COVARIANT LOCALIZATIONS IN THE TORUS AND THE PHASE OBSERVABLES

G. CASSINELLI, E. DE VITO, P. LAHTI, AND J.-P. PELLONPÄÄ

ABSTRACT. We describe all the localization observables of a quantum particle in a one-dimensional box in terms of sequences of unit vectors in a Hilbert space. An alternative representation in terms of positive semidefinite complex matrices is furnished and the commutative localizations are singled out. As a consequence, we also get a vector sequence characterization of the covariant phase observables.

1. INTRODUCTION

We investigate the problem of the localization of a free quantum particle moving in a one-dimensional box with periodic boundary conditions, adopting the point of view that observables are represented as appropriate normalised positive operator measures. (For that approach, see, e.g. [1, 2, 3, 4]). Therefore, if one chooses the one-dimensional torus \( T \) as the configuration space of the system, then a localization observable \( E \) is a map that defines for any (Borel) subset \( X \subset T \) a bounded operator \( E(X) \) such that, if \( \psi \) is the (vector) state of the system, the number \( \langle \psi | E(X) \psi \rangle \) is the probability that a localization measurement of the particle in that state leads to a result in \( X \). The group of motions of the system is the torus itself that acts on the vector states by means of the geometric representation. The basic requirement for \( E \) to represent localization observable is, therefore, that \( E \) is covariant with respect to this action. Hence a localization observable is a normalized positive operator measure covariant under the geometric action of the torus \( T \).

In the following we call such observables \( T \)-covariant localization observables and we show that they are characterized in terms of sequences of unit vectors in an infinite dimensional Hilbert space. In this framework we select the measures that are projection valued or commutative, and we discuss the problem of the equivalence of such operator measures. As a by product, we also get a representation of

Date: May 18, 2001.
the phase observables, that is, the normalized positive operator measures which are covariant under the shifts generated by the number observable. Our proof is based on a direct application of a theorem due to Cattaneo [5], which generalizes Mackey’s imprimitivity theorem for positive operator measures. Instead, one could use the results of Holevo [6, 7], based also on group theoretical arguments, to obtain a classification in terms of measurable fields of sesquilinear forms, which in the present context can be described as infinite dimensional positive semidefinite complex matrices with diagonal elements equal one. For sake of comparison, we also derive the matrix characterization by direct methods, using only basic analysis and measure theory. This approach has been used in [8] to work out all the phase observables in terms of phase matrices.

2. **T-Covariant localization observables**

Let $\mathbb{T} = \{z \in \mathbb{C} : |z| = 1\}$ denote the one dimensional torus, regarded as a compact (second countable) Abelian group. Let $\mathcal{B}(\mathbb{T})$ be the Borel $\sigma$-algebra of $\mathbb{T}$, $\mu$ the Haar measure on $\mathbb{T}$, $L^2(\mathbb{T}, \mu)$ the Hilbert space of square integrable Borel functions $f : \mathbb{T} \to \mathbb{C}$ and $\mathcal{L}(L^2(\mathbb{T}, \mu))$ the set of bounded operators on $L^2(\mathbb{T}, \mu)$.

The group $\mathbb{T}$ acts on $L^2(\mathbb{T}, \mu)$ via the geometric action

$$[U(a)f](z) = f(az), \quad a \in \mathbb{T}, \quad f \in L^2(\mathbb{T}, \mu), \quad z \in \mathbb{T},$$

which is unitary and continuous with respect to the strong operator topology.

A $\mathbb{T}$-covariant localization observable is a positive normalized operator measure on $\mathbb{T}$, $E : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(L^2(\mathbb{T}, \mu))$, such that, for all $X \in \mathcal{B}(\mathbb{T}), a \in \mathbb{T}$,

$$U(a)E(X)U(a)^* = E(aX). \quad (1)$$

Since the action of $\mathbb{T}$ on itself is transitive, Eq. (1) means that $(U, E)$ is a transitive system of $\mathbb{T}$-covariance based on $\mathbb{T}$ and, hence, $(U, E)$ is described by [5, Proposition 2].

In order to apply the cited result, let us notice the following facts. The stability subgroup of any point of $\mathbb{T}$ is the trivial subgroup $\{1\}$. The trivial representation $\sigma$ of $\{1\}$ acting on $L^2(\mathbb{T}, \mu)$ contains all the (trivial) representations of $\{1\}$ and the corresponding imprimitivity system $(R, P)$ for $\mathbb{T}$ based on $\mathbb{T}$ induced by $\sigma$ acts on $L^2(\mathbb{T} \times \mathbb{T}, \mu \times \mu) \simeq L^2(\mathbb{T}, \mu, L^2(\mathbb{T}, \mu))$ as

$$R(a)\varphi(z_1, z_2) = \varphi(az_1, z_2),$$
$$P(X)\varphi(z_1, z_2) = \chi_X(z_1)\varphi(z_1, z_2),$$
where $\varphi \in L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$, $a \in \mathbb{T}$, $X \in \mathcal{B}(\mathbb{T})$, $z_1, z_2 \in \mathbb{T}$.

Proposition 2 of [5] shows that, given a $\mathbb{T}$-covariant localization observable $E$, there exists an isometry

$$V : L_2(\mathbb{T}, \mu) \to L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu),$$

which intertwines the action $U$ with $R$ and such that

$$E(X) = V^*P(X)V, \quad X \in \mathcal{B}(\mathbb{T}).$$

Conversely, given an intertwining isometry $V$ from $L_2(\mathbb{T}, \mu)$ to $L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$, Eq. (2) defines a positive normalized operator measure $E$ satisfying Eq. (1).

Hence, to classify all the $\mathbb{T}$-covariant localization observables, one has to determine all the isometric mappings $V$ such that

$$VU(a) = R(a)V, \quad a \in \mathbb{T}.$$  

To perform this task, observe that the monomials $e_n$, $n \in \mathbb{Z}$, $e_n(z) = z^n$, $z \in \mathbb{T}$, form an orthonormal basis of $L_2(\mathbb{T}, \mu)$ and the action of $U$ on them is diagonal, that is,

$$U(a)e_n = a^ne_n.$$  

Moreover, the vectors

$$(e_ne_j)(z_1, z_2) = e_n(z_1)e_j(z_2) = z_1^nz_2^j,$$

where $n, j \in \mathbb{Z}$, form an orthonormal basis of $L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$, and the action of $R$ on them is simply

$$R(a)e_ne_j = a^ne_ne_j.$$

It follows that, for any $n \in \mathbb{Z}$, the subspace of $L_2(\mathbb{T}, \mu)$ generated by $e_n$ and the subspace of $L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$ generated by $\{e_ne_j\}_{j \in \mathbb{Z}}$ carry the representation of $\mathbb{T}$, $z \mapsto z^n$.

Hence, if $V : L_2(\mathbb{T}, \mu) \to L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$ is an isometry intertwining $U$ and $R$, for any $n \in \mathbb{Z}$, $Ve_n$ must be in the vector space $\mathcal{S}(\mathbb{T}) \simeq L_2(\mathbb{T}, \mu)$, that is, $Ve_n = e_nh_n$ for some unit vector $h_n$ in $L_2(\mathbb{T}, \mu)$.

Conversely, if $(h_n)_{n \in \mathbb{Z}}$ is a sequence of unit vectors in $L_2(\mathbb{T}, \mu)$, then the mapping $e_n \mapsto e_nh_n$ extends to a unique linear isometry $V : L_2(\mathbb{T}, \mu) \to L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu)$ which intertwines the actions $U$ and $R$ and, by means of Eq. (2), the corresponding operator measure
$E$ is explicitly given by,
\[
\langle e_n | E(X) e_m \rangle = \langle e_n | V^* P(X) V e_m \rangle \\
= \langle V e_n | P(X) V e_m \rangle \\
= \langle e_n h_n | P(X) e_m h_m \rangle \\
= \langle h_n | h_m \rangle \int_X z^{m-n} \, d\mu(z),
\]
where $n, m \in \mathbb{Z}$. Then, if $|e_n\rangle\langle e_m|$ denotes the rank one operator $L^2(\mathbb{T}, \mu) \ni f \mapsto \langle e_m | f \rangle e_n \in L^2(\mathbb{T}, \mu)$ we may thus write, for all $X \in \mathcal{B}(\mathbb{T})$,
\[
E(X) = \sum_{n,m \in \mathbb{Z}} \langle h_n | h_m \rangle \int_X z^{m-n} \, d\mu(z) |e_n\rangle\langle e_m|,
\]
where the double series converges in the weak operator topology. We observe that two sequences of unit vectors $(h_n)_{n \in \mathbb{Z}}$ and $(k_n)_{n \in \mathbb{Z}}$ define the same $\mathbb{T}$-covariant localization observable if and only if $\langle h_n | h_m \rangle = \langle k_n | k_m \rangle$ for all $n, m \in \mathbb{Z}$.

For sake of completeness we also compute the adjoint map $V^* : L^2(\mathbb{T} \times \mathbb{T}, \mu \times \mu) \to L^2(\mathbb{T}, \mu)$. We get
\[
\langle V^* e_n e_j | e_p \rangle = \langle e_n e_j | V e_p \rangle \\
= \langle e_n e_j | e_p h_p \rangle \\
= \begin{cases} 
0, & \text{when } n \neq p, \\
\langle e_j | h_n \rangle, & \text{when } n = p,
\end{cases}
\]
showing that for any $n, j \in \mathbb{Z}$,
\[
V^* e_n e_j = \langle h_n | e_j \rangle e_n.
\]

We now discuss the problem of the equivalence. Two $\mathbb{T}$-covariant localization observables $E$ and $E'$ are equivalent if there is a unitary operator $W : L^2(\mathbb{T}, \mu) \to L^2(\mathbb{T}, \mu)$ such that, for all $a \in \mathbb{T}, X \in \mathcal{B}(\mathbb{T})$,
\[
W U(a) = U(a) W \\
W E(X) = E'(X) W,
\]
Clearly, this definition is the requirement that $(U, E)$ and $(U, E')$ are equivalent as $\mathbb{T}$-covariant systems.

The first condition implies now that for each $n \in \mathbb{Z}$, $W e_n = z_n e_n$, for some $z_n \in \mathbb{T}$. Therefore, the equivalence of $(U, E)$ and $(U, E')$ equals the fact that for each $n, m \in \mathbb{Z}$ and $X \in \mathcal{B}(\mathbb{T})$,
\[
\langle e_n | E'(X) e_m \rangle = z_n z_m \langle e_n | E(X) e_m \rangle,
\]
for some \( z_n, z_m \in \mathbb{T} \). Then, taking into account Eq. (4), two sequences of unit vectors \((h'_n)_{n \in \mathbb{Z}}\) and \((h_n)_{n \in \mathbb{Z}}\) define equivalent \( \mathbb{T} \)-covariant localization observables if and only if for each \( n, m \in \mathbb{Z} \),

\[
\langle h'_n | h'_m \rangle = \langle z_n h_n | z_m h_m \rangle.
\]

Finally, we consider the problem of projection valued measures. Let \( K \) be the closed subspace of \( L_2(\mathbb{T} \times \mathbb{T}, \mu \times \mu) \) generated by \( \{ P(X)e_nh_n : X \in B(\mathbb{T}), n \in \mathbb{Z} \} \). The space \( K \) is stable under the action of the imprimitivity system \((R, P)\). Since the projection measure \( P \) acts only on the vector \( e_n \) and \( \{ \chi_Xe_n : X \in B(\mathbb{T}) \} \) generates \( L_2(\mathbb{T}, \mu) \), one has

\[
K \simeq L_2(\mathbb{T}, \mu) \otimes L,
\]

where \( L \) is the closed subspace generated by the vectors \( h_n, n \in \mathbb{Z} \).

According to \([5, \text{Proposition 1}]\), \( E \) is projection valued if and only if \( V(L_2(\mathbb{T}, \mu)) = K \), that is, \( L \) is one dimensional.

We summarize the above construction in form of a theorem.

**Theorem 1.** Any \( \mathbb{T} \)-covariant localization observable \( E : B(\mathbb{T}) \to L_2(\mathbb{T}, \mu) \) is of the form

\[
E(X) = \sum_{n,m \in \mathbb{Z}} \langle h_n | h_m \rangle \int_X z^{m-n} d\mu(z) |e_n\rangle \langle e_m|, \quad X \in B(\mathbb{T}),
\]

for some sequence of unit vectors \((h_n)_{n \in \mathbb{Z}}\) in \( L_2(\mathbb{T}, \mu) \). Two sequences of unit vectors \((h_n)_{n \in \mathbb{Z}}\) and \((k_n)_{n \in \mathbb{Z}}\) in \( L_2(\mathbb{T}, \mu) \) determine the same \( \mathbb{T} \)-covariant localization observable if and only if \( \langle h_n | h_m \rangle = \langle k_n | k_m \rangle \) for all \( n, m \in \mathbb{Z} \).

Two such operator measures \( E \) and \( E' \) are equivalent if and only if

\[
\langle h'_n | h'_m \rangle = \langle z_n h_n | z_m h_m \rangle,
\]

for some sequence \((z_n)_{n \in \mathbb{Z}}\) in \( \mathbb{T} \).

The operator measure \( E \) is projection valued exactly when the vectors \( h_n, n \in \mathbb{Z} \), are of the form \( h_n = z_n h \) for some unit vector \( h \) and phase factors \( z_n \in \mathbb{T} \).

**2.1. Commutative localizations.** By means of the above theorem, we are now in position to characterize the commutative \( \mathbb{T} \)-covariant localization observables. We recall that such an observable \( E \) is commutative if \( E(X)E(Y) = E(Y)E(X) \), for all \( X, Y \in B(\mathbb{T}) \), that is, if \( E \) is a commutative operator measure.

Let \((h_n)_{n \in \mathbb{Z}}\) be a sequence of unit vectors in \( L_2(\mathbb{T}, \mu) \), \( E \) the corresponding operator measure given by Theorem 1, and define, for all \( n, m \in \mathbb{Z} \),

\[
c_{n,m} = \langle h_n | h_m \rangle.
\]
Proposition 1. The $\mathbb{T}$-covariant localization observable $E$ is commutative if and only if

$$c_{n+k,m} = c_{n-m,k,m},$$

for all $n, m, k \in \mathbb{Z}$.

Proof. Define $\mu_{n,m}(X) := \langle n|[E(X)E(Y) - E(Y)E(X)]m \rangle$ for all $n, m \in \mathbb{Z}$ and $X, Y \in \mathcal{B}(\mathbb{T})$. Let $k \in \mathbb{Z}$, and calculate

$$\int_{\mathbb{T}} z^k d\mu_{n,m}(z) = [c_{n+k,m} - c_{n-m,k,m}] \int_{\mathbb{T}} z^{n+k-m} d\mu(z).$$

If $E(X)E(Y) = E(Y)E(X)$ for all $X, Y \in \mathcal{B}(\mathbb{T})$ then $\mu_{n,m}(X) = 0$ and, thus, $c_{n+k,m} = c_{n-m,k,m}$ for all $n, m, k \in \mathbb{Z}$.

Conversely, if $c_{n+k,m} = c_{n-m,k,m}$, holds then

$$\mu_{n,m}(X) = \sum_{k=-\infty}^{\infty} (c_{n+k,m} - c_{n-m,k,m}) \times \int_{\mathbb{T}} z^k d\mu(z) \int_{\mathbb{T}} z^{n+k-m} d\mu(z) = 0$$

for all $n, m \in \mathbb{Z}$ and $X, Y \in \mathcal{B}(\mathbb{T})$. Therefore, $E(X)E(Y) = E(Y)E(X)$ for all $X, Y \in \mathcal{B}(\mathbb{T})$. \hfill $\square$

An example of commutative $\mathbb{T}$-covariant localization observable is the following one. Let $\xi \in [-1, 1]$ and $\phi, \psi \in L^2(\mathbb{T}, \mu)$ two unit vectors such that

$$\langle \psi | \phi \rangle = \xi.$$

Consider the sequence of unit vectors $(h_n)_{n \in \mathbb{Z}}$, with

$$h_n = \psi, \text{ for even } n \text{ (including 0)},$$

$$h_n = \phi, \text{ for odd } n.$$

The coefficients $c_{n,m} = \langle h_n | h_m \rangle$, $n, m \in \mathbb{Z}$, satisfy condition (7) so that the corresponding $\mathbb{T}$-covariant localization observable $E^\xi$ is commutative. Notice that $E^\xi$ is projection valued if and only if $\xi = \pm 1$.

2.2. Matrix characterization. To end this section, we discuss an alternative characterization of the $\mathbb{T}$-covariant localization observables. If follows from Theorem 1 that the operator measure $E$ is uniquely defined in terms of the complex matrix elements $c_{n,m} = \langle h_n | h_m \rangle$, $n, m \in \mathbb{Z}$. It is clear that they satisfy the following two conditions:

(a) $c_{n,n} = 1$, for all $n \in \mathbb{Z}$,

(b) $\sum_{n,m=-\infty}^{k} c_{n,m} |e_n\rangle \langle e_m| \geq O$, for all $k \in \mathbb{N}$.
Conversely, it is known, see, for example, [9, Chpt. 3], that given a family of complex numbers \( \{c_{n,m} \in \mathbb{C} \mid n, m \in \mathbb{Z} \} \) which has the properties (a) and (b), there exists a sequence of unit vectors \((h_n)_{n \in \mathbb{Z}}\) such that \( c_{n,m} = \langle h_n | h_m \rangle \) and, hence, a \( \mathbb{T} \)-covariant localization observable \( E \) defined by

\[
E(X) = \sum_{n,m \in \mathbb{Z}} c_{n,m} \int_X z^{m-n} d\mu(z) |e_n \rangle \langle e_m|,
\]

for all \( X \in \mathcal{B}(\mathbb{T}) \).

For completeness, we give a simple construction of a sequence of unit vectors which generates the matrix. The construction is slightly more general than actually needed here.

Let \( J \subseteq \mathbb{Z} \) (especially \( J = \mathbb{Z} \) or \( J = \mathbb{N} \)). A matrix \((b_{n,m})_{n,m \in J}\) is positive semidefinite if for all sequences \((d_n)_{n \in J} \subset \mathbb{C} \), for which \( d_n \neq 0 \) for only finitely many \( n \in J \),

\[
\sum_{n,m \in J} \overline{d_n} b_{n,m} d_m \geq 0.
\]

For \( J = \mathbb{Z} \) this is equivalent to the above condition (b). (Condition (a) is equivalent to the fact that \( \|h_n\| = 1 \) for all \( n \in \mathbb{Z} \).

**Proposition 2.** Fix \( J \subseteq \mathbb{Z} \). Let \( \ell_2(J) \) be a sequence space with the basis \((\chi_{\{n\}})_{n \in J}\). A matrix \((b_{n,m})_{n,m \in J}\) is positive semidefinite if and only if there is a sequence \((h_n)_{n \in J}\) of vectors of \( \ell_2(J) \) such that \( b_{n,m} = \langle h_n | h_m \rangle \) for all \( n, m \in J \).

**Proof.** Consider a sequence \((h_n)_{n \in J}\) of vectors of \( \ell_2(J) \) and put \( b_{n,m} = \langle h_n | h_m \rangle \). If \((d_n)_{n \in J} \subset \mathbb{C} \) is a sequence for which \( d_n \neq 0 \) for only finitely many \( n \in J \), then

\[
\sum_{n,m \in J} \overline{d_n} b_{n,m} d_m = \left\langle \left( \sum_{n \in J} d_n h_n \right), \left( \sum_{m \in J} d_m h_m \right) \right\rangle \geq 0,
\]

the sums being finite.

Suppose then that \((b_{n,m})_{n,m \in J}\) is positive semidefinite. It follows that \( b_{n,n} \geq 0 \), \( b_{n,m} = \overline{b_{m,n}} \), and

\[
\left| \begin{array}{cc}
    b_{n,n} & b_{n,m} \\
    b_{m,n} & b_{m,m}
\end{array} \right| = b_{n,n} b_{m,m} - |b_{n,m}|^2 \geq 0
\]

for all \( n < m \). Especially, if \( b_{n,n} b_{m,m} = 0 \), then \( b_{n,m} = 0 \). Then the doubles series

\[
\sum_{n,m \in J, n \neq m \neq 0 \neq b_{n,m}} \frac{b_{n,m}}{\sqrt{b_{n,n} b_{m,m} (|n| + 1)(|m| + 1)}} |\chi_{\{n\}}\rangle \langle \chi_{\{m\}}|
\]
converges in the weak operator topology to a bounded and positive operator $S$. Let $A$ be its square root and, for all $n \in J$,

$$h_n := \sqrt{b_{n,n}(|n| + 1)} \chi_{\{n\}}.$$  

Then, taking into account that $S = A^2$, one gets, for all $n, m \in J$ such that $b_{n,n}b_{m,m} \neq 0$,

$$\langle h_n | h_m \rangle = \sqrt{b_{n,n}(|n| + 1)} \sqrt{b_{m,m}(|m| + 1)} \langle \chi_{\{n\}} | A^2 \chi_{\{m\}} \rangle = b_{n,m}.$$  

If $b_{n,n}b_{m,m} = 0$, for example $b_{n,n} = 0$, then $h_n = 0$ and, for all $m \in J$, $b_{n,m} = 0 = \langle h_n | h_m \rangle$. \hfill \Box

The above proposition, when applied together with the natural isomorphism $\ell^2(\mathbb{Z}) \ni \chi_{\{n\}} \mapsto e_n \in L_2(T, \mu)$, gives then a vector sequence representation of the matrix $(c_{n,m})_{n,m \in \mathbb{Z}}$ of a $T$-covariant localization observable $E$. In Section 4 we prove by direct methods a characterization of $T$-covariant localization observables in terms of the matrix $(c_{n,m})_{n,m \in \mathbb{Z}}$. The same result can also be obtained from a theorem of Holevo [7, Theorem 1], whose proof is also based on group theoretical arguments.

### 3. Covariant phase observables

Theorem 1 leads also to a characterization of the covariant phase observables. To describe them, let $\mathcal{H}$ be a complex separable Hilbert space, and let $(|n\rangle)_{n \in \mathbb{N}}$ be an orthonormal basis of $\mathcal{H}$. We call it the number basis. We define the number operator

$$N := \sum_{n \in \mathbb{N}} n |n\rangle \langle n|$$

with the domain $\mathcal{D}(N) := \{ \psi \in \mathcal{H} : \sum_{n \in \mathbb{N}} n^2 |\langle n| \psi \rangle|^2 < \infty \}$, and the unitary ‘phase shifter’ as

$$U^N(a) := \sum_{n \in \mathbb{N}} a^n |n\rangle \langle n|,$$

for all $a \in \mathbb{T}$. We say that a positive normalized operator measure $\tilde{E} : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(\mathcal{H})$ is a phase observable if it is covariant under the phase shifts, that is, if for any $X \in \mathcal{B}(\mathbb{T}), a \in \mathbb{T}$,

$$U^N(a) \tilde{E}(X) U^N(a)^* = \tilde{E}(aX).$$  

(9)

To determine all the phase observables, let $T : \mathcal{H} \to L_2(\mathbb{T}, \mu)$ be the linear isometry with the property

$$T |n\rangle = e_n,$$

for all $n \in \mathbb{N}$. 
Clearly, $T$ intertwines the unitary actions $U^N$ and $U$, $TU^N = UT$, and $X \mapsto T \tilde{E}(X)T^*$ is a $\mathbb{T}$-covariant localization observable acting in $L_2(\mathbb{T}, \mu)$. Using Theorem 1, and the fact that $T^*T = I$, one has the following result.

**Corollary 1.** A normalized positive operator measure $\tilde{E} : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(\mathcal{H})$ is a phase observable if and only if it is of the form

$$\tilde{E}(X) = T^* E(X)T, \ X \in \mathcal{B}(\mathbb{T}),$$

for some $\mathbb{T}$-covariant localization observable $E$.

Equivalently, $\tilde{E} : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(\mathcal{H})$ is a phase observable if and only if

$$\tilde{E}(X) = \sum_{n,m \in \mathbb{N}} \langle \xi_n | \xi_m \rangle \int_X z^{m-n} d\mu(z) |n\rangle\langle m|, \ X \in \mathcal{B}(\mathbb{T}),$$

for some sequence of unit vectors $(\xi_n)_{n \in \mathbb{N}}$ of $\mathcal{H}$. Two sequences of unit vectors $(\xi_n)_{n \in \mathbb{N}}$ and $(\eta_n)_{n \in \mathbb{N}}$ define the same phase observable exactly when $\langle \xi_n | \xi_m \rangle = \langle \eta_n | \eta_m \rangle$ for all $n, m \in \mathbb{N}$.

Two phase observables $\tilde{E}$ and $\tilde{E}'$ are equivalent (in the sense of covariance systems) if and only if any of their generating vector sequences $(\xi_n)$ and $(\xi'_n)$ are such that, for each $n, m \in \mathbb{N}$, $\langle \xi'_n | \xi'_m \rangle = \langle z_n \xi_n | z_m \xi_m \rangle$ for some $z_n, z_m \in \mathbb{T}$.

Since $T : \mathcal{H} \to L_2(\mathbb{T}, \mu)$ is not surjective, there is no projection valued phase observable.

We note, in addition, that Proposition 1, when applied to phase observables, gives Eq. (7) for all $n, m, k \in \mathbb{N}$ with $m \geq k$. For $n = m$ this gives $|c_{n,n+k}| = |c_{n-k,n}|$ for all $n \geq k$, which implies that $c_{n,m} = 0$ for all $n \neq m$ (for details, see [11]). This means that the only commutative phase observable is the trivial one

$$\mathcal{B}(\mathbb{T}) \ni X \mapsto \mu(X)I \in \mathcal{L}(\mathcal{H}).$$

Following [8] we say that a positive semidefinite complex matrix $(c_{n,m})_{n,m \in \mathbb{N}}$ is a phase matrix if $c_{n,n} = 1$, for all $n \in \mathbb{N}$. According to [8, Phase Theorem 2.2], any phase observable $\tilde{E} : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(\mathcal{H})$ is of the form

$$\tilde{E}(X) = \sum_{n,m \in \mathbb{N}} c_{n,m} \int_X z^{m-n} d\mu(z) |n\rangle\langle m|$$

for a unique phase matrix $(c_{n,m})$, and any phase matrix determines a phase observable in this way. The equivalence of the two characterizations of the phase observables is again a consequence of Proposition 2.
4. Covariant localizations in a box: a direct method

We determine next the covariant localizations by direct methods, using only basic analysis and measure theory. Actually, we determine all the normalized (not necessarily positive nor self-adjoint) operator measures which are translation covariant on the interval $[0, 2\pi)$. In the rest of this paper, we use the interval $[0, 2\pi)$ instead of $\mathbb{T}$ when it simplifies the calculations. Note that the Haar measure $\mu$ is the normalized Lebesgue measure on $\mathcal{B}([0, 2\pi))$, the Borel $\sigma$-algebra of $[0, 2\pi)$, transferred by the map $\theta \mapsto e^{i\theta}$.

Let, again, $\mathcal{H}$ be a complex separable Hilbert space, but choose now an orthonormal basis $(|n\rangle)_{n \in \mathbb{Z}} \subset \mathcal{H}$ labeled by the integers. Define the "extended number operator" as follows: $\hat{N} := \sum_{n \in \mathbb{Z}} n|n\rangle\langle n|$ with its domain $\mathcal{D}(\hat{N}) := \{\psi \in \mathcal{H} : \sum_{n \in \mathbb{Z}} n^2|n\rangle\langle n| < \infty\}$, and define the corresponding unitary shift operators as

$$R(\theta) := e^{i\theta \hat{N}} = \sum_{n \in \mathbb{Z}} e^{in\theta}|n\rangle\langle n|$$

for all $\theta \in \mathbb{R}$.

We say that $E : \mathcal{B}([0, 2\pi)) \to \mathcal{L}(\mathcal{H})$ is an operator measure if it is $\sigma$-additive with respect to the weak operator topology. If $E(X)^* = E(X)$, or $E(X) \geq O$, for all $X \in \mathcal{B}([0, 2\pi))$, we say that $E$ is self-adjoint, or positive. If $E([0, 2\pi)) = I$, we say that the operator measure $E$ is normalized. Finally, $E$ is covariant if $R(\theta)E(X)R(\theta)^* = E(X \oplus \theta)$ for all $X \in \mathcal{B}([0, 2\pi))$ and $\theta \in \mathbb{R}$, where the symbol $\oplus$ means addition modulo $2\pi$.

Before characterizing covariant normalized operator measures we prove the following lemma:

**Lemma 1.** Fix $q \in \mathbb{Z}$, and let $\nu_q : \mathcal{B}([0, 2\pi)) \to \mathbb{C}$ be a $\sigma$-additive set function such that $\nu_q(X \oplus \theta) = e^{i\theta} \nu_q(X)$ for all $X \in \mathcal{B}([0, 2\pi))$ and $\theta \in [0, 2\pi)$, and for which $\nu_q([0, 2\pi)) = \delta_{0,q}$. Then $\nu_q(X) = c_q(2\pi)^{-1} \int_X e^{i\theta} d\theta$ for all $X \in \mathcal{B}([0, 2\pi))$, where $c_q \in \mathbb{C}$ and $c_0 = 1$.

**Proof.** Fix $q \in \mathbb{Z}$, and let $k \in \mathbb{Z}^+$. Now

$$\delta_{0,q} = \nu_q([0, 2\pi)) = \nu_q \left( \bigcup_{l=0}^{k-1} \left[ l2\pi k^{-1}, (l + 1)2\pi k^{-1} \right) \right)$$

$$= \sum_{l=0}^{k-1} \nu_q \left( [0, 2\pi k^{-1}) + l2\pi k^{-1} \right) = \sum_{l=0}^{k-1} e^{i2\pi ql^{-1}} \nu_q [0, 2\pi k^{-1})$$

(10) $$= \begin{cases} k \nu_q [0, 2\pi k^{-1}), & \text{when } qk^{-1} \in \mathbb{Z}, \\ 0, & \text{when } qk^{-1} \notin \mathbb{Z}. \end{cases}$$
Suppose that $q \in \mathbb{Z}$ and $k \in \mathbb{Z}^+$ are such that $qk^{-1} \notin \mathbb{Z}$. Then $\int_0^{2\pi k^{-1}} e^{iq\theta} d\theta \neq 0$, and we can define

$$c_q(k) := \frac{\nu_q([0, 2\pi k^{-1}])}{(2\pi)^{-1} \int_0^{2\pi k^{-1}} e^{iq\theta} d\theta},$$

so that

$$\nu_q([0, 2\pi k^{-1}]) = c_q(k) \frac{1}{2\pi} \int_0^{2\pi k^{-1}} e^{iq\theta} d\theta = c_q(k) \frac{e^{iq2\pi k^{-1}} - 1}{iq2\pi}.$$

On the other hand, for all $r \in \mathbb{Z}^+$, $q(rk)^{-1} \notin \mathbb{Z}$, and

$$\nu_q([0, 2\pi k^{-1}]) = \nu_q \left( \bigcup_{l=0}^{r-1} \left[ l2\pi (rk)^{-1}, (l+1)2\pi (rk)^{-1} \right) \right) = \left[ \sum_{l=0}^{r-1} e^{i2\pi q(rk)^{-1}l} \right] \nu_q([0, 2\pi (rk)^{-1}])$$

$$= c_q(rk) e^{iq2\pi k^{-1}} - 1 = \frac{e^{iq2\pi k^{-1}} - 1}{iq2\pi}.$$

This shows that $c_q(k) = c_q(rk)$, $r \in \mathbb{Z}^+$. Since $q(|q| + 1)^{-1} \notin \mathbb{Z}$, one has $c_q(k) = c_q((|q| + 1)k) = c_q(|q| + 1)$. Thus, for all $k \in \mathbb{Z}^+$, for which $qk^{-1} \notin \mathbb{Z}$, the number $c_q(k)$ is the same, and we may define $c_q := c_q(|q| + 1)$ for all $q \in \mathbb{Z}$ and $q \neq 0$.

If $qk^{-1} \in \mathbb{Z}$, $q \in \mathbb{Z}$, $k \in \mathbb{Z}^+$, equation (10) gives

$$\nu_q([0, 2\pi k^{-1}]) = \frac{\delta_{0,q} k}{k} = \frac{1}{2\pi} \int_0^{2\pi k^{-1}} e^{iq\theta} d\theta.$$

Thus, if we define $c_0 := 1$ we get

$$\nu_q([0, 2\pi k^{-1}]) = c_q \frac{1}{2\pi} \int_0^{2\pi k^{-1}} e^{iq\theta} d\theta,$$

for all $k \in \mathbb{Z}^+$ and $q \in \mathbb{Z}$.

Let $q \in \mathbb{Z}$. Now one gets

$$\nu_q \left( \bigcup_{p=1}^{\infty} \{ p^{-1} \} \right) = \nu_q(\{0\}) \sum_{p=1}^{\infty} e^{iqp^{-1}},$$

which implies that $\nu_q(\{0\}) = 0$. Thus the measure $\nu_q$ is non-atomic, that is, $\nu_q(\{x\}) = e^{iqx} \nu_q(\{0\}) = 0$, $x \in [0, 2\pi)$, which implies that its distribution function $x \mapsto \nu_q([0, x])$ is continuous. From Equation (12)
it follows that for all \( k \in \mathbb{Z}^+, \ p \in \{1, 2, \ldots, k\}, \)
\[
\nu_q([0, 2\pi pk^{-1}]) = \nu_q \left( \bigcup_{l=0}^{p-1} \left[ l2\pi k^{-1}, (l + 1)2\pi k^{-1} \right] \right) 
= c_q \frac{1}{2\pi} \int_0^{2\pi pk^{-1}} e^{iq\theta} \, d\theta. \tag{13}
\]
Since \( x \mapsto \nu_q([0, x]) \) is continuous, and the set \( \{ 2\pi pk^{-1} \in [0, 2\pi) \mid k \in \mathbb{Z}^+, \ p \in \{1, 2, \ldots, k\} \} \) is dense in \( [0, 2\pi) \), it follows that for all \( x \in (0, 2\pi) \)
\[
\nu_q([0, x]) = c_q \frac{1}{2\pi} \int_0^x e^{iq\theta} \, d\theta. \tag{14}
\]
By the Hahn extension theorem
\[
\nu_q(X) = c_q \frac{1}{2\pi} \int_X e^{iq\theta} \, d\theta \quad \text{for all } X \in \mathcal{B}([0, 2\pi)) \text{ and } q \in \mathbb{Z}. \quad \Box
\]

**Theorem 2.** Let \( E : \mathcal{B}([0, 2\pi)) \rightarrow \mathcal{L}(\mathcal{H}) \) be a covariant normalized operator measure. For any \( X \in \mathcal{B}([0, 2\pi)) \),
\[
E(X) = \sum_{n,m \in \mathbb{Z}} c_{n,m} \frac{1}{2\pi} \int_X e^{i(n-m)\theta} \, d\theta |n\rangle \langle m|, \tag{15}
\]
where \( c_{n,m} \in \mathbb{C} \) and \( c_{n,n} = 1 \) for all \( n, m \in \mathbb{Z} \). If \( E \) is self-adjoint, then \( \bar{c}_{n,m} = c_{m,n} \) for all \( n, m \in \mathbb{Z} \), and if \( E \) is positive, then
\[
\sum_{n,m=-k}^{k} c_{n,m} |n\rangle \langle m| \geq O, \tag{16}
\]
for all \( k \in \mathbb{N} \).

**Proof.** Denoting, in Lemma (1), \( q = n - m \) and \( \nu_q(X) = \langle n|E(X)|m\rangle \)
Equation (15) follows. If \( E \) is self-adjoint, then from (15), one gets
\[
\bar{c}_{n,m} = 2\pi \lim_{\epsilon \to 0^+} \frac{\langle n|E([0, \epsilon])|m\rangle}{\epsilon} = c_{m,n}
\]
for all \( n, m \in \mathbb{Z} \).

Suppose that \( E \) is positive and, thus, self-adjoint. Hence, if (16) does not hold, one may choose a \( \varphi \in \mathcal{H} \) and an \( l \in \mathbb{N} \) such that
\[
\sum_{n,m=-l}^{l} c_{n,m} \langle \varphi|n\rangle \langle m|\varphi\rangle < 0,
\]
and define a function
\[
g : [0, 2\pi) \rightarrow \mathbb{R}, \ \theta \mapsto g(\theta) := \sum_{n,m=-l}^{l} c_{n,m} e^{i(n-m)\theta} \langle \varphi|n\rangle \langle m|\varphi\rangle.
\]
Due to the continuity of \( g \) one can choose an \( \epsilon \in (0, 2\pi) \) such that 
\[
\int_0^\epsilon g(\theta) d\theta < 0.
\]
Thus, denoting 
\[
I_\epsilon := \sum_{n=-l}^l \langle n \rangle |n\rangle,
\]

\[
\langle I_\epsilon \varphi | E([0,\epsilon]) I_\epsilon \varphi \rangle = \frac{1}{2\pi} \int_0^\epsilon g(\theta) d\theta < 0,
\]

which contradicts the positivity of \( E \).

For later use we note that the positive semi-definiteness condition (16) of the matrix \((c_{n,m})_{n,m \in \mathbb{Z}}\) can be written equivalently as the following determinant condition, see, e.g. [9, Chpt 3.1]:

\[
\begin{vmatrix}
  c_{k_1,k_1} & c_{k_1,k_2} & \cdots & c_{k_1,k_s} \\
  c_{k_2,k_1} & c_{k_2,k_2} & \cdots & c_{k_2,k_s} \\
  \vdots & \vdots & \ddots & \vdots \\
  c_{k_s,k_1} & c_{k_s,k_2} & \cdots & c_{k_s,k_s}
\end{vmatrix} \geq 0
\]

(17)

for all \( s \in \mathbb{Z}^+, \{k_1, k_2, \ldots, k_s\} \subset \mathbb{Z}, \) and \( k_1 < k_2 < \ldots < k_s \). Note that in this case \( c_{n,m} = \overline{c_{m,n}} \) and \( |c_{n,m}| \leq 1 \) for all \( n, m \in \mathbb{Z} \).

**Remark 1.** One may ask if the converse statement of Theorem 2 is also true. Let \((c_{n,m})_{n,m \in \mathbb{Z}}\) be an infinite-dimensional complex matrix, and suppose that \( c_{n,n} = 1 \) for all \( n \in \mathbb{Z} \). Let \( M := \text{lin}\{|n\rangle| n \in \mathbb{Z}\} \), and define the following function for all \( \varphi, \psi \in M \):

\[
R \ni \theta \mapsto C_{\varphi,\psi}(\theta) := \sum_{n,m=-\infty}^\infty c_{n,m}e^{i(n-m)\theta} \langle \varphi | n \rangle \langle m | \psi \rangle \in \mathbb{C}.
\]

For \( \varphi, \psi \in M \), define

\[
E_{\varphi,\psi}([0,2\pi]) := \frac{1}{2\pi} \int_0^{2\pi} C_{\varphi,\psi}(\theta) d\theta = \langle \varphi | \psi \rangle.
\]

Clearly, \( E_{\varphi,\psi}([0,2\pi]) = \langle \varphi | \psi \rangle \), and \( (\varphi, \psi) \mapsto E_{\varphi,\psi}([0,2\pi]) \) is a bounded sesquilinear form defined on the dense subspace \( M \) of \( \mathcal{H} \). Hence the mapping \( (\varphi, \psi) \mapsto E_{\varphi,\psi}([0,2\pi]) \) has a unique bounded extension to \( \mathcal{H} \) which is \( (\varphi, \psi) \mapsto \langle \varphi | \psi \rangle \). We let \( E([0,2\pi]) \) denote the unique bounded operator, which, actually, is the identity operator \( I \).

Consider the following sesquilinear form defined for all \( X \in B([0,2\pi]) \):

\[
\mathcal{M} \times \mathcal{M} \ni (\varphi, \psi) \mapsto E_{\varphi,\psi}(X) := \frac{1}{2\pi} \int_X C_{\varphi,\psi}(\theta) d\theta \in \mathbb{C}.
\]

This form need not be bounded, so that it does not necessarily define a bounded operator on \( \mathcal{H} \). Thus, the formal notation

\[
E(X) = \sum_{n,m \in \mathbb{Z}} c_{n,m} \frac{1}{2\pi} \int_X e^{i(n-m)\theta} d\theta |n\rangle \langle m|, \quad X \in B([0,2\pi]),
\]

(18)
must be understood as the sesquilinear form \((\varphi, \psi) \mapsto E_{\varphi, \psi}(X)\) defined on \(\mathcal{M}\).

Since \(R(\theta)\mathcal{M} = \mathcal{M}\), it follows that \(X \mapsto E(X)\) is covariant in the sense that

\[
E_{R(\theta)^*\varphi, R(\theta)^*\psi}(X) = E_{\varphi, \psi}(X \oplus \theta)
\]

for all \(\varphi, \psi \in \mathcal{M}\), \(\theta \in [0, 2\pi)\), and \(X \in \mathcal{B}([0, 2\pi))\).

Finally, if \(E_{\varphi, \varphi}(X) \geq 0\) for all \(X \in \mathcal{B}([0, 2\pi))\) and \(\varphi \in \mathcal{M}\) we say that \(E\) is positive. If \(E\) is positive then the matrix \((c_{n,m})_{n,m \in \mathbb{Z}}\) is positive semidefinite (see the proof of Theorem 2). Hence, \(0 \leq E_{\varphi, \varphi}(X) \leq E_{\varphi, \varphi}([0, 2\pi)) = \|\varphi\|^2\), \(\varphi \in \mathcal{M}\), \(X \in \mathcal{B}([0, 2\pi))\), and \((\varphi, \psi) \mapsto E_{\varphi, \psi}(X)\) is bounded on \(\mathcal{M}\). In this case, the sesquilinear form \(E(X)\), for all \(X \in \mathcal{B}([0, 2\pi))\), can be regarded as a bounded operator with the unique matrix elements \(E_{[n],[m]}(X) = c_{n,m}(2\pi)^{-1} \int_X e^{i(n-m)\theta} d\theta\), \(n, m \in \mathbb{Z}\). The mapping \(E : \mathcal{B}([0, 2\pi)) \to \mathcal{L}(\mathcal{H})\) is \(\sigma\)-additive (see the proof of Phase Theorem 2.2 of [8]). Thus, Equation (18) defines weakly a covariant normalized positive operator measure \(X \mapsto E(X)\).

### 4.1. Projection valued covariant normalized positive operator measures

The application of [5, Proposition 1] in Section 2 gave, in Theorem 1, also a characterization of the \(\mathcal{T}\)-covariant projection measures. In the present approach one has to determine separately which of the solutions of Theorem 2 are projection valued. We shall do that next.

**Proposition 3.** Let \(E : \mathcal{B}([0, 2\pi)) \to \mathcal{L}(\mathcal{H})\) be a covariant normalized positive operator measure with the associated structure matrix \((c_{n,m})_{n,m \in \mathbb{Z}}\). \(E\) is projection valued, that is, \(E(X)^2 = E(X)\) for all \(X \in \mathcal{B}([0, 2\pi))\), if and only if \(|c_{n,m}| = 1\) for all \(n, m \in \mathbb{Z}\).

**Proof.** Let \(x \in (0, 1)\) and \(n \in \mathbb{Z}\). Using the equations \(\sum_{k=1}^{\infty} k^{-2} = \pi^2/6\) and \(y^2 = \pi^2/3 + 4 \sum_{k=1}^{\infty} k^{-2} \cos(k(y + \pi))\), \(y \in (-\pi, \pi)\), one gets

\[
\langle n \mid E([0, 2\pi x])^2 \mid n \rangle = \sum_{s=-\infty}^{\infty} |c_{n,s}|^2 \left| \frac{1}{2\pi} \int_0^{2\pi x} e^{i(s-n)\theta} d\theta \right|^2
\]

\[
\leq x^2 + \frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{|e^{2\pi ikx} - 1|^2}{k^2}
\]

\[
= x^2 + \frac{1}{\pi^2} \sum_{k=1}^{\infty} \frac{1}{k^2} - \frac{1}{\pi^2} \sum_{k=1}^{\infty} \frac{\cos(2\pi xk)}{k^2}
\]

\[
= x = \langle n \mid E([0, 2\pi x]) \mid n \rangle
\]

where the equality sign holds only when \(|c_{n,m}| = 1\) for all \(n, m \in \mathbb{Z}\).
On the other hand, if $|c_{n,m}| = 1$, then $c_{n,m} = e^{i(v_n - v_m)}$, $v_n \in [0, 2\pi)$, for all $n, m \in \mathbb{Z}$, since $(c_{n,m})_{n,m \in \mathbb{Z}}$ is the structure matrix of $E$ [10]. Define the following unitary transformations: $W : \mathcal{H} \to \mathcal{H}, |n\rangle \mapsto e^{-i\nu_n} |n\rangle$ and $T : \mathcal{H} \to L^2[0, 2\pi), |n\rangle \mapsto f_n$, where $f_n(x) = 1/\sqrt{2\pi} e^{-inx}$, $x \in [0, 2\pi)$. Now $E$ is unitarily equivalent to the canonical spectral measure $E^Q$, $E^Q(X)f = \chi_X f$, $X \in \mathcal{B}([0, 2\pi))$, $f \in L^2[0, 2\pi)$, that is, $E(X) = W^* T^* E^Q(X)TW$, and, thus, $E$ is projection valued. \hfill \Box

Remark 2. The $\mathbb{T}$-covariant localization observables $E : \mathcal{B}(\mathbb{T}) \to \mathcal{L}(\mathcal{H})$ are compactly supported, supp $E = \mathbb{T}$. Therefore, all their moment operators

$$V^{(k)} = \int_{\mathbb{T}} z^k dE(z),$$

$$E^{(k)} = \int_{\mathbb{T}} \text{arg}(z)^k dE(z),$$

with $k \in \mathbb{Z}$, are bounded operators. The cyclic moments $V^{(k)}$ are contractions whereas the phase moments $E^{(k)}$ are self-adjoint. The operator measure $E$ is uniquely determined by both of its moment operator sequences $(V^{(k)})_{k \in \mathbb{Z}}$ and $(E^{(k)})_{k \in \mathbb{Z}}$.

The operator measure $E$ is projection valued if and only if all its cyclic moment operators $V^{(k)}$, $k \in \mathbb{Z}$, are unitary. If $E$ is not projection valued then, at least, some of the moment operators $V^{(k)}$ are non-unitary. However, if the first cyclic moment operator $V^{(1)}$ of $E$ is unitary, then $E$ is projection measure. Indeed,

$$V^{(1)} = \sum_{n \in \mathbb{Z}} c_{n,n+1} |n\rangle \langle n+1|,$$

so that $V^{(1)}(V^{(1)})^* = I$ implies that $|c_{n,n+1}| = 1$ for all $n \in \mathbb{Z}$. By induction, using (17), one then quickly computes that $|c_{n,n+k}| = 1$ for all $n \in \mathbb{Z}$ and $k \in \mathbb{Z}^+$, which confirms that $E$ is projection measure (and hence all $V^{(k)}$ are unitary).

We recall further that $E^{(2)} = (E^{(1)})^2$ exactly when $E$ is projection valued [12, Appendix, Sect. 3]. In view of that, it is interesting to observe that, due to the covariance condition, the operator measure $E$ (projection valued or not) is uniquely determined already by its first phase moment operator

$$E^{(1)} = \int_{\mathbb{T}} \text{arg}(z) dE(z) = \int_0^{2\pi} \theta dE(\theta)$$

$$= \pi I + \sum_{n \neq m = -\infty}^{\infty} \frac{c_{n,m}}{i(n-m)} |n\rangle \langle m|$$
since \(c_{n,m} = i(n - m)\langle n|E^{(1)}|m\rangle\) for all \(n \neq m\). Clearly, the spectral measure \(E^{(1)}\) of the bounded self-adjoint operator \(E^{(1)}\) is shift covariant if and only if it is unitarily equivalent to \(E^Q\).

References
