Method for Prioritizing Urban Pesticides for Monitoring California's Urban Surface Waters

Introduction

A key mission of the California Department of Pesticide Regulation (DPR) Environmental Monitoring Branch (EM) is to monitor pesticide residues in surface waters with urban runoff inputs. Recent monitoring efforts have identified urban runoff as a major contributor of pesticides to California surface waters (Ensminger et al., 2012). Pesticide use is in constant flux, as new active ingredients are introduced into the market place, while others are placed under regulatory restrictions through changes in labeling or cancellation. This creates a challenge for regulators to determine high priority pesticides that have the greatest potential for contaminating surface waters through offsite transport. The purpose of this evaluation was to establish a systematic approach of prioritizing pesticides based on pesticide use and aquatic toxicity data to focus our monitoring efforts in urban areas.

Use Types and Chemical Groups Excluded

It is unrealistic to evaluate every registered pesticide. However, a system can be developed that is broad in scope to include pesticides that have potential to threaten water quality of California surface waters. Pertinent pesticide information was compiled using the International Union of Pure and Applied Chemistry (IUPAC) pesticide properties database and

the Pesticide Action Network (PAN) pesticide database. Pesticides of use types (A) or chemical groups (B) with low probability to impair surface water quality were screened and removed from the prioritization scheme (Table 1 and 2, respectively). These AIs are typically lacking associated benchmarks or sufficient aquatic toxicity data. Pesticides with additional classifications (i.e. insecticide, herbicide) not included in Table 1 or Table 2 were not assigned a screening code and advanced through the prioritization process. There were 216 AIs designated as type A (Appendix 1) and 164 as type B (Appendix 2). These pesticides will not be evaluated further for prioritization regardless of use patterns. However, they may be incorporated into future evaluations if changes in label use or new toxicity information becomes available.

Table 1. Screen “A” – Categories of chemical use excluded from prioritization

Adjvant	Microbiocide	Solvent
Bait	Other product constituent	Sterilant
Breakdown product	Pheromone	Surfactant
Dye	Plant Growth Regulator	Synergist
Fragrance	Repellent	Unclassified
Fumigant	Soap/Surfactant	Wood Preservative

Table 2. Screen “B” – Chemical group excluded from prioritization

Animal derived	Inorganic	Oil – essential
Botanical	Inorganic compound	Oil – vegetable
Fatty acid	Inorganic salt mixture	Petroleum derivative
Fatty acid ester	Microbial	Plant derived
Heavy metal	Micro-organism derived	Soap

Use Pattern Evaluation

Use patterns are complex and dependent on several variables. Pesticide use can vary annually due to variance in pest stressors. While certain pesticides are phased out though

cancellation or label restrictions, others are new on the market and have little associated use data. Urban use determination is complicated by the fact that use by homeowners is not recorded in the statewide pesticide use reporting system (PUR). To estimate pesticide use in urban centers, the PUR database was queried for statewide annual use based on the site codes representative of those applied by pest control operators (PCO) in urban environments: Structural Pest Control (10), Landscape Maintenance (30) and Rights of Way (40). Amount of product applied was converted to pounds of active ingredient prior to the use analysis. Copper containing pesticides, as well as, 2,4-D formulations (acids and esters) were grouped due to similarities in chemistry and toxic endpoints (Appendix 3). The three-year average of the most currently available use data (2009-2011) was ranked and pesticides were designated a use score based on the interval system from the highest total AI amount used to the lowest:

Interval (top %)	Use Score
2	5
4	4
8	3
16	2
70	1

Toxicity Evaluation

The potential toxicity to aquatic species was evaluated using aquatic benchmarks derived by the US EPA Office of Pesticide Programs (OPP) (US EPA, 2010). For pesticides lacking associated benchmarks, OPP benchmark equivalents were used. OPP aquatic life benchmark equivalents are toxicological reference values derived for pesticides that have no benchmark values officially posted on the US EPA OPP “Aquatic Life Benchmark” database. DPR’s surface water program derived the benchmark equivalents based on OPP’s method, using acute

toxicity values for fish, invertebrate, non-vascular and vascular plant endpoints from the International Union of Pure and Applied Chemistry Pesticide Properties database (IUPAC, 2010). Similarly to aquatic benchmarks, the derived equivalents were calculated by using 96-hour LC₅₀ values times a LOC (level of concern). The LOC is set as 0.5 for fish and invertebrates, and 1.0 for vascular and non-vascular plants. The lowest benchmark or equivalent value among all the taxa was given a score using the following brackets:

Effective Dose ($\mu\text{g/L}$)	Toxicity Score
< 0.001	8
0.0011 – 0.01	7
0.011 – 0.1	6
0.11 – 1	5
1.1 – 10	4
11 – 100	3
101 – 1000	2
> 1000	1

Prioritization

A final score was calculated for each pesticide by multiplying use scores by the toxicity score. A total of 313 pesticides with reported urban use between 2009 and 2011 had associated aquatic benchmarks. An additional 173 pesticides had reported use but no toxicity data and therefore not carried through to final prioritization (Appendix 4). These pesticides were scored by use only, which will aid in prioritizing toxicity data needs. The remaining pesticides were ranked based on final score (Table 3). Scores were bracketed based on monitoring priority: very low (1-5), low (6-10), medium (11-15), high (16-20) and very high (>21). Most pesticides fall into the lowest priority bracket (Figure 1), with only 34 pesticides (11%) given a medium, high or very high score. Of these, 25 are either currently or were previously monitored by the Surface Water Program in California urban streams. The analytical laboratory utilized by DPR typically

only reports the parent compound concentration. Therefore, there is no distinction between forms (i.e. esters, salts) of the applied pesticide.

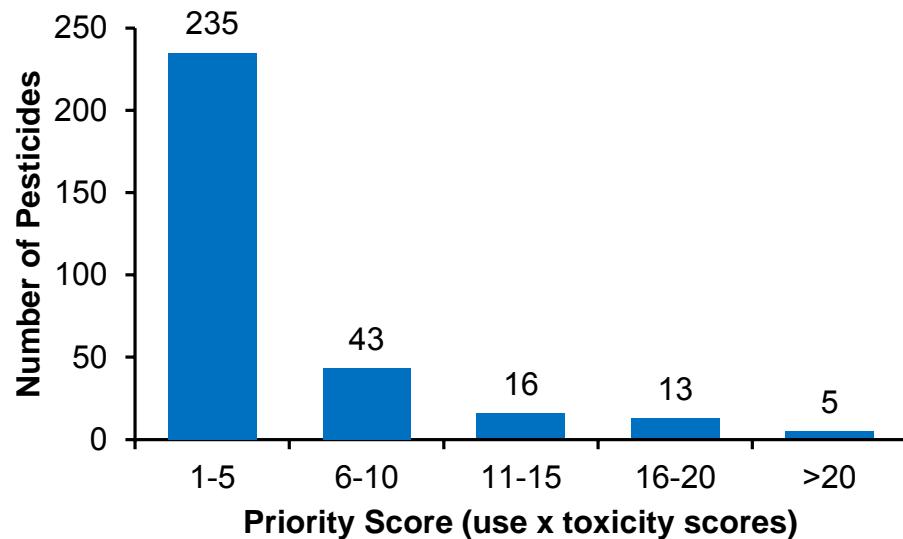

Figure 1. Number of pesticides with final scores in designated brackets

The prioritization model is a tool designed to assist DPR surface water monitoring staff identify pesticides with current high use patterns and associated toxicity. Decisions to add or remove a chemical from future EM sampling plans will be evaluated using professional judgment based on additional information such as previous monitoring results, regional use patterns and physicochemical properties of the pesticide.
