has crept upward and employment protection has declined, but differences between the two types of economies remain pronounced. While LMEs sharpened market mechanisms, many CMEs cushioned their citizens against the effects of market adjustment with increases in benefit entitlements.⁶³ In the labour market, increases in part-time employment indicate a general movement toward labour market flexibility, but LMEs increase income inequality and CMEs reduce hours of work faster than their counterparts.

Especially intriguing are indicators for the institutional practices associated with firm strategy and finance. Here, much has been made of changes in CMEs that seem to reflect convergence on the practices of LMEs. However, these figures tell a more nuanced story. In CMEs, the ratio of the compensation of chief executive officers to that of manufacturing workers and the size of stock markets increased, but the analogous increases in LMEs were also substantial, leaving large gaps in institutional practices between the two types of political economies, which is also apparent in the debt-to-equity ratios of non-financial enterprises. The figures for earnings and employment tell a classic story of different adjustment paths. Strategically coordinated wage bargaining pushed real earnings up in CMEs at rates that outpaced those in LMEs, but effective forms of coordination in the workplace and high levels of investment kept the increase in unit labour costs in CMEs roughly commensurate with that of LMEs.

On balance, we read these figures as suggesting that institutional practices did not converge dramatically in the decades after 1980. Modest efforts were made to improve the flexibility of coordinated market economies, including some liberalization of labour and capital markets, but the pace of movement was slow enough to leave significant differences in institutional practices across the two types of political economies. The absence of more convergence in the face of intense pressures during the 1980s and 1990s suggests that the distinctions drawn by the varieties-of-capitalism literature may be relevant for years to come.

Conclusion

We entered this project uncertain about whether we could find indicators for the relevant variables and what the tests of the hypotheses would reveal. We leave it impressed with the

uniformity of the results. The weight of the evidence suggests that the varieties-of-capitalism literature captures important differences among political economies. The concepts of market-oriented and strategic coordination do seem to reflect an underlying dimension distinguishing practices across countries in the spheres of labour relations and corporate governance. The contention that institutional complementarities operate across these two spheres of the political economy is also borne out by the evidence. Persistent cross-national differences in institutional practices in the face of intense pressures for convergence, suggests that, despite some liberalization in coordinated market economies, the distinctions central to the varieties-of-capitalism perspective are likely to be of continuing value.

Our findings about complementarities have especially important implications for reform proposals now being considered in the developed world. The deregulation of labour markets is a popular cause. However, our evidence suggests that labour-market deregulation is likely to produce large economic gains only in nations where financial markets are correspondingly fluid (see Figure 4). Otherwise, the gains in growth may be relatively small. Many nations have come under pressure from international agencies or global enterprises to increase competition in markets for corporate governance. However, our estimates suggest that such steps may have positive effects only where labour markets are also highly fluid.

The broader lesson is that those seeking to understand the effects of institutional change should pay careful attention to the potential for institutional complementarities across spheres of the political economy. Most proposals to reform labour or capital markets are based on estimates of the effects of such reforms that consider data only for the sphere being reformed. If the distribution of institutions across national cases were random, estimates generated from cross-national data of this sort might produce accurate results. But our evidence indicates that this distribution is far from random: nations with particular types of institutions in one sphere tend to have particular types of institutions in other spheres. As a result, models that do not take

interaction effects across institutional spheres into account may attribute to one set of institutions effects that are actually generated by interaction among several sets of institutions.

This is a research agenda rather than a counsel of despair that finds complementarities everywhere. Although there are undoubtedly other ones, the varieties-of-capitalism literature presents propositions about particular complementarities that can be examined more closely. The range of institutional indicators available for doing so is growing, as is the evidence that such analyses can be fruitful.⁶⁴ In broad terms, this analysis lends weight to the theoretical perspectives advanced in the varieties-of-capitalism literature. It suggests that the concepts of market-oriented and strategic coordination can illuminate the operation of many developed political economies and contribute important insights to understanding their politics and economic performance.

Note: The table compares average figures for 1980-89 with average figures for 1990-2002 or latest date available. For variable descriptions and sources, see Appendix 2. LMEs include: USA, UK, Canada, Australia, NZ, Ireland. CMEs include: Germany, Japan, Austria, Sweden, Norway, Denmark, Finland,

Netherlands, Belgium, Switzerland. MMEs include: Portugal, Spain, France, Italy, Greece, but sample sizes vary with data availability.

Figure 1: Path diagram of the two-factor model for the six observed variables

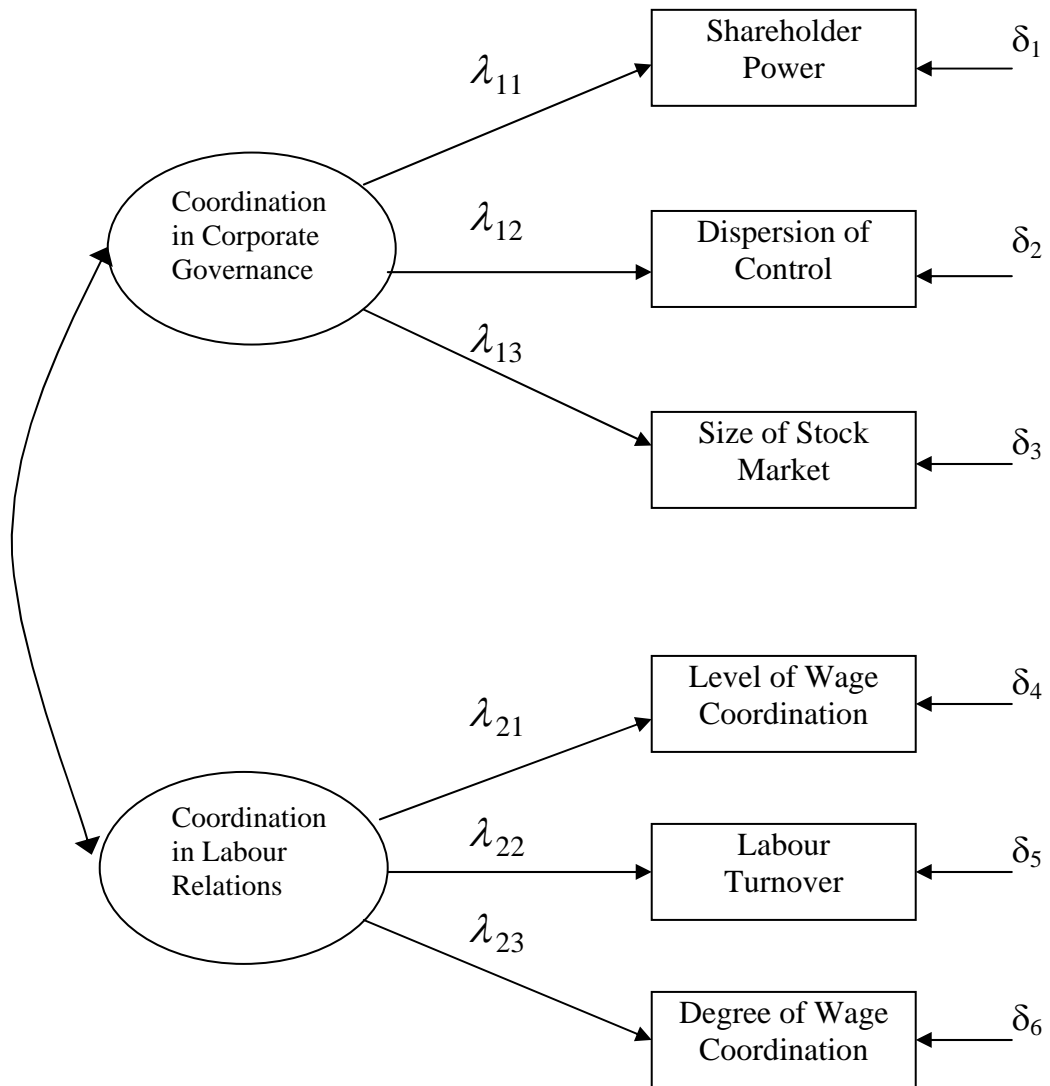

Figure 2: The balance between market and strategic coordination in labour relations and corporate governance in OECD countries

Note: On each axis, movement away from the origin indicates higher levels of strategic coordination in the relevant sphere of the political economy and movement toward the origin indicates higher levels of market coordination.

Figure 3: Potential complementarities across sub-spheres of the political economy

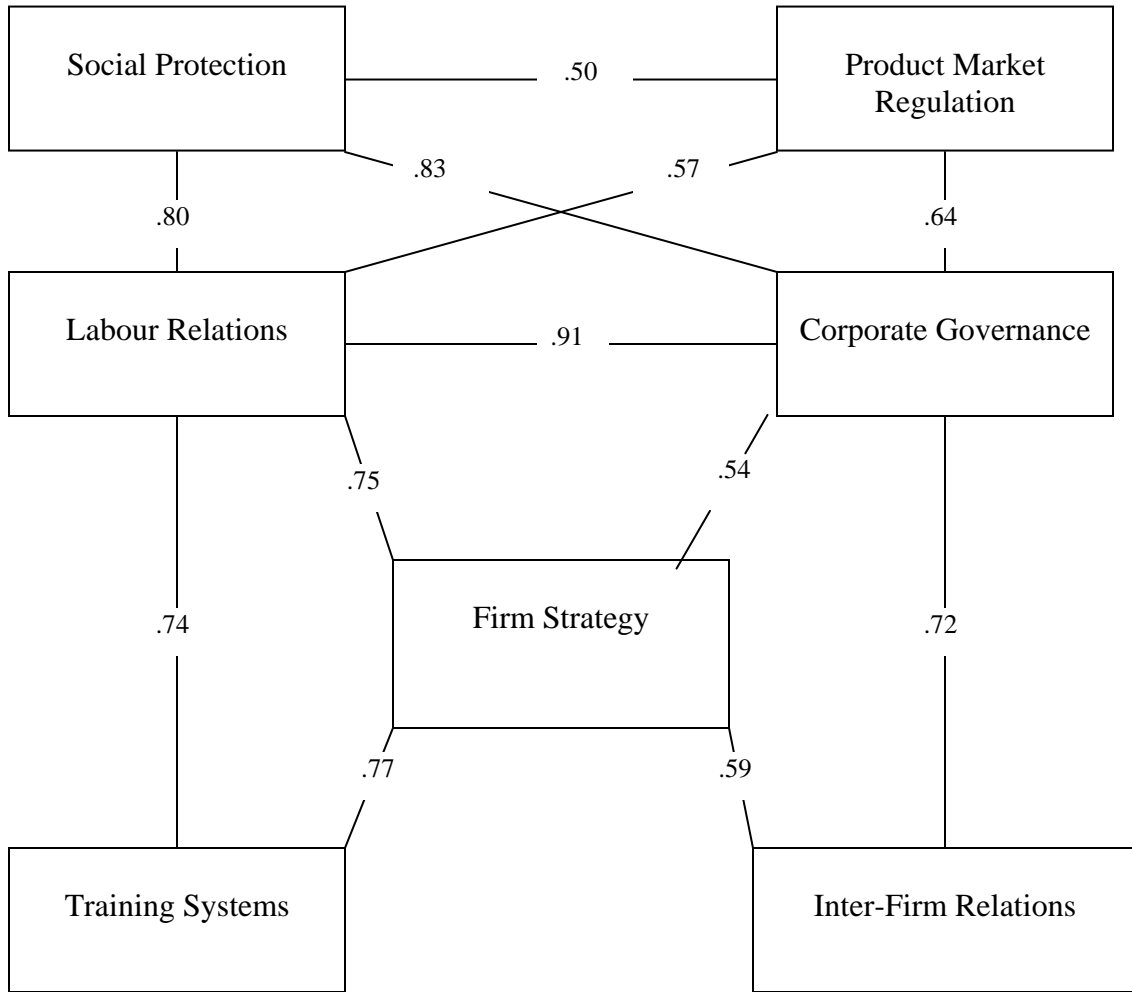

Figure 4: The effect on rates of economic growth of the interaction between types of coordination in labour relations and corporate governance

Note: Movement from the origin along the X-axis indicates that coordination in corporate governance becomes more strategic. Predicted values denoted by solid dark lines, 90% confidence intervals denoted by dashed lines; simulation based on model RE•1a

Figure 5: The estimated relationship between coordination and rates of economic growth

Note: Predicted values are denoted by solid dark lines, 90% confidence intervals denoted by dashed lines; simulation based on model RE•2a

Figure 6: Changes in inequality in disposable income in liberal and coordinated market economies, 1980-1995

Source: Luxembourg Income Study.

Appendix 1: Variable Descriptions for the Growth Regressions

<u>variable</u>	<u>definition</u>	<u>source</u>
Y_{it}	Growth rate of real GDP per capita (constant prices: chain series)	Penn World Table 6.1
$\ln GDP_i$	Log GDP per capita in 1971 calculated using real GDP per capita (constant prices: chain series)	Penn World Table 6.1
Int_{it}	Average rate of growth for the entire sample in each year weighted by a country's trade openness	openness: OECD Statistical Compendium 2006, vol.1
π_{it}	Rate of growth of inflation (as measured by the CPI)	World Bank, World Development Indicators
Exp_{it}	Percentage change in exports as a capacity to import (constant LCU) weighted by trade openness. Exports as a capacity to import equals the current price value of exports of goods and services deflated by the import price index.	World Bank, World Development Indicators
D_{it}	Percentage change in the dependency ratio (number of individuals under 15 and older than 65 as a percentage of working age population)	World Bank, World Development Indicators
PLU_{it}	1 if majority of representatives in lower house are elected by plurality voting, 0 otherwise	Database of Political Institutions, World Bank Institute, http://www.worldbank.org/wbi
MAG_{it}	Average district magnitude in the lower chamber	Database of Political Institutions
$Leftcab_{it}$	Left party cabinet portfolios as proportion of total cabinet portfolios	Duane Swank's Comparative Parties Data Set (http://www.marquette.edu/polisci/Swank.htm)

Appendix 2: Variable Descriptions for Table 8

Variable	Description	Source
Trade Union Density	Union membership as percent of labour force: 1980-89 vs 1990-2002.	Comparative Welfare States Data Set 2004, OECD <i>Employment Outlook</i> 1997, European Industrial Relations Observatory On-line
Bargaining Coverage	Percent of labour force covered by collective bargaining: 1980, 1985 vs 1990, 1994, 2000, 2001, 2002	OECD <i>Employment Outlook</i> 1994, 1997, European Industrial Relations Observatory On-line
Bargaining Level	Degree of centralization in wage bargaining: 1980-89 vs 1990-2000	Comparative Welfare States Data Set 2004, OECD <i>Employment Outlook</i> 1997, European Industrial Relations Observatory On-line
Employment Protection	Strictness of legislation for regular and temporary contracts: late 1980s v late 1990s	OECD <i>Employment Outlook</i> 1997
Benefit Entitlements	Gross replacement rate for unemployment benefit averaged over earning levels and family situations: 1981,83,85,87,89 v 1991, 93,95,97,99	OECD Benefits and Wages Indicators 2002.
Social Spending/GDP	Public social expenditure as a percent of GDP: 1980 v 2003	OECD <i>Factbook</i> 2007
Part-Time Employment	Percent of labour force employed less than 30 hours per week in their main job: 1980-89 v 1990-2002	OECD <i>Labour Force Statistics</i> 2003.
Average Hours Worked	Hours per year worked per person in employment: 1980 v 2005	OECD <i>Factbook</i> 2007.
Income Inequality	Gini Coefficient for disposable income: year closest to 1980 v most recent available year	Luxembourg Income Data Study Key Figures.
Average Job Tenure	Average number of years employed with same firm: 1980, 85, 89 v 1990, 91, 95	OECD, <i>Employment Outlook</i> 1993, 1997.
CEO Compensation	Ratio of total CEO compensation and benefits to that of manufacturing operatives: 1984 v 1996	Abowd, John M. And David S. Kaplan, 'Executive Compensation, Six Questions that Need Answering,' National Bureau of Economic Research Working Paper No. 7124. May 1999.
Stock Market Capitalization	Ratio of stock market capitalization to GDP: 1980-89 v 1990-2001	World Bank Online Database.
Debt/Equity Ratio	Ratio of debt to equity for non-financial enterprises: 1980/85 v 1992/3	OECD <i>Economies at a Glance: Structural Indicators</i> 1996.

Real Earnings	Year to year percent change in real hourly earnings in manufacturing: 1980-89 v 1990-2000	OECD <i>Historical Statistics</i> 2001.
Unit Labour Costs	Wages, salaries employer contributions per unit of output: 1980-89 v 1990-2000	OECD STAN Indicators database.
Total Employment	Total employment as percent of population aged 15 to 64: 1980-89 v 1990-2000.	OECD <i>Historical Statistics</i> 2001.

¹⁰ This approach originates in the early work of David Soskice and the account given of it here draws extensively on joint work with him. See David Soskice, 'Reinterpreting Corporatism and Explaining Unemployment, Coordinated and Non-coordinated Market Economies' in R. Brunetta and C. Dell'Aringa, eds., *Labour Relations and Economic Performance* (London: Macmillan, 1990), 170-214;

David Soskice, 'The Institutional Infrastructure for International Competitiveness, A Comparative Analysis of the UK and Germany' in A.B. Atkinson and R. Brunetta, eds, *The Economics of the New Europe* (London: Macmillan, 1991), 45-66.

¹¹ This list of the institutional correlates of effective strategic coordination is a familiar one that draws on the conventional literature plus the presence of a capacity for deliberation whose importance is outlined in Hall and Soskice, 'Introduction'. See Elinor Ostrom, *Governing the Commons: The Evolution of Institutions for Collective Action* (New York: Cambridge University Press, 1990).

¹² The approach concentrates on cross-national variation because it examines spheres where national regulations and nationally-specific institutions are especially important, but it acknowledges there can be additional variation across specific regions or sectors. See John L. Campbell, Rogers Hollingsworth and Leon Lindberg, *Governance of the American Economy* (New York: Cambridge University Press, 1991); and Gary Herrigel, *Industrial Constructions: The Sources of German Industrial Power* (New York: Cambridge University Press, 1996).

¹³ Of course, the distinction between institutions and coordination is a narrow one, especially if coordination is construed as rule-patterned behaviour. Here, institutions are defined as rules and practices, more or less formal, that actors take into account when making decisions about what actions to undertake. These include the institutions generated by the organizational setting. See Hall and Soskice, 'Introduction', p. 9; Randall Calvert, 'The Rational Choice Theory of Social Institutions: Cooperation, Coordination and Communication' in J. Banks and E. Hanushek, eds, *Modern Political Economy* (New York: Cambridge University Press, 1995), pp. 216-67.

²⁰ Organization for Economic Cooperation and Development, *Employment Outlook* (June 1997), 71.

²¹ *Ibid*, p. 138. The value for New Zealand on this variable is estimated using a multiple imputation technique.

²² The path diagram reflects the following assumptions. First, we assume that the covariance among our observed variables is a function of the presence of two latent (unobservable) variables: the balance between market-based and strategic coordination in the sphere of corporate governance and in the sphere of labour relations. Second, we assume that each latent variable is linearly related to the corresponding observable variables within its particular sphere of the economy. Coordination in one sphere of the economy does not exert a *direct* linear effect on the level of the observable variables found in the other sphere of the economy. Third, we assume that our two latent variables are correlated: given the presence of institutional complementarities, we would expect countries characterized by high levels of one type of coordination in one sphere to have high levels of coordination in the other sphere. Thus, the empirical model reflects our theoretical belief that variation in the observable variables found in one sphere of the economy is related to the level of coordination found in the other sphere of the economy only by way of the correlation between

the levels of coordination in the two spheres, which in turn is a function of the presence of institutional complementarities. Our final assumption is that measurement error across our observable variables is uncorrelated.

²³ The estimated correlation is negative because the latent factor driving the covariance between the corporate governance indicators is the degree of strategic coordination whereas the latent factor driving the covariance between the labour relations indicators is the degree of market coordination (i.e. strategic coordination in reverse).

²⁴ Paul Windolf, *Corporate Networks in Europe and the United States* (New York: Oxford University Press, 2002); Mark J. Roe, 'Political Preconditions to Separating Ownership from Corporate Control', *Stanford Law Review* 53 (2000), 539-605.

²⁵ Schmidt, *The Futures of European Capitalism*; Amable, *The Diversity of Modern Capitalism*; Hall and Soskice, *Varieties of Capitalism*, Martin Rhodes 'Globalisation, Labour Markets and Welfare States, A Future of 'Competitive Corporatism'?' in Martin Rhodes and Yves Meny, eds, *The Future of European Welfare* (London: Macmillan, 1997), 178-203.

²⁶ The varieties-of-capitalism literature acknowledges that such differences may exist. Those between the 'industry-coordinated' economies of northern Europe and 'group-coordinated' economies of Asia have been elaborated most fully. See David Soskice, 'National Patterns in Company Innovation Strategies: A Comparative Institutional Approach' WZB, 1996.

²⁷ Note that our concern here is simply to assess whether the institutional patterns that the varieties-of-capitalism approach expects to find across nations actually occur and not to assess explanations for why these institutional patterns arise. Many causal processes may underlie such patterns and our analysis is not meant to imply that they arise for any specific set of functional reasons.

⁴⁰ This measure uses the average 1960-89 scores for a factor that Hicks and Kenworthy label 'firm-level cooperation' which includes some further variables assigned low weights that we do not enumerate here; Alexander Hicks and Lane Kenworthy, 'Cooperation and Political Economic Performance in Affluent Democratic Capitalism', *American Journal of Sociology* 103 (1998), 649.

⁴¹ Masahiko Aoki, 'Toward an Economic Model of the Japanese Firm', *Journal of Economic Literature* 28 (1990), 1-27; Masahiko Aoki, 'The Japanese Firm as a System of Attributes, A Survey and Research Agenda'; Hall and Soskice, 'Introduction'.

⁴² When we say that one institutional practice enhances the efficiency of another, this means that its presence increases the returns available from using the other institutional practice.

⁴³ The terms ‘market’ and ‘strategic’ coordination refer to broad patterns of firm behaviour that tend to be altered only by large-scale institutional changes: no one has suggested that any measure to introduce some competition into one of these spheres necessarily impairs strategic coordination in the other. Similarly, although these institutions also have distributive effects that increase the returns to particular actors, following the varieties of capitalism literature, we focus here on returns to the economy as a whole of the sort reflected in aggregate economic performance.

⁴⁴ Lane Kenworthy, Wage Setting Coordination Scores. 2001. Available at, <http://www.u.arizona.edu/~lkenwor/WageCoorScores.pdf>.

⁴⁵ The countries included in the estimations consist of all those for which it was possible to calculate the coordination indices. See Table 2 for the complete list.

⁴⁶ Nathaniel Beck and Jonathan Katz. ‘What do Do (And Not to Do) with Time-Series Cross-Section Data’, *American Political Science Review* 89 (1995), 634-48.

⁴⁷ One of the more common approaches to statistical analysis with panel data, namely, fixed effects regression, was unavailable to us as a result of the time-invariant nature of our coordination indices.

⁴⁸ T. Persson. and G. Tabellini, *The Economic Effects of Constitutions*. (Cambridge, Ma: MIT Press, 2003).

⁴⁹ As a summary measure of variation over time, we calculated the percentage of years in which a country’s wage coordination score was less than or equal to 1 point away from its modal score during the 1971-1997 period. For all countries except for Denmark, Italy, and New Zealand, this percentage was greater than 70 per cent.

⁶⁰ Hall, 'The Evolution of Varieties of Capitalism in Europe'.

⁶¹ For the empirical analysis in this section of the paper, we adopt the classification of political economies that Hall and Soskice use, terming those that they do not classify definitively as liberal or coordinated

market economies, mixed market economies. Portugal, Spain, France and Italy are in the latter category. See Hall and Soskice, 'Introduction'.

⁶² As labeled here, mixed market economies include those that fall clearly below the regression line on the right hand side of Figure 2, i.e. Spain, Portugal, Italy and France.

⁶³ However, some of these entitlements are being gradually reduced again. See Elmar Rieger and Stephan Leibfried, *Limits to Globalization, Welfare States and the World Economy* (Cambridge: Polity Press, 2003).
