Fritz Engineering Laboratory Report No. 400.35

1. INTRODUCTION

The material contained in this document was assembled to assist
the beginning users of microcomputers with MS-DOS operating sys-
tem (disk operating system by Microsoft), WATFOR-77 FORTRAN com-
piler and WEDIT editor by WATCOM. The material presented herein
was extracted from voluminous publications by Microsoft and WAT-
COM products. For advanced applications of MS-DOS and WATFOR-77,
it is suggested that the readers refer to these parent publica-
tions.

This document is subject to periodic modifications, as the ver-
sions of MS-DOS and WATFOR-77 used at Lehigh University are up-
dated. The descriptions contained in the document are based on
the diskettes employed by ENG-1: Engineering Computations course
in the College of Engineering and Applied Science of the Univer-
sity. If there are any doubts regarding the compatibility of the
document versus the ENG-1 diskettes, it is strongly recommended
that the prospective user check with the User Services of the
Lehigh University Computing Center (LUCC) or the course leader of
ENG-1.

This document has evolved from various handouts prepared by LUCC
staff and ENG-1 course leader. These handouts were prepared
primarily by Drs. G. Oberlander and S. K. Tarby.

2. MS-DOS COMMANDS FOR WATFOR-77 USERS

2.1 Starting Your MS-DOS Computer

1. You will need a "boot diskette" to start a floppy disk-based computer (a later step will explain how this diskette is created). For your convenience, the ENG-1 WATFOR-77 diskette No.1 is a boot diskette. Place WATFOR-77 diskette No.1 in the uppermost drive (if the floppy drives are placed vertically) or in the leftmost drive (if the drives are arranged horizontally). This is the "A" drive, from which the computer is usually started. The other floppy drive is called the "B" drive. Place WATFOR-77 diskette No. 2 in the "B" drive. If there is a hard disk present, it is designated the "C" drive, whether or not there is a "B" drive present. The floppy diskette is inserted into the drive with the label side uppermost, and with the label on the trailing edge of the diskette (the side away from the computer). Be sure to close the "door" on each floppy disk drive. Turn on the power to the computer and power the monitor.

> *In order for the WATFOR-77 software to work as intended, it is ABSOLUTELY ESSENTIAL that the computer be booted with WATFOR-77 disk 1 in drive "A" and WATFOR-77 disk 2 in drive "B".*

2. After a few moments, prompts for date and time will appear. You can bypass the requested date and time input by hitting the ENTER key at each prompt. However, it is strongly recommended that you enter both date and time, since a file's directory entry includes date and time fields which are useful in determining when a file was last modified or created.

3. After dealing with the date and time input, a message will appear instructing you to type "WATFOR77" and press the RETURN key, to start the WATFOR-77 compiler and editor. Below this message you will see the MS-DOS prompt "B:\>". This prompt tells you that "B" drive is the default drive, and the ">" symbol tells you that MS-DOS is loaded and running.

4. To change the default drive, type the letter of the desired drive, immediately followed by a colon, e.g. "A:". Hit the "RETURN" key. All MS-DOS commands are case insensitive so you may use upper or lower case at will. You may even mix the two. Note the new prompt indicating the new default drive.

When using WATFOR-77, you will want the "B" drive to be the default disk drive, as a general rule. The reason for this is that WATFOR-77 disk 2 contains approximately 260,000 characters of free storage space (which is a fair amount of space), whereas WATFOR-77 disk 1 contains about 24,000 characters of free space (which is relatively little space). FORTRAN programs which you write during the semester can be stored on disk 2. Change the default disk drive back to "B" before continuing.

2.2 Some Keyboard Pointers

1. Viewing the keyboard from left to right, three sections can be distinguished. The first section consists of two columns of function keys. The second section consists of all alphabetic and punctuation characters, as well as the RETURN, ESCape, CTRL, SHIFT, and ALT keys. The last section comprises (among others) the numeric keypad, the INSert, DELete, NUMber LOCK, PRT SC (print screen) and SCROLL LOCK/BREAK keys.

2. The 10 function keys are all programmable and WEDIT, the WATFOR-77 program editor, makes use of all of them. When MS-DOS is running, only the first five function keys have assigned functions. Of these five, the F1 and F3 keys are most useful. Both keys allow you to repeat the previous MS-DOS command. Each time you hit the F1 key, a single character from the previous command is entered at the current prompt. Hence, you can repeat a command up to a certain point, correct an error or change a parameter, and then finish the command by using either F1 or F3 keys. Pressing the F3 key causes the entire previous command to be re-entered.

3. The ESCape, CTRL, and ALT keys can take on special functions in a given applications program. In MS-DOS, the key sequence CTRL ALT DEL (all pressed simultaneously) will reboot the computer, and when a WATFOR-77 program is running, the sequence CTRL BREAK (pressed simultaneously) will terminate that program.

4. The keys of the numeric keypad are dual function keys. If the SHIFT or NUMber LOCK keys are not active, then the function labeled on the lower part of each key can be executed, e.g. END, HOME, PGUP (page up) and PGDN (page down) have no functions when MS-DOS is running, though they are all employed by WEDIT.

5. The backspace key will rub out the character to the left of the cursor in MS-DOS and in most applications programs. It should not be confused with the left arrow key on the numeric keypad which, in most application programs, moves the cursor left without any rub out function.

2.3 Preparing Floppy Diskettes for Use
1. New floppy diskettes must first be formatted before they can be used. You must decide when formatting a diskette whether you also want to make it a boot diskette. Diskettes used only for data storage should probably be formatted without a boot option, which will save you around 60,000 characters of storage space (this being the space required by the system boot programs). In order to format a diskette, you need WATFOR-77 Diskette No.1. The latter has, in addition to its boot capability, a utility program which formats diskettes.

2. To format an ordinary non-bootable diskette, place WATFOR-77 diskette No.1 in drive "A" and a blank diskette to be formatted in drive "B". Make sure that the default drive is "A." Type the command "FORMAT B:". You will then be prompted with a few simple instructions. Then you will be asked if you want to give the diskette a volume label. This is optional; the volume label serves as an internal diskette label and appears whenever a directory command is given.

3. To format a boot diskette, follow the instructions immediately above, using the command "FORMAT B:/S". Do not include spaces from the "B" onward. REMEMBER: When a diskette is formatted, all the contents will be LOST!

4. After you are finished formatting floppy diskettes, be sure to change the default disk drive back to "B", and be sure to insert WATFOR-77 diskette No. 2 back into drive "B" before using WATFOR-77.

4

2.4 The Directory

The basic command to display a listing of files from a diskette is "DIR" (for the default drive) or "DIR d:" for a non-default drive, where "d" is the desired drive. For example, "DIR" gets a directory of the default drive and "DIR A:" will get a directory of drive "A:". Note that the latter command will not change the default drive. Often, the file listing will scroll off the screen. You can compensate for this in several ways: if you hold down the "CTRL" key and press the "S" key, the display will stop scrolling - pressing any key will cause the scrolling to resume; type "DIR/P" to cause the listing to pause after each screen of new information; or type "DIR/W" to display the directory in a wide format which leaves off some information so that many more entries can be displayed.

2.5 Filenames

1. Filenames in MS-DOS consist of a primary file name up to 8 characters followed by an optional extension consisting of period and up to 3 characters. Virtually any character accessible from the keyboard is allowed in file names, except non-printing or special function characters (mathematical symbols, the asterisk, slash, backslash, colon, etc.). Note that embedded blanks are not allowed.

2. In addition to the primary file name and extension, a file may also be designated by the drive and directory in which it resides. This compound file designator is called the file specification. For example, "B:\WATFOR\MATRIX.FOR" designates the file "MATRIX.FOR" on drive "B", in subdirectory "WATFOR".

2.6 Copying Files

The basic format of the copy command is: "COPY d1:filename d2:filename", where "d1" is the source drive and "d2" is the target drive. For example, "COPY A:STUFF.FOR B:STUFF.FOR". This is the long form of the copy command, and it can be shortened in several ways. First, if the target filename is to remain the same as the source filename, it need not be repeated. The above example would then become "COPY A:STUFF.FOR B:". Note where there is a blank between characters and where there is no blank.

If the default drive was drive "A", then the example could be further shortened to "COPY STUFF.FOR B:". It is recommended, however, to fully specify source and target file designators until you become experienced with this command. Otherwise, there is a potential to accidentally reverse the intended direction of the copying, i.e., possibly copying an out-of-date file on top of a new file.

2.7 Wildcard Characters

1. MS-DOS employs two wildcard characters, the "*" and the "?". The latter symbol represents any single character. So, for example, the command "DIR ?BC" will list any files on the default drive which have file names of three characters, the first character being anything and the remaining characters being "BC". "?" actually represents any single character or no character! DIR ?BC would thus list BC if it existed. ???? represents 0-4 characters, for example.

The "*" stands for any number of characters up to eight. For example, "COPY ABC.* C:" will copy all files on the default drive which have a primary file name "ABC" and any characters in their extension. A common use of the "*" wildcard is the sequence "*.*", e.g., "COPY *.* A:", which will copy every file in the current directory of the default drive into the current directory of drive "A". "COPY *.FOR A:" IS AN EASY WAY TO BACK UP FORTRAN PROGRAMS. *ALWAYS BACK UP YOUR WORK.*

2.8 Handling Subdirectories

1. MS-DOS allows the use of subdirectories on both hard disk and floppy diskette. The root directory is symbolized by the backslash "\". This directory is created when a diskette is formatted.

2. If we give the command "MD directoryname", a subdirectory will be created one level below the current directory. The directory name may be up to 8 characters long, and may have an optional extension up to three characters long (the extension is usually omitted). To change the current directory to this new subdirec-

tory, type "CD directoryname". If we give another "MD" command in this directory, we will create a new subdirectory two levels below the root directory.

3. The command "CD" by itself will show the current directory. If the current directory is the root directory, then a backslash will be the response to this command. Note that the current directory is automatically displayed as part of the MS-DOS prompt.

4. To move up one level in the subdirectory structure, type "CD..". The two dots stand for the parent directory of the current subdirectory.

5. To go directly to the root directory, type "CD\" (remember the backslash is the symbol for the root directory).

6. To change to a subdirectory more than 1 level below the current directory, you must indicate each intervening subdirectory, each separated by a backslash, e.g., "CD\subdirectory1\subdirectory2".

7. To remove a subdirectory, all files in that subdirectory must be deleted. Then, the current directory must be at least one level above the subdirectory in question. Finally, the command "RD subdirectoryname" can be given.

8. When referencing a file not in the current directory, the subdirectory which contains it must be explicitly specified, e.g., "COPY C:\subdir1\subdir2\filename A:". The COPY, DELete, REName, and TYPE commands (to be treated in the next section) all come under this requirement.

2.9 Other Important Commands
1. *Deleting files:* "DEL filename" will remove a file from a diskette, e.g., "DEL C:STUFF.BAS" will remove the file "STUFF.BAS" from the "C" drive. The command "DEL B:*.*" will remove all files from the current directory of drive "B".

2. *Renaming files:* "REN oldfilename newfilename" will change the indicated filename. If a file with "newfilename" already exists, the command will be aborted with an error message.

3. *Printing files:* A "quick and dirty" method to print files is the command "COPY filename LPT1", where LPT1 is a parallel printer on port #1. Another way to print a file will be to issue the command: COPY filename PRN". If multiple files need to be printed, or if line spacing is important, use PRINT command (you will need the MS-DOS floppy disk-1 in drive "A:") "PRINT filename1 filename2 .... filenameN", where N may be at most 32. Many options, like page length, auto form feed, etc., can be specified (see MS-DOS Reference Manual, pp. 11.270-11.284).

4. *Viewing text files:* "TYPE filename" will display the contents of a text file on the screen. This is useful for a fast look at a FORTRAN source code file. Wildcard characters ("*" or "?") are not allowed with this command.

3. WATFOR-77 ON THE MICROCOMPUTER

3.1 General Considerations

1. There are two versions of the WATFOR-77 compiler: WATFOR77.EXE and WATFOR87.EXE. The latter version requires the presence of an Intel 8087 numeric coprocessor, which is used to perform both integer and floating point arithmetic. The former version uses software routines to implement these arithmetic functions. WATFOR77.EXE may be run with or without the numeric coprocessor; however, this chip (if it were present) would not be used by WATFOR77.EXE.

2. All of the WATFOR-77 software is under a campus site license. Accordingly, it may be copied by Lehigh University faculty, staff, and students for use on campus only.

3. A two disk set containing the essential components of WATFOR-77 has been prepared to meet the needs of Engineering-1. The first disk contains the WATFOR-77 compiler, WATCOM editor (WEDIT), and associated files. This disk is bootable. The second disk contains the WATFOR-77 and GKS (Graphical Kernel System) library files, as well as some utility programs which allow graphics output to be printed on a dot-matrix or laserjet printer. The autoexec file on the first diskette automatically tells the user how to start WATFOR-77.

4. A version of WATFOR-77 for microcomputers with hard disks is also available. This three disk set contains detailed on-line installation instructions and an automatic installation utility to help the user install WATFOR-77 onto a hard disk system. This set of disks is available for copying at the following public microcomputing sites: the central site user's area, the Fairchild-Martindale campus library, the Media Center, the Linderman Library, and the Educational Technology Center. (For assistance with installing WATFOR-77 onto a hard disk system, contact User Services, room 194 of the Fairchild-Martindale Computing Center, building 8B, phone 83990.) Also available at these locations are two documents, written by the Computing Center, entitled "Installation and Use of WATFOR-77" and "Description of WATFOR-77 Files." Included in the first of these documents is a complete description of the various versions of WATFOR-77 available at Lehigh for faculty, staff, and student use.

5. WATFOR-77 includes a library of graphics subroutines, namely WATCOM GKS. These subroutines adhere to the Graphical Kernel System (GKS) Standard established by the International Standards Organization (ISO). WATCOM GKS allows you to write graphics programs that are device independent; i.e. are compatible with a large variety of hardware.

6. Documentation for WATFOR-77 from WATCOM publications includes:

* WATFOR-77 User's Guide for the IBM PC with DOS (Third Edition), and Supplement. This book covers the basic operation of WATFOR-77, file and device handling, data types supported, compiler options, the WATFOR-77 debugger and special configuration options.

* WATFOR-77 Language Reference Manual (First Edition). This book gives a detailed description of WATFOR-77 implementation of FORTRAN. It is organized by topics. However, one chapter, "FORTRAN Statements," is organized alphabetically.

* WATCOM Editor User's Guide for the IBM PC with DOS, (Third Edition or Second Edition plus Supplement). This book is a complete description of the general purpose editor that accompanies all WATCOM language products. It consists of a tutorial guide, followed by a reference section.

* WATCOM GKS Graphics Tutorial and Reference Manual (Second Edition), and Addendum. This book combines a tutorial on WATCOM GKS with complete description of all graphics routines.

3.2 FORTRAN Programming and WATFOR-77
A few comments are in order concerning computer programming in general and the operation of WATFOR-77 in particular.

1. The level at which a computer functions internally is quite primitive in comparison with the level at which human beings think about and solve problems. Forcing people to work at the level of the machine would generally interfere with rather than aide the problem-solving process. In order to bridge the gap between the level at which people think about problems and the

10

primitive level at which the machine operates, various software tools have been developed, among them "high level languages" such as FORTRAN. A language such as FORTRAN allows one to express the method to be used to solve a problem (i.e., the "algorithm") in a relatively abstract fashion, using statements which resemble a mixture of natural language (e.g., English) and mathematical notation. Given such a language for describing algorithms, two problems remain: one needs a way to enter the description of the algorithm (e.g., FORTRAN program) into the computer, and one needs to "translate" statements written in the high-level language into the more primitive statements which the machine is able to carry out (i.e., into "machine instructions"). Entering the program is accomplished by a piece of software called an "editor," and the translation of the program into machine instructions is accomplished by a piece of software called a "compiler." WATFOR-77 includes both a general-purpose text editor (WEDIT) and a FORTRAN compiler. (Note that the term "FORTRAN" is an acronym for "FORmula TRANslator" -- how appropriate!)

2. At Lehigh, WATFOR-77 is set up so that the editor and compiler function as a single entity rather than as two separate pieces of software; this makes for a more convenient environment in which to write, test, and debug FORTRAN programs. Entering "WATFOR77" at the DOS prompt will cause both the FORTRAN compiler and text editor to be loaded into the computer's memory and made available for use. FORTRAN programs can then be entered and/or modified using the text editor; once a program has been entered, it can be made to execute using the "RUN" command (to be described later).

3. Getting a FORTRAN program to run actually involves three separate steps. The program must first be compiled into machine instructions. If the program makes use of any functions or subroutines contained in FORTRAN "libraries" (for example, GKS graphics subroutines), these library routines must be "linked" into the set of machine instructions which resulted from compilation. This linking results in a largely self-contained list of instructions which can be carried out by the machine. When the machine carries out these instructions, the FORTRAN program is said to "execute." This compile-link-execute sequence is automatically performed by WATFOR-77 when the "RUN" command is given.

4. The WATCOM text editor, WEDIT, can be used to edit any kind of text file; the file need not be a FORTRAN program. Since WEDIT is a general purpose text editor, it can be used apart from the WATFOR-77 compiler; in order to do so, enter "WEDIT" at the DOS prompt. The WATFOR-77 compiler (which compiles, links, and executes FORTRAN programs) can be used apart from the WATCOM text editor by entering "COMPILE" at the DOS prompt (enter "COMPIL77" or "COMPIL87" on hard disk systems). Consult chapter two of the "WATFOR-77 User's Guide" for instructions on using the compiler apart from WEDIT.

> *NOTE THAT IN ENGINEERING-1, THE COMPILER AND EDITOR WILL BE USED TOGETHER; THUS, AS A GENERAL RULE "WATFOR77" RATHER THAN "WEDIT" OR "COMPILE" WILL BE ENTERED AT THE DOS PROMPT.*

3.3 Using the WATCOM Text Editor

1. Recall that entering "WATFOR77" at the DOS prompt will load both the WATFOR-77 compiler and WATCOM text editor into the computer's memory. Entering "WEDIT" at the DOS prompt will load only the editor. After the editor starts you will see a "beginning of file" marker and an "end of file" marker, and the cursor will be at the bottom of the screen on the editor's command line. To edit an existing file, type "Edit filename" at the editor's command line, and press the RETURN key. Entering "WATFOR77 filename" (or "WEDIT filename") at the DOS prompt will start the editor and begin editing the specified file, thereby combining the above two steps into one.

Note that when the editor is used in conjunction with the WATFOR-77 compiler, a file extension of "FOR" is assumed if no extension is specified; thus, entering "WATFOR77 TEST" at the DOS prompt or entering "Edit TEST" at the editor's command line will result in the editing of a file named "TEST.FOR". (When WEDIT is used apart from the WATFOR-77 compiler, no file extension is assumed.)

2. Type "EXit" and press RETURN at the command line in order to leave the editor and return to DOS, saving any additions or modifications made to the file being edited. If the file being edited does not already have a name, a name can be specified with

"EXit filename". To leave the editor and return to DOS without saving the file, use the "QUIT" command. "Put" or "Put filename" will save the file to disk without leaving the editor. When the editor is used in conjunction with the compiler, a file extension of "FOR" is assumed if none is given when specifying the name under which the file is to be saved.

3. Enter "Help" at the command line to see a list of valid editor commands. Most editor commands can be abbreviated; for example, the "Edit" command can be shortened to "Edi", "Ed", or "E". The shortest acceptable abbreviation is indicated by capital letters, both in this document and in the list obtained with the "Help" command; thus, the "EXit" command can be abbreviated to "EX" but not to "E" -- after all, "E" is an abbreviation for "Edit".

In order to obtain help on a particular editor command, enter "Help command" at the command line; thus, "Help EXit" will provide information on the "EXit" command. When "<more>" or "<hold>" appears in the lower right corner of the screen, simply press the RETURN key in order to see more information or to continue editing, respectively.

Some of the editor's functions are performed via commands entered at the command line; other functions are performed via the computer's function keys. Press function key F10 to obtain a list of the functions which the editor assigns to each function key; then press the RETURN key to continue editing.

4. Pressing the function key F9 will move the cursor from the editor's command line to the editor's full screen area, where the contents of the file being edited are displayed; pressing F9 again will move the cursor back to the command line. Every time F9 is pressed, the cursor moves alternately between these two areas of the screen.

If the "Input" command is given at the command line, the cursor will move into the full screen area and a new, blank line will appear in the file being edited. The user can then enter text on this new line. Pressing RETURN will cause another blank line to appear below the line just entered. This mode of entering new lines into the file is referred to as "Input" mode. Pressing F9 will terminate input mode and return the cursor to the command line. Input mode is also terminated upon moving to a different

line in the file via the up- or down-arrow keys. When this happens, the cursor remains in the full screen area, but pressing RETURN no longer creates a new line; it simply moves the cursor to the beginning of the next existing line. Should input mode be terminated accidentally, simply press F9 to return to the command line, and give the "Input" command again.

When the cursor is in the full screen area, the line on which the cursor is positioned is referred to as the "current line." When the cursor on the command line, the current line is highlighted. Although input mode is well suited for entering a group of new lines into a file, a single new line is more easily entered by pressing the function key F5. Pressing F5 inserts one new, blank line after the current line and positions the cursor on this new line, regardless of the cursor's original position.

5. Note that when editing an existing file, the editor works with a copy of the file rather than the original. This copy is stored in an area of the computer's memory which is referred to as an "editor workspace." When the file is saved to disk via the "EXit" or "Put" commands, the contents of this workspace replace the version of the file stored on disk; thus, the editor does not alter the disk version of the file being edited until the file is actually saved.

It is sometimes useful to edit several different files simultaneously; the WATCOM editor has this capability. Simultaneous editing is accomplished by storing a copy of each file in a different workspace; however, only one workspace is displayed at one time. The workspace whose contents are currently displayed in the editor's full screen area is called the "current workspace"; if only one file is being edited, the phrase "current workspace" necessarily refers to this one file.

In order to distinguish between different workspaces, each workspace is given a name, which is usually the same as the name of the file stored in the workspace. An arbitrary name can be assigned to the current workspace with the command "Name workspacename". A list of the names of all the editor's workspaces can be obtained with the "SHow" command; the current workspace is indicated by the ">" character. The function key SHIFT/F10 (which is equivalent to entering "Edit" at the command line and pressing RETURN) will cause the workspace following the

current workspace on the above list to become the current workspace; repeatedly pressing SHIFT/F10 will display each workspace in turn in the editor's full screen area.

6. Entering "Get filename" at the command line will cause the file specified to be inserted into current workspace immediately after the current line.

Note that there are fundamental differences between the "Edit" command and the "Get" command. Suppose that during a single editing session the command "Edit filename" is given several times, each time with a different filename. Each time this command is given, a new editor workspace will be created; the workspace will be given the name of the specified file and will contain a copy of that file. Suppose, on the other hand, that during a single editing session the command "Get filename" is given several times, each time with a different filename. Each time this command is given, <u>no</u> new work space will be created; rather, the specified file will be inserted into the current workspace, and the name of the current workspace will remain unchanged.

<u>"Edit filename" thus creates and names a new workspace, whereas "Get filename" simply inserts a file into the current workspace.</u>

7. Each function key is used by the editor for at least two purposes. For example, F10 provides a help screen which summarizes the uses of the function keys, whereas SHIFT/F10 (i.e., hold down the SHIFT key and press F10) is equivalent to entering "Edit" at the command line and pressing RETURN. In WATCOM's documentation, functions SHIFT/F1 through SHIFT/F10 are referred to as F11 through F20; thus, Fn+10 denotes SHIFT/Fn, where n = 1, 2, ..., 10. Some of the more useful function keys are briefly described below.

F1: Page Up

F2: Page Down

F3: Line Up

F4: Line Down

F5: Line Insert (Inserts a new line immediately after the current line.)

F6: Line delete (Deletes the current line.)

F7: Select/deselect (in preparation for a cut and paste operation).

F8: Cut

F9: Toggle Full Screen Area/Command Line

F10: Function Key Help Screen

F16: Undelete Line (Brings back the last line deleted by F6.)

F18: Paste

F20: Edit

8. WEDIT automatically maintains a line numbering system. The line numbers are not displayed during editing. However, they may be easily referenced from the command line. For example, to locate line 48, and make it the current line, type "48" on the command line, and press RETURN.

9. WEDIT uses special symbols for certain lines. The current line is referenced by a "."; the last line is referenced by a "$". A "+" indicates the line after the current one and a "-" indicates a line before the current one. Numbers may be appended to these last two symbols; for example, "+10" refers to the tenth line after the current line.

10. Line number ranges are indicated by "i,j", where "i" and "j" may be numbers or special symbols. ".,$" indicates the range from the current line to the end of the current workspace. WEDIT also employs the symbol "*" to refer to all lines in the current workspace.

11. "i,j Delete" will delete all the lines in the range specified by "i,j". Omission of the range will cause the current line to be deleted. The command "*Delete" will delete all lines in the current workspace.

12. The command "/string/" will search the current workspace for the first line containing the specified string of characters; for example, entering "/FORTRAN Compiler/" at the command line will cause the editor to search for the first line which contains "FORTRAN Compiler". Note that the editor's string-searching is "case sensitive," meaning that whether the search string contains upper or lower case characters will effect the results of the search; thus, the command given above would <u>not</u> find the strings "fortran compiler" or "Fortran Compiler". The command "+/string/" causes the editor to search for the first line after the current line which contains the specified string; the command "-/string/" causes the editor to search backwards through the current workspace starting with the line immediately before the current line.

When used as a search string, the symbol "//" refers to the last search string specified; thus, one can give the command "/string/" to find the first occurrence of the specified string and then repeatedly give the command "+//" to find all subsequent occurrences. In this context, it is useful to know that the commands "?" and "=" will recall and re-execute, respectively, the last command given at the editor's command line.

Note that if the "/" character is itself part of the search string, it must be preceded by a "%". For example, the command "/1%/2/" will search for the first occurrence of the string "1/2". The construction "%/" is one of several "meta-characters" employed by the WATCOM editor.

13. "i,j Change/string1/string2/" will, in the designated line range, change the first occurrence of "string1" on each line to "string2". If no range is indicated, only the current line will be affected. "ChangeN/string1/string2" will change the "Nth" occurrence of "string1" on the current line. The use of "*" instead of a whole number will result in all occurrences of "string1" on each line in the designated range being changed. Lastly, "*Change*/string1/string2" will change every occurrence of "string1" throughout the workspace. For example, ".,$

Change/sat/isat" will change the first occurrence of "sat" on each line to "isat" in the range from the current line to the end of the workspace. The command ".,$ Change*/sat/isat" will change every occurrence of "sat" to "isat" in the designated line range.

14. "DIrectory" will list the files on the current drive. This command takes all the usual MS-DOS modifiers: wildcards, drive designations, and path specifications.

15. "ERase filename" deletes the selected file(s) from the disk. Wildcards, drive designations, and path specifications are allowed.

16. The "SYStem" command will temporarily leave the editor and return to MS-DOS; however, the WATCOM editor, WATFOR-77 compiler (where applicable), and all editor workspaces are retained in the computer's memory. Any number of DOS commands may then be entered at the DOS prompt. The DOS command "EXIT" will return the user to the editor and (where applicable) the compiler, with all of the editor's workspaces intact.

Note that if only one DOS command is to be executed, it is more convenient to enter "SYStem doscommand" at the editor's command line. After the specified DOS command is executed, press the RETURN key to continue editing.

17. It is possible (to some extent) to tailor the WATCOM editor to suit the user's personal needs. Whenever the editor is started up in conjunction with the compiler (via entering "WATFOR77" at the DOS prompt), any editor commands contained in the file "PROFILE.FOR" are automatically performed, just as though they had been entered at the editor's command line. Whenever the editor is started up apart from the compiler (via entering "WEDIT" at the DOS prompt), editor commands contained in the file "PROFILE.EDI" are automatically performed. Any commands which the user gives at the beginning of every editing session can be put in the appropriate profile file, and these commands will be executed automatically. For example, the command "TABset i j k ...", which sets the editor's tab-stops to the specified columns, has already been put into both profile files; the tabs have been set to columns 7, 12, 17, 22, ..., 72. The command "BELL 72" has also been put into both profile files; this command causes the computer's bell to ring whenever the cursor moves from

column 72 to column 73. These commands have been used to set up the editor for entering FORTRAN programs (FORTRAN statements must be contained in columns 7 - 72).

It is also possible for the user to assign functions to the function keys via the command "PF n text", where "n" is a whole number from 1 to 10, and "text" is the text to be produced whenever the user enters ALT/Fn; for example, consider the command "PF 10 HELP<CR>". After giving this command, pressing ALT/F10 at the command line will produce the same results as typing "HELP" and pressing the RETURN key. If the command "PF 10 HELP<CR>" is placed in the editor profile files, then ALT/F10 will automatically be defined to perform as described above.

3.4 Using WATFOR-77 Compiler

1. Suppose that "WATFOR77" has been entered at the DOS prompt, and the WATCOM editor and WATFOR-77 compiler have been loaded into the computer's memory. Suppose also that a FORTRAN program has been newly entered during the current editing session; the workspace containing the program (presumably the current workspace) may not yet have a name. A name can be given by entering "Name workspacename" at the editor's command line. After naming the workspace, it is wise to save the workspace to disk with the "Put" command. (Note that the "Put" command does not name the workspace.)

Once the current workspace has been named and saved to disk, the FORTRAN program contained in it can be compiled, linked, and executed by entering "RUN" at the editor's command line. (Recall that compiling, linking, and executing the FORTRAN program are accomplished by the WATFOR-77 compiler.) If the program contains no syntax errors (i.e., if there are no mistakes in FORTRAN "grammar"), the program will be executed immediately after it has been compiled and linked. Any output which is written to Unit 6 (the default unit number for output) will appear on the screen, and any input which is read from Unit 5 (the default unit number for input) may be entered at the keyboard. When the program has finished executing, "<hold>" will appear in the lower right corner of the screen; press the RETURN key to return to the editor and resume editing the FORTRAN program.

19

Note that if one attempts to "RUN" a program contained in an un-
named workspace, the message "no file name" will appear in the
line above the command line, and the program will not be com-
piled. This message indicates that a workspace must be named
before the program contained in it can be run.

In addition to compiling, linking, and executing a FORTRAN
program, the "RUN" command creates what is called a "listing
file". This file is stored in the current directory of the
default disk drive. It has the same primary file name as the
workspace, but has an extension of "LST"; for example, if the
workspace is named "TEST.FOR", the "RUN" command will create a
listing file named "TEST.LST". The listing file contains a copy
of the original FORTRAN program, as well as some additional in-
formation which is generated during the compilation, linking, and
execution of the program. All non-blank, non-comment lines in
the original program are numbered; these line numbers appear to
the left of each effected line in listing file. At the end of
the listing file are some statistics concerning how much time was
needed to compile and execute the program, how much memory was
used, etc.

There are at least two ways to examine this listing file while
using the WATFOR-77 compiler/editor. If the workspace containing
the FORTRAN program is named "name.FOR", the command "SYStem TYPE
name.LST" will type the listing file, just as if the "TYPE" com-
mand had been given at the DOS prompt; press RETURN in order to
resume editing. Here is a more advanced way to examine the list-
ing file: enter "Edit name.LST" at the editor's command line;
this will create a new editor workspace containing the listing
file, which can then be easily examined using the PgUp, PgDn,
up-arrow, and down-arrow keys. Note that the original FORTRAN
program is still in the computer's memory in a separate
workspace. Repeatedly pressing SHIFT/F10 will alternately dis-
play the program file and the listing file in the editor's full
screen area. Be sure to "QUIT" from the workspace containing the
listing file before running the program again; otherwise, the
next "Edit name.LST" command will display an outdated copy of the
listing file.

2. If the FORTRAN program contains syntax errors, error messages
will be sent to the screen during compilation, and the program
will not be executed. The compiler tries to the best of its

ability to locate and describe all syntax errors contained in the program; however, this requires a level of intelligence which most compilers are not yet able to muster. For this reason, compiler error messages most often give one a "feel" for where the true problem lies, rather than a precise description of the nature and location of the problem.

Note that the editor numbers every line in the original program, whereas the listing file numbers only lines which contain FORTRAN statements; thus, the editor's line numbers are different from the statement numbers which appear in the listing file! The compiler error messages which are sent to the screen during compilation may refer to "line n", where n is some whole number; this line number refers to the editor's line number in the original program and not the listing file's statement number. Recall that entering "n" at the editor's command line will make line n become the current line; this provides a convenient way to examine the lines specified in the compiler's error messages. Error messages sent to screen during execution may refer to "statement n"; this refers to the statement number in the listing file, not the line number in the editor's workspace.

When compiling a program which contains syntax errors, the compiler also sends error messages to the listing file. The compiler tries to place these error messages immediately below the line which it believes to be the cause of the problem, and points (with a "$") to what it believes to be the offending portion of the line. This feature makes the listing file particularly valuable when trying to debug longer programs containing many syntax errors.

3. Entering "RUN" at the editor's command line is the most basic way to compile, link, and execute the FORTRAN program contained in the current workspace. For the convenience of the user, several other ways to run a program have been provided with the WATFOR-77 software distributed at Lehigh. WHEN THE CURSOR IS ON THE COMMAND LINE, the function keys ALT/F1, ALT/F2, and ALT/F3 will also compile, link, and execute the program in the current workspace, with the following differences. ALT/F1 creates no listing file, thus providing a slightly faster way to run, a way

which does not clutter up the disk with ".LST" files. ALT/F2 does generate a listing, but sends the listing to the screen rather than to disk; thus, ALT/F2 provides a convenient way to examine the listing produced by the compiler (and also does not clutter up the disk). ALT/F3 sends both Unit 6 output and the compiler listing to the listing file (on disk) rather than to the screen; ALT/F3 is best suited for creating a file which can be printed and turned in to the instructor for an assignment.

These function key definitions are automatically made whenever the editor/compiler starts up (the file "PROFILE.FOR" contains the appropriate "PF" commands). The function key F10 displays the functions assigned to user-programmable function keys as well as the standard editor function keys.

3.5 Large Programs and Memory Limitations in WATFOR-77

1. When working with large FORTRAN programs, WATFOR-77 users may occasionally "bump their heads" on the upper limits of the personal computer's resources. It is important for those who process large FORTRAN programs with WATFOR-77 to understand the nature of these limitations and to know how to get around them.

There is an upper limit to the size of files which can be edited by the WATCOM editor as well as a limit on the size of files which can be compiled with the WATFOR-77 compiler. If the user tries to edit a file whose size exceeds the capabilities of the WATCOM editor, the entire file will not be loaded into the editor's workspace; some portion at the end of the file will be cut off (from the editor's copy of the disk version of the file). If the user tries to compile a file which is too large, compilation will abort with an error message such as "dynamic memory exhausted" or "object memory exhausted." The exact limits vary somewhat depending on the total amount of available memory in the computer, on how WATFOR-77 is configured, and on how WATFOR-77 is used.

2. Under no circumstances can the WATCOM editor edit files larger than 64K bytes (i.e., 65,536 characters). In actual practice, the upper limit is usually smaller than this. When the

WATCOM editor is used apart from the compiler (via entering WEDIT at the DOS prompt), the upper limit should be in the neighborhood of 61,000 characters. When the editor is used in conjunction with the compiler (via entering WATFOR77 or WATFOR87 at the DOS prompt -- assuming that the software has been configured to function in the interactive mode), the upper limit should be in the neighborhood of 50,000 characters (slightly higher for WATFOR87 than WATFOR77). When editing a file, the exact amount of free space remaining (number of characters) is displayed on the line above the editor command line; it is the right-most of the three numbers in parentheses. It may be necessary to press the RETURN key once in order to cause these numbers to be displayed.

How can a FORTRAN program larger than 64K bytes be created using the WATCOM editor? The program can be split into pieces, where each piece contained in a separate file and each file is smaller than 64K bytes. How are these separate pieces combined to form a single FORTRAN program? This can be accomplished via the C$INCLUDE compiler option; that is, whenever the compiler encounters a comment line of the form

        C$INCLUDE filename

the specified file is included into the source code of the program being compiled.

Consider the following simple example. Suppose that a large program is contained in three separate files called PART1.FOR, PART2.FOR, and PART3.FOR, and suppose that a fourth file called MAIN.FOR consists of these lines:

```
        PROGRAM SAMPLE

      C$INCLUDE PART1.FOR
      C$INCLUDE PART2.FOR
      C$INCLUDE PART3.FOR

        STOP
        END
```

The entire program can be compiled, linked, and executed by running MAIN.FOR; the compiler will read from the files PART1.FOR, PART2.FOR, and PART3.FOR where indicated by the C$INCLUDE compiler option.

NOTE: WATCOM claims to have a disk-based version of WEDIT, called DEDIT, that overcomes the 64K byte limit. Interested users should direct inquiries to WATCOM. Note also that there are some good text editors for the PC available in the public domain; some of these, such as MICRO-EMACS, can edit very large text files.

3. Occasionally when WATFOR-77 tries to compile a large FORTRAN program, compilation aborts with the error message "dynamic memory exhausted." This means that for some reason, there is not enough memory available to the WATFOR-77 compiler to hold the intermediate results of compilation; when this is the case, compilation cannot be completed unless special action is taken.

This situation is more likely to occur when the WATFOR-77 compiler is used in conjunction with the WATCOM text editor than when the compiler is used alone. The reason is that when the compiler and editor are configured to function as a unit, the compiler's dynamic memory and the editor's workspace apparently share the same portion of the computer's memory. "Dynamic memory" refers to a portion of memory which is set aside to hold, among other things, the intermediate results of compilation (e.g., the compiler's symbol table). Under no circumstances can the amount of the compiler's dynamic memory exceed 64K bytes.

If compilation aborts with the error message "dynamic memory exhausted" when the compiler is used in conjunction with the integrated text editor, the following steps will in all likelihood remedy the problem.

(a) Enter "Put" or "Put filename" at the editor command line in order to save the program to disk.

(b) After saving the program, clear the editor workspace by entering "* Delete" at the editor command line. This should free enough (dynamic) memory to allow compilation to run to completion.

(c) In order not to confuse WATFOR-77, rename the editor workspace so that it will have a different name than the name of the program which has been saved to disk. For example, if the program has been saved to disk as "ABC.FOR", it would be safe to rename the editor workspace to "X.FOR" by entering "Name X" at the editor command line.

(d) Compile, link, and execute the program from disk by entering

        RUN/option1/option2/.../optionN filename

at the editor command line, where "/option1", ..., "/optionN" are any valid compiler options (such as /LIST and /TYPE) and "filename" is the name of the program as saved to disk in step (a). For example, to run the program saved to disk as "ABC.FOR" and direct the listing to the screen, enter

        RUN/TYPE ABC

at the command line.

(e) Should it be necessary to make changes to the program, enter "Edit filename" at the command line (e.g., "Edit ABC"). Use the "Edit" command rather than the "Get" command, since "Edit" gives the workspace a name (the same as the filename specified) whereas "Get" does not. After making the necessary changes, run the program by repeating steps (a) through (d) above.

Approximately 2K bytes of additional dynamic memory can be gained over the above method by using the compiler separate from the WATCOM text editor. This may be accomplished by entering

        COMPILE /option1/option2/.../optionN filename

at the DOS prompt, where "/option1", ..., "/optionN" denote valid compiler options and "filename" is the name of the FORTRAN program to be compiled. (Hard disk users should enter COMPIL77 or COMPIL87 instead of COMPILE; only dual floppy users should enter COMPILE.) Note that in this context it is essential to put a space between COMPILE and any compiler options which are

25

listed; the compiler options themselves must not be separated by spaces. Note that this method of using the compiler also permits one to compile FORTRAN programs which exceed the 64K limit on file size imposed by the WATCOM editor.

Included with the complete WATFOR-77 software package is a utility program called CONFIG.COM. This utility program allows the user to tailor WATFOR-77 to suit individual needs. In particular, CONFIG.COM allows the user to set the number and size of file buffers as well as the size of the stack used by the WATFOR-77 compiler. Note that increasing the default file buffer space and/or stack size will decrease the amount of dynamic memory available by an essentially equal amount; similarly, decreasing file buffer space and/or stack size will increase the amount of dynamic memory available.

4. Occasionally when WATFOR-77 tries to compile a large FORTRAN program, compilation aborts with the error message "object memory exhausted." This means that there is not enough memory available to contain the final results of compilation (e.g., object code, data); when this is the case, compilation cannot be completed unless some special action is taken.

"Object memory" refers to that portion of memory which is set aside to hold the compiled program. The maximum amount of object memory permitted is limited only by the total amount of available memory in the PC; that is, the upper limit varies depending upon how much memory the machine contains and how much of that memory has already been reserved for use by other PC programs (such as the operating system and any memory resident programs).

If compilation aborts with the error message "object memory exhausted," one possible solution is to use a PC which contains more memory. The MS-DOS command CHKDSK (found on MS-DOS disk I) will display the total amount of memory in a PC as well as how much of that memory is available for use (which is the more relevant quantity in this case). Note that all of the PC's at Lehigh's public microcomputing sites contain at least 512K bytes of memory.

If the computer contains a large amount of memory, but comparatively little of that memory is available for use, then it may be fruitful to free some of the memory which has been committed to

26

other purposes. For example, a virtual disk (or "RAM" disk, i.e., a portion of memory which has been set up to behave like a very fast disk drive) occupies memory space which could be freed to provide more object memory. Similarly, unloading any memory resident programs (such as TURBO Lightning or Sidekick) which have been installed would free additional memory for use as object memory.

If the computer contains a large amount of memory, most of which is already available for use, then it may be possible to free some memory for use as object memory via the /DYNAMIC=n compiler option. This compiler option limits the maximum amount of dynamic memory available to "n" bytes, where "n" may be a whole number of bytes or a multiple of 1024 bytes (which is indicated by a suffix of "K"). For example, entering

        RUN/DYNAMIC=100

at the command line of the integrated compiler/editor will limit the maximum amount of dynamic memory to 100 bytes, whereas entering

        RUN/DYNAMIC=4K

will limit the maximum amount of dynamic memory to 4096 bytes. By default, the maximum amount of dynamic memory is 64K. In some cases, reducing the amount of dynamic memory allocated can free enough memory for use as object memory to allow the program to compile successfully. There is obviously a balance to be maintained here, since allocating too little dynamic memory could cause compilation to abort with the error "dynamic memory exhausted." If this should happen, refer to the previous section! (The "Object/Dynamic bytes free" statistic found at the end of the listing file may be of some use when adjusting the /DYNAMIC=n compiler option.)

If none of the above eliminates the error "object memory exhausted," try reducing the size of any large arrays wherever possible. Since data as well as compiled code is stored in object memory, this may solve the problem.

4. SOME HELPFUL HINTS FOR ENGINEERING-1

The microcomputer user must be aware of a number of command statements and what they do. These are listed below according to operational categories.

4.1 MS-DOS Commands

These commands may be given when the MS-DOS prompt "B:\>" is on the screen.

DIR   Lists the names of the files in the
                            directory of the disk in the
                            default drive (B).

DIR A: /P   Lists the names of the files on the
                            disk in drive A, and pauses after
                            every screen of output.

DIR B: Lists the names of the files on the
                            disk in drive B.

TYPE SAMPLE1.LST   Displays on the screen the contents
                            of the file named "SAMPLE1.LST"
                            on the disk in the default drive.

DEL SAMPLE1.LST   Erases the file named "SAMPLE1.LST"
                            from the disk in the default drive.

REN DATA CIVIL.DTA   Renames the file named "DATA" on
                            the disk in the default drive to
                            the new name, "CIVIL.DTA".

FORMAT B: Formats the disk in your drive B.
                            You must format a new disk before
                            using it for the first time.
                            (IMPORTANT: An ENG-1 WATFOR-77
                            diskette No.1 or MS-DOS Disk-1 must
                            be in drive A before executing this
                            command.)

```
COPY A:PROGA.FOR B:PROGB.FOR    Copies the file called "PROGA.FOR"
                                on the disk in drive A to a file
                                called "PROGB.FOR" on the disk in
                                drive B.

COPY B:PROGR2.FOR LPT1:         gets the file called "PROG2.FOR"
COPY B:PROGR2.FOR PRN           on the disk in drive B and prints
                                the contents on a dot-matrix
                                printer.  (You realize, of course,
                                that the microcomputer used to do
                                this must be physically wired to
                                the printer.)
```

To copy the entire contents of one diskette onto another dis-
kette, you can go through the following steps.

> 1) Get an MS-DOS (#1) disk from the consultant on duty at a
> public microcomputing site.

> 2) Place it in drive A and boot the system.

> 3) Type "DISKCOPY A: B:" and remove the MS-DOS disk from
> drive A.

> 4) Place the source diskette in drive A and the target dis-
> kette in drive B and depress the return key. (The diskette
> in drive B will first be formatted <u>and</u> then all of the files
> on the disk in drive A will be copied onto the disk in drive
> B.   REMEMBER: When a DISKCOPY command is invoked as
> described above, all the contents, if any, of the diskette
> in drive B will be lost.

4.2 <u>Additional</u> <u>Scenario</u>
The following situations apply when the Engineering-1 WATFOR-77
Diskette No.1 is located in the "A" drive, and WATFOR-77 Diskette
No.2 is in "B" drive.
Situation: Have a program called TEST1.FOR with WRITE(*,15)

> Then if you do:

ALT/F2 at the editor's command line

Compilation and output will appear on the screen.

However, if you do:

ALT/F3 at the editor's command line.

Nothing will appear on the screen. Compilation and output
will be put into a file called TEST1.LST.

Situation: Have a program called TEST1.FOR with
OPEN(6,FILE='RESULT.LST')

and either

WRITE(*,16)
or
WRITE(6,16)

Then if you do:

ALT/F2 at the editor's command line.

Compilation listing will appear on the screen, but output
be in a file called RESULT.LST.

If you do:

ALT/F3 at the editor's command line

Nothing will appear on the screen. Compilation listing will
be in a file called TEST1.LST, and the output will be in the
file called RESULT.LST.
