Abstract

The vanishing of the cosmological constant and the non-renormalization theorem are verified at two loops by explicit computation using the hyperelliptic language and the newly obtained chiral measure of D’Hoker and Phong. A set of identities is found which is used in the verification of the non-renormalization theorem and leads to a great simplification of the calculation of the four-particle amplitude at two loops.

1 Introduction

Although we believe that superstring theory is finite in perturbation at any order [1, 2, 3, 4], a rigorous proof is still lacking despite great advances in the covariant formulation of superstring perturbation theory á la Polyakov. In particular, there is a non-renormalization theorem [4]. In spite of the efforts of many authors, it is very difficult to verify this theorem explicitly. Even in the case of the cosmological constant, i.e. the vacuum amplitude, this problem has not been completely solved. At two loops these problems were solved explicitly by using the hyperelliptic formalism in a series of papers [5, 6, 7, 8, 9]. The explicit result was also used by Iengo [10] to prove the vanishing of perturbative correction to the $R^4$ term [11] at two loops, in agreement with the indirect argument of Green and Gutperle [12], Green, Gutperle and Vanhove [13], and Green and Sethi [14] that the $R^4$ term does not receive perturbative contributions beyond one loop. In the general case, there is no satisfactory solution. For a review of these problem we refer the reader to [15, 16].

Recently two-loop superstring was studied by D’Hoker and Phong. In a series of papers [17, 18, 19, 20] (for a recent review see [16]), D’Hoker and Phong found an unambiguous and slice-independent two-loop superstring measure on moduli space for even spin structure from first principles.

Although their result is quite explicit, it is still a difficult problem to use it in actual computation. In [20], D’Hoker and Phong used their result to compute explicitly the chiral measure by choosing the split gauge and proved the vanishing of the cosmological constant and the non-renormalization theorem [21, 4]. They also computed the four-particle amplitude in another forthcoming paper [22]. Although the final results are exactly the expected, their computation is quite difficult to follow because of the use of theta functions. Also modular invariance is absurd in their computations because of
the complicated dependence between the 2 insertion points (the insertion points are also spin structure dependent).

Although the vanishing of the cosmological constant and the non-renormalization theorem was proved explicitly in previous works [5, 6, 7], it would be interesting to study this problem again by using the newly obtained result of D’Hoker and Phong. The main purpose of this study is as a warm up exercise for the computation of the possibly non-vanishing four-particle amplitude. As we will see in this paper, some expressions are non-vanishing after summation over spin structures. Nevertheless the combination of the symmetry of the computed expression and the relevant kinematic factor gives a vanishing result. In a previous paper [23], we report the main results of our computation of two loop superstring theory by using hyperelliptic language. In this paper we will present the details for the proof of the vanishing of the cosmological constant and the non-renormalization theorem. The computation of the non-vanishing four-particle amplitude is given in another publication [24].

The organization of this paper is as follows. In the next section we will recall the relevant results of hyperelliptic representation of the genus 2 Riemann surface and set our notations for all the correlators. In section 3 we recall the results of D’Hoker and Phong for the chiral measure. In section 4 we computed explicitly all the relevant quantities in the chiral measure. Here we mainly concentrated on the spin structure dependent parts. In section 5 we established a set of identities and proved the vanishing of the cosmological constant. The identities will also be used in the next section in the verification of the non-renormalization theorem. Here modular invariance is maintained explicitly. In this section we also discuss the importance of taking the limit $\tilde{p}_1 \rightarrow q_{1,2}$ and mention the (six) Riemann identities which are not fully modular invariant. In section 6 we proved the non-renormalization theorem. In particular we study carefully the most difficult part of the three-particle amplitude. Here the symmetry of the relevant kinematic factor is very important in the proof of the non-renormalization theorem. The (point-wise) vanishing of all the 1-, 2- and 3-particle amplitude leads a great simplification of the computation of the 4-particle amplitude [24].

Here we note again that D’Hoker and Phong have proved that the cosmological constant and the 1-, 2- and 3-point functions are zero point-wise in moduli space [21]. They have also computed the 4-particle amplitude [22]. The agreement of the results from these two different gauge choices and two different methods of computations is another proof of the validity of the new
supersymmetric gauge fixing method at two loops.

2 Genus 2 hyperelliptic Riemann surface

First we remind that a genus-\(g\) Riemann surface, which is the appropriate world sheet for one and two loops, can be described in full generality by means of the hyperelliptic formalism. This is based on a representation of the surface as two sheet covering of the complex plane described by the equation:

\[ y^2(z) = \prod_{i=1}^{2g+2} (z - a_i), \]

(1)

The complex numbers \(a_i, (i = 1, \cdots, 2g + 2)\) are the \(2g + 2\) branch points, by going around them one passes from one sheet to the other. For two-loop \((g = 2)\) three of them represent the moduli of the genus 2 Riemann surface over which the integration is performed, while the other three can be arbitrarily fixed. Another parametrization of the moduli space is given by the period matrix.

At genus 2, by choosing a canonical homology basis of cycles we have the following list of 10 even spin structures:

\[
\begin{align*}
\delta_1 & \sim \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \sim (a_1a_2a_3|a_4a_5a_6), & \delta_2 & \sim \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \sim (a_1a_2a_4|a_3a_5a_6), \\
\delta_3 & \sim \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \sim (a_1a_2a_5|a_3a_4a_6), & \delta_4 & \sim \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \sim (a_1a_2a_6|a_3a_4a_5), \\
\delta_5 & \sim \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \sim (a_1a_3a_4|a_2a_5a_6), & \delta_6 & \sim \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \sim (a_1a_3a_5|a_2a_4a_6), \\
\delta_7 & \sim \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \sim (a_1a_3a_6|a_2a_4a_5), & \delta_8 & \sim \begin{bmatrix} 0 & 0 \\ 1 & 1 \end{bmatrix} \sim (a_1a_4a_5|a_2a_3a_6), \\
\delta_9 & \sim \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \sim (a_1a_4a_6|a_2a_3a_5), & \delta_{10} & \sim \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \sim (a_1a_5a_6|a_2a_3a_4).
\end{align*}
\]

We will denote an even spin structure as \((A_1A_2A_3|B_1B_2B_3)\). By convention \(A_1 = a_1\). For each even spin structure we have a spin structure dependent factor from determinants which is given as follows [5]:

\[
Q_\delta = \prod_{i<j}(A_i - A_j)(B_i - B_j).
\]

(2)
This is a degree 6 homogeneous polynomials in $a_i$.

At two loops there are two odd supermoduli and this gives two insertions of supercurrent at two different points $x_1$ and $x_2$. Previously the chiral measure was derived in [25, 15] by a simple projection from the supermoduli space to the even moduli space. This projection does’t preserve supersymmetry and there is a residual dependence on the two insertion points. This formalism was used in [5, 6, 7, 8]. In these papers we found that it is quite convenient to choose these two insertion points as the two zeros of a holomorphic abelian differential which are moduli independent points on the Riemann surface. In hyperelliptic language these two points are the same points on the upper and lower sheet of the surface. We denote these two points as $x_1 = x_+$ (on the upper sheet) and $x_2 = x_-$ (on the lower sheet). We made these convenient choices again in [23] and will make the same choices in this paper and [24].

In the following we will give some formulas in hyperelliptic representation which will be used later. First all the relevant correlators are given by

\begin{align*}
\langle \psi^{\mu}(z)\psi^{\nu}(w) \rangle &= -\delta^{\mu\nu} G_{1/2}[\delta](z, w) = -\delta^{\mu\nu} S_\delta(z, w), \\
\langle \partial_z X^{\mu}(z)\partial_w X^{\nu}(w) \rangle &= -\delta^{\mu\nu} \partial_z \partial_w \ln E(z, w), \\
\langle b(z)c(w) \rangle &= +G_2(z, w), \\
\langle \beta(z)\gamma(w) \rangle &= -G_{3/2}[\delta](z, w),
\end{align*}

where

\begin{align*}
S_\delta(z, w) &= \frac{1}{z-w} \frac{u(z) + u(w)}{2\sqrt{u(z)u(w)}}, \\
u(z) &= \prod_{i=1}^{3} \left( \frac{z-A_i}{z-B_i} \right)^{1/2}, \\
G_2(z, w) &= -H(w, z) + \sum_{a=1}^{3} H(w, p_1) \varpi_a(z, z), \\
H(w, z) &= \frac{1}{2(w-z)} \left( 1 + \frac{y(w)}{y(z)} \right) \frac{y(w)}{y(z)}, \\
G_{3/2}[\delta](z, w) &= -P(w, z) + P(w, q_1)\psi_1^*(z) + P(w, q_2)\psi_2^*(z), \\
P(w, z) &= \frac{1}{\Omega(w) S_\delta(w, z) \Omega(z)}.
\end{align*}

\[\text{We follow closely the notation of [18].}\]
where $\Omega(z)$ is an abelian differential satisfying $\Omega(q_{1,2}) \neq 0$ and otherwise arbitrary. These correlators were adapted from [26]. $\omega_a(z, w)$ are defined in [17] and $\psi^*_a(z)$ are the two holomorphic $\frac{3}{2}$-differentials. When no confusion is possible, the dependence on the spin structure $[\delta]$ will not be exhibited.

In order to take the limit of $x_{1,2} \to q_{1,2}$ we need the following expansions:

$$G_{3/2}(x_2, x_1) = \frac{1}{x_1 - q_1} \psi_1^*(x_2) - \psi_1^*(x_2) f_{3/2}^{(1)}(x_2) + O(x_1 - q_1),$$

$$G_{3/2}(x_1, x_2) = \frac{1}{x_2 - q_2} \psi_2^*(x_1) - \psi_2^*(x_1) f_{3/2}^{(2)}(x_1) + O(x_2 - q_2),$$

for $x_{1,2} \to q_{1,2}$. By using the explicit expression of $G_{3/2}$ in (11) we have

$$f_{3/2}^{(1)}(q_2) = -\frac{\partial_{q_2} S(q_1, q_2)}{S(q_1, q_2)} + \partial \psi_2^*(q_2),$$

$$f_{3/2}^{(2)}(q_1) = \frac{\partial_{q_2} S(q_2, q_1)}{S(q_1, q_2)} + \partial \psi_1^*(q_1) = f_{3/2}^{(1)}(q_2)\big|_{q_1 \to q_2}.$$  

The quantity $\psi^*_a(z)$'s are holomorphic $\frac{3}{2}$-differentials and are constructed as follows:

$$\psi^*_a(z) = (z - q_a) S(z, q_a) \frac{y(q_a)}{y(z)}, \quad a = 1, 2.$$  

For $z = q_1, 2$ we have

$$\psi^*_a(q_b) = \delta_{a,b},$$

$$\partial \psi_1^*(q_1) = -\partial \psi_2^*(q_1) = S(q_1, q_2) = \frac{i}{4} S_1(q),$$

$$\partial \psi_1^*(q_1) = \partial \psi_2^*(q_2) = -\frac{1}{2} \Delta_1(q),$$

$$\partial^2 \psi_1^*(q_1) = \partial^2 \psi_2^*(q_2) = \frac{1}{16} S_1^2(q) + \frac{1}{4} \Delta_1^2(q) + \frac{1}{2} \Delta_2(q),$$

where

$$\Delta_n(x) \equiv \sum_{i=1}^{6} \frac{1}{(x - a_i)^n},$$

$$S_n(x) \equiv \sum_{i=1}^{3} \left[ \frac{1}{(x - A_i)^n} - \frac{1}{(x - B_i)^n} \right],$$

for $n = 1, 2$. This shows that $\partial \psi^*_a(q_{a+1})$ and $\partial^2 \psi^*_a(q_a)$ are spin structure dependent.
3 The chiral measure: the result of D’Hoker and Phong

The chiral measure obtained in [17, 18, 19, 20] after making the choice \( x_\alpha = q_\alpha \ (\alpha = 1, 2) \) is

\[
\mathcal{A}[\delta] = i \mathcal{Z} \left\{ 1 + \mathcal{X}_1 + \mathcal{X}_2 + \mathcal{X}_3 + \mathcal{X}_4 + \mathcal{X}_5 + \mathcal{X}_6 \right\},
\]

\[
\mathcal{Z} = \frac{(\Pi_a b(p_a) \Pi_a \delta(\beta(q_\alpha)))}{\det \omega_f \omega_f(p_a)}, \tag{24}
\]

and the \( \mathcal{X}_i \) are given by:

\[
\mathcal{X}_1 + \mathcal{X}_6 = \frac{\zeta_1 \zeta_2}{16\pi^2} \left[ -\langle \psi(q_1) \cdot \partial X(q_1) \psi(q_2) \cdot \partial X(q_2) \rangle - \partial_{q_1} G_2(q_1, q_2) \partial \psi_1^*(q_2) + \partial_{q_2} G_2(q_2, q_1) \partial \psi_2^*(q_1) + 2G_2(q_1, q_2) \partial \psi_1^*(q_2) f_3^{(1)}(q_2) - 2G_2(q_2, q_1) \partial \psi_2^*(q_1) f_3^{(2)}(q_1) \right], \tag{25}
\]

\[
\mathcal{X}_2 + \mathcal{X}_3 = \frac{\zeta_1 \zeta_2}{8\pi^2} S_8(q_1, q_2)
\]

\[
\times \sum_{a=1}^3 \bar{\varpi}_a(q_1, q_2) \left[ \langle T(\tilde{p}_a) \rangle + \tilde{B}_2(\tilde{p}_a) + \tilde{B}_3(\tilde{p}_a) \right], \tag{26}
\]

\[
\mathcal{X}_4 = \frac{\zeta_1 \zeta_2}{8\pi^2} S_8(q_1, q_2) \sum_{a=1}^3 \left[ \partial_{p_a} \partial_{q_1} \ln E(p_a, q_1) \varpi_a^*(q_2) + \partial_{p_a} \partial_{q_2} \ln E(p_a, q_2) \varpi_a^*(q_1) \right], \tag{27}
\]

\[
\mathcal{X}_5 = \frac{\zeta_1 \zeta_2}{16\pi^2} \sum_{a=1}^3 \left[ S_8(p_a, q_1) \partial_{p_a} S_8(p_a, q_2) - S_8(p_a, q_2) \partial_{p_a} S_8(p_a, q_1) \right] \varpi_a(q_1, q_2). \tag{28}
\]

Furthermore, \( \tilde{B}_2 \) and \( \tilde{B}_{3/2} \) are given by

\[
\tilde{B}_2(w) = -2 \sum_{a=1}^3 \partial_{p_a} \partial_w \ln E(p_a, w) \varpi_a^*(w), \tag{29}
\]

\[
\tilde{B}_{3/2}(w) = \sum_{a=1}^2 \left( G_2(w, q_a) \partial_{q_a} \psi^*_a(q_a) + \frac{3}{2} \partial_{q_a} G_2(w, q_a) \psi^*_a(q_a) \right). \tag{30}
\]
In comparing with [19] we have written $\mathcal{X}_2$, $\mathcal{X}_3$ together and we didn’t split $T(w)$ into different contributions. We also note that in eq. (26) the three arbitrary points $\tilde{p}_a$ ($a = 1, 2, 3$) can be different from the three insertion points $p_a$’s of the $b$ ghost field. The symbol $\tilde{\varpi}_a$ is obtained from $\varpi_a$ by changing $p_a$’s to $\tilde{p}_a$’s. In the following computation we will take the limit of $\tilde{p}_1 \to q_1$. In this limit we have $\tilde{\varpi}_{2,3}(q_1, q_2) = 0$ and $\tilde{\varpi}_1(q_1, q_2) = -1$. This choice greatly simplifies the formulas and also make the summation over spin structure doable (see below and [23, 24]).

4 The chiral measure in hyperelliptic language

The strategy we will follow is to isolate all the spin structure dependent parts first. As we will show in the following the spin structure dependent factors are just $S(q_1, q_2)$, $\partial_{q_1}S(q_1, q_2)$ and the Szegő kernel if we also include the vertex operators. Before we do this we will first write the chiral measure in hyperelliptic language and take the limit of $\tilde{p}_1 \to q_1$.

Let’s start with $X_5$. We have

$$S(z, q_1)\partial_z S(z, q_2) - S(z, q_2)\partial_z S(z, q_1) = \frac{i}{4(z - q)^2}S_1(z),$$

(31)

So the spin structure dependent factor from $\mathcal{X}_5$ is effectively $S(z+, z-)$ as shown by the following formulas:

$$S(q_1, q_2) = -S(q_2, q_1) = \frac{i}{4}S_1(q),$$

(32)

$$\partial_{q_2}S(q_1, q_2) = -\partial_{q_1}S(q_2, q_1) = -\frac{i}{8}S_2(q).$$

(33)

For $\mathcal{X}_4$, the spin structure dependent factor is simply $S_1(q) \propto S(q_1, q_2)$ as $\ln E(p_a, q_b)$ and $\varpi^*_a(q_b)$ are spin structure independent (their explicit expressions are not needed in this paper and will be given in [24]).

For $\mathcal{X}_2 + \mathcal{X}_3$, we first compute the various contributions from the different fields. The total stress energy tensor is:

$$T(z) = \frac{1}{2} : \partial_z X(z) \cdot \partial_z X(z) : + \frac{1}{2} : \psi(z) \cdot \partial_z \psi(z) :$$

$$- : (\partial bc + 2b\partial c + \frac{1}{2}\partial \beta \gamma + \frac{3}{2}\beta \partial \gamma)(z) :$$

$$\equiv T_X(z) + T_\psi(z) + T_{bc}(z) + T_{\beta \gamma}(z),$$

(34)
in an obvious notations. The various contributions are

\begin{align*}
T_X(w) &= -10T_1(w), \\
T_\psi(w) &= 5\tilde{g}_{1/2}(w) = \frac{5}{32} (S_1(w))^2, \\
T_{bc}(w) &= \tilde{g}_2(w) - 2\partial_w f_2(w), \\
T_{\beta\gamma}(w) &= -\tilde{g}_{3/2}(w) + \frac{3}{2} \partial_w f_{3/2}(w),
\end{align*}

where

\begin{align*}
f_2(w) &= -\frac{3}{4} \Delta_1(w) + \sum_{a=1}^{3} H(w, p_a) \varpi_a(w, w), \\
\tilde{g}_2(w) &= \frac{5}{16} \Delta_1^2(w) + \frac{3}{8} \Delta_2(w) \\
&\quad + \sum_{a=1}^{3} H(w, p_a) \varpi_a(w, w) \left( \frac{1}{w - p_{a+1}} + \frac{1}{w - p_{a+2}} - \Delta_1(w) \right), \\
f_{3/2}(w) &= \frac{\Omega'(w)}{\Omega(w)} + \frac{\Omega(q_1)}{\Omega(w)} S(w, q_1) \psi_1^*(w) + \frac{\Omega(q_2)}{\Omega(w)} S(w, q_2) \psi_2^*(w), \\
\tilde{g}_{3/2}(w) &= \frac{1}{2} \frac{\Omega'(w)}{\Omega(w)} + \frac{1}{32} (S_1(w))^2 \\
&\quad + \frac{\Omega(q_1)}{\Omega(w)} S(w, q_1) \partial \psi_1^*(w) + \frac{\Omega(q_2)}{\Omega(w)} S(w, q_2) \partial \psi_2^*(w).
\end{align*}

As we said in the last section we will take the limit of \( w \to q_1 \). In this limit \( T_{\beta\gamma}(w) \) is singular and we have the following expansion:

\[ T_{\beta\gamma}(w) = -\frac{3}{2} \frac{\partial \psi_1^*(q_1)}{(w - q_1)^2} - \frac{\partial \psi_1^*(q_1)}{w - q_1} - \frac{1}{8} \Delta_1^2(q) - \frac{1}{32} S_1^2(q) + O(w - q_1). \]

The dependence on the abelian differential \( \Omega(z) \) drops out. These singular terms are cancelled by similar singular terms in \( \tilde{B}_{3/2}(w) \). By explicit computation we have: The dependence on the abelian differential \( \Omega(z) \) drops out. These singular terms are cancelled by similar singular terms in \( \tilde{B}_{3/2}(w) \). By explicit computation we have:

\[ \tilde{B}_{3/2}(w) = \frac{3/2}{(w - q_1)^2} + \frac{\partial \psi_1^*(q_1)}{w - q_1} - \frac{1}{4} \Delta_1^2(q) + \frac{3}{4} \Delta_2(q) \]
\[-\left(\frac{1}{p_1 - q} \frac{(q - p_2)(q - p_3)}{(p_1 - p_2)(p_1 - p_3)} \Delta_1(q) + \ldots\right)\]
\[-\frac{3}{2} \left(\frac{1}{(p_1 - q)^2} \frac{(q - p_2)(q - p_3)}{(p_1 - p_2)(p_1 - p_3)} + \ldots\right) + O(w - q_1). \tag{44}\]

where \ldots indicates two other terms obtained by cyclic permuting \((p_1, p_2, p_3)\).

By using the above explicit result we see that the combined contributions of \(T_{\beta\gamma}(w)\) and \(\tilde{B}_{3/2}(w)\) are non-singular in the limit of \(w \to q_1\). We can then take \(\tilde{p}_1 \to q_1\) in \(X_2 + X_3\). In this limit only \(a = 1\) contributes to \(X_2 + X_3\). This is because \(\tilde{\omega}_{2,3}(q_1, q_2) = 0\) and \(\tilde{\omega}_1(q_1, q_2) = -1\). \(T_1(w)\) and \(T_{bc}(w)\) are regular in this limit and spin structure independent. In summary, the spin structure dependent factors from \(X_2 + X_3\) are the following two kinds (not including the vertex operators which will be considered later in section 6):

\[S_1(q) \propto S(q_1, q_2), \quad (S_1(q))^3. \tag{45}\]

Here we note that if we don’t take the limit of \(w \to q_1\) (or \(w \to q_2\) which has the same effect), the spin structure dependent factors from \(X_2 + X_3\) would be much more complicated. For example we will have a factor of the following kind:

\[S_1(q)(S_1(w))^2. \tag{46}\]

The summation over spin structure with this factor will give a non-vanishing contribution as we will see later in eq. (71). We will discuss this point later in section 7.

Finally we come to \(X_1 + X_6\). By using the explicit results given in eqs. (15)–(16), we have

\[X_1 + X_6 = \langle \partial X(q_1) \cdot \partial X(q_2) \rangle S(q_1, q_2)\]
\[-(\partial_{q_1} G_2(q_1, q_2) + \partial_{q_2} G_2(q_2, q_1)) S(q_1, q_2)\]
\[+2(G_2(q_1, q_2) + G_2(q_2, q_1))\]
\[\times (\partial \psi_1^*(q_1) S(q_1, q_2) - \partial q_2 S(q_1, q_2)). \tag{47}\]

As \(G_2(q_1, q_2)\) is spin structure independent, we see that all the spin structure dependent factors are the following two kinds:

\[S(q_1, q_2) = \frac{i}{4} S_1(q), \tag{48}\]

and

\[\partial_{q_2} S(q_1, q_2) = \frac{i}{8} S_2(q). \tag{49}\]
Here it is important that the factor $\partial \psi_1^*(q_2)$ cancels the factor $S(q_1, q_2)$ appearing in the denominator of $f^{(1)}_{3/2}(q_2)$.

From all the above results we see that all the spin structure dependent parts (for the cosmological constant) are as follows:

$$c_1 S_1(q) + c_2 S_2(q) + c_3 S_3^3(q) + \sum_{a=1}^3 d_a S_1(p_a),$$  \hspace{1cm} (50)

where $c_{1,2,3}$ and $d_a$’s are independent of spin structure. In computing the $n$-particle amplitude there are more spin structure factors coming from the correlators of $\psi$. We will include these terms when we discuss the non-renormalization theorem.

## 5 The vanishing of the cosmological constant

The vanishing of the cosmological constant is proved by using the following identities:

$$\sum_\delta \eta_\delta Q_\delta S_n(x) = 0, \hspace{1cm} (51)$$

$$\sum_\delta \eta_\delta Q_\delta S_1^3(x) = 0, \hspace{1cm} (52)$$

for $n = 1, 2$ and arbitrary $x$. Let us explain these identities in detail.

First we write down explicitly the simplest example:

$$M(x, a) = \sum_\delta \eta_\delta \prod_{i<j} (A_i - A_j)(B_i - B_j) \sum_{k=1}^3 \left[ \frac{1}{x - A_k} - \frac{1}{x - B_k} \right]. \hspace{1cm} (53)$$

By a Mobius transformation we have:

$$M(x, a) = y^4(x) \sum_\delta \eta_\delta \prod_{i<j} (\tilde{A}_i - \tilde{A}_j)(\tilde{B}_i - \tilde{B}_j) \sum_{k=1}^3 [\tilde{A}_k - \tilde{B}_k]$$

\hspace{1cm} \equiv y^4(x) M(\tilde{a}), \hspace{1cm} (54)

where $\tilde{a}_i = \frac{1}{x - a_i}$.

As it was shown in [5], there is a unique set of phases $\eta_\delta$ for which $M(a)$ (and $M(x, a)$) is modular invariant in the following sense: for every interchanging $a_i \leftrightarrow a_j \ (i \neq j)$, $M(a)$ got an overall “−” sign, i.e. $M(a)$ is
antisymmetric for every interchange of the branch point \(a_i\)'s. The phases are:

\[
\eta_1 = -\eta_2 = \eta_3 = -\eta_4 = \eta_5 = -\eta_6 = \eta_7 = -\eta_8 = \eta_9 = \eta_{10} = 1. \tag{55}
\]

It is tedious to check explicitly that \(M(a)\) is indeed antisymmetric for every interchange of the branch points by using the above set of phases. In doing so we see quite clearly that the factor \(\sum_{k=1}^{3}[A_k - B_k]\) is also important because sometimes it also gives a "-" sign when we interchange \(a_1\) with other branch points.

Here we remark that eq. (51) is still true if we neglect the factor \(S_1(x)\). In fact these are exactly the Riemann identities for the \(\theta\)-constants by using the Thomae formula [27]:

\[
\Theta_4^1(0) = \pm \det^2 K \prod_{i<j} A_{ij} B_{ij}. \tag{56}
\]

There are 6 set of phases which satisfies eq. (51). These correspond to the convention of setting \(A_1\) to be any of the one fixed branch points, i.e. a choice of odd spin structures. As we can see from the above, a Riemann identity expression is not fully modular invariant and it is only invariant under the subgroup of modular transformations which leaves the fixed branch point invariant, i.e. any interchange of \(a_i \leftrightarrow a_j\) but not with \(A_1\). Even if the Riemann identities guarantees the vanishing of the cosmological constant if we blindly neglect the extra factors \(S_1(x)\) and \(S_3^1(x)\), they are not powerful enough to prove the non-renormalization theorem, not mentioning the explicit computation of the possibly non-vanishing 4-particle amplitude. (See more about this point at the end of this section.)

Now we proved that \(M(a)\) is indeed modular invariant, it is trivial to prove that it is 0. The trick is as follows (which is quite useful in what follows in the proof of non-renormalization theorem and the calculation of the four-particle amplitude). Because \(M(a)\) is a homogeneous polynomial (of degree of 7) in \(a_i\) and it is vanishing whenever \(a_i = a_j\), it should be proportional to \(P(a) \equiv \prod_{i<j}(a_i - a_j)\) which is a homogeneous polynomial of degree 15 in \(a_i\). One see immediately that the power of \(a_i\) can't be matched. So \(M(a)\) must vanish. An explicit computation by computer also verifies this result.

\(^2\)Expanding \(Q_5\) gives 36 different terms and multiplying with \((A_1 + A_2 + A_3 - B_1 - B_2 - B_3)\) gives 72 different terms. So we have 720 terms in the sum which must cancel each other.
The other identities in eq. (51) and eq. (52) can be proved similarly. We note that the power 3 in eq. (52) is important to make the expression modular invariant. In fact for all odd powers \( n \), the following expression is modular invariant:

\[
M_{1,n}(x,a) = \sum_\delta \eta_\delta Q_\delta S_1^n(x).
\]

(57)

By power counting we have

\[
M_{1,n}(x,a) = 0, \quad \text{for } n = 1, 3, 5, 7.
\]

(58)

\( M_{1,9}(x,a) \) has the right power to be non-vanishing and we have

\[
M_{1,9}(x,a) = \frac{21 \times 2^9 \times P(a)}{y^6(x)}.
\]

(59)

For \( n = 11 \) the resulting summation is also quite simple and we have:

\[
M_{1,11}(x,a) = \frac{33 \times 2^9 \times P(a)}{y^6(x)} \times (6\Delta_2(x) - \Delta_1^2(x)).
\]

(60)

For even \( n \) we have the following results:

\[
M_{1,2}(x,a) = 0,
\]

(61)

\[
M_{1,4}(x,a) = \frac{32P(a)(x - a_1)^4}{y^3(x)\Pi_{i=2}^6(a_1 - a_i)}.
\]

(62)

From the above results we see that although \( M_{1,2n}(x,a) \) is not modular invariant, it is invariant under a subgroup of the full modular transformation. This subgroup of modular transformations leaves \( a_1 \) fixed. This also explains why \( M_{1,2}(x,a) \) is vanishing because it should proportional to a homogeneous polynomial \( \tilde{P}(a) = \Pi_{i<j}^6(a_i - a_j) \) which has degree 10 while \( M_{1,2}(x,a) \) is only a homogeneous polynomial of degree 8 apart from the factor \( y^4(x) \).

6 The non-renormalization theorem

For the non-renormalization theorem we need more identities. For graviton and the antisymmetric tensor the vertex operator is (left part only):

\[
V_i(k_i, \epsilon_i, z_i) = (\epsilon_i \cdot \partial X(z_i) + i k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i)) e^{ik_i \cdot X(z_i, \bar{z}_i)}.
\]

(63)
By including the vertex operators we need to consider the following extra spin structure dependent terms:

from $\mathcal{X}_1 + \mathcal{X}_6$ : \[ \langle \psi(q_1) \psi(q_2) \prod_i k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle, \quad (64) \]

from $\mathcal{X}_2 + \mathcal{X}_3$ : \[ S_1(q) \langle \psi(q_1) \cdot \partial \psi(q_1) : \prod_i k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle. \quad (65) \]

The other terms are just the direct product of eq. (50) with the correlators from the vertex operators $\langle \prod_i k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle$. Let’s study these direct product terms (may be called as disconnected terms) first.

To prove the non-renormalization theorem we restrict our attention to 3 or less particle amplitude. For the 3-particle amplitude we have

\[ \langle \prod_{i=1}^3 k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle \propto S(z_1, z_2)S(z_2, z_3)S(z_3, z_1) + \text{(other terms)}. \quad (66) \]

By using the explicit expression of $S(z_1, z_2)$ we have

\[ S(z_1, z_2)S(z_2, z_3)S(z_3, z_1) = \frac{1}{8z_{12}z_{23}z_{31}} \left\{ 2 \left[ \frac{u(z_1)}{u(z_2)} + \frac{u(z_2)}{u(z_1)} \right] + \left[ \frac{u(z_1)}{u(z_3)} + \frac{u(z_3)}{u(z_1)} \right] + \left[ \frac{u(z_2)}{u(z_3)} + \frac{u(z_3)}{u(z_2)} \right] \right\}. \quad (67) \]

These factors combined with the other factors in eq. (50) give vanishing contribution to the $n$-particle amplitude by using the following “vanishing identities”:

\[ \sum_{\delta} \eta_\delta Q_\delta \left\{ \frac{u(z_1)}{u(z_2)} + \frac{u(z_2)}{u(z_1)} \right\} S_{n}(x) = 0, \quad n = 1, 2, \quad (68) \]

\[ \sum_{\delta} \eta_\delta Q_\delta \left\{ \frac{u(z_1)}{u(z_2)} - (-1)^n \frac{u(z_2)}{u(z_1)} \right\} (S_1(x))^n = 0, \quad n = 2, 3. \quad (69) \]

These identities can be proved by modular invariance and simple “power counting” which we have explained in detail in the last section.

Here we want to stress the importance of the limit $\tilde{p}_1 \to q_{1,2}$. For arbitrary $\tilde{p}_a$, we would have a spin structure dependent factor $S_1(q)(S_1(\tilde{p}_a))^2$ from $\mathcal{X}_{2,3}$ (specifically from $T_\psi$, and other terms from $T_{\beta\gamma}$ or $\tilde{B}_{3/2}(\tilde{p}_a)$ are more
complicated as one can see from eqs. (41) and (42)). So we need to compute the following expression:

$$
\sum_\delta \eta_\delta Q_\delta \left\{ \frac{u(z_1)}{u(z_2)} + \frac{u(z_2)}{u(z_1)} \right\} S_1(q) (S_1(\tilde{p}_a))^2.
$$

(70)

Unfortunately the above expression is not identically 0. We have:

$$
\sum_\delta \eta_\delta Q_\delta S_1(x) \left\{ \frac{u(z_1)}{u(z_2)} + \frac{u(z_2)}{u(z_1)} \right\} \left[ \sum_{i=1}^3 (A_i - B_i) \right]^2 = \frac{8P(a)(x - z_1)(x - z_2)}{y^2(x)y(z_1)y(z_2)} (z_1 - z_2)^2.
$$

(71)

Our conjecture is that the combined result would still be 0 and independent of \(\tilde{p}_a\)’s. Nevertheless the above limit of \(\tilde{p}_1 \rightarrow q_{1,2}\) greatly simplifies the algebra in the sense of making each term to be 0 identically. This limit also makes the computation of the four-amplitude doable (otherwise the algebra would be much more complicated). Now we turn our attention to the “disconnected” terms appearing in eqs. (64) and (65).

The terms in eq. (64) have already been discussed in [6]. Here we briefly review the argument. We have

$$
\langle \psi(q_1)\psi(q_2) \prod_i k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle \propto S(q_1, z_1)S(z_1, z_2)S(z_2, z_3)S(z_3, q_2) + \cdots.
$$

(72)

By using the explicit expression of \(S(z, w)\) and note that \(u(q_2) = -u(q_1)\) we have

\[
S(q_1, z_1)S(z_1, z_2)S(z_2, z_3)S(z_3, q_2) \propto \sum_{i=1}^3 \left[ \frac{u(q_1)}{u(z_i)} - \frac{u(z_i)}{u(q_1)} \right] + \sum_{i<j}^3 \left[ \frac{u(z_i)}{u(z_j)} - \frac{u(z_j)}{u(z_i)} \right] + \frac{u(q_1)u(z_2)}{u(z_1)u(z_3)} - \frac{u(z_1)u(z_3)}{u(q_1)u(z_2)}. \tag{73}
\]

These terms also give vanishing contributions as we can prove the following identities:

$$
\sum_\delta \eta_\delta Q_\delta \left\{ \frac{u(z_1)}{u(z_2)} - \frac{u(z_2)}{u(z_1)} \right\} = 0,
$$

(74)

$$
\sum_\delta \eta_\delta Q_\delta \left\{ \frac{u(z_1)u(z_2)}{u(z_3)u(z_4)} - \frac{u(z_3)u(z_4)}{u(z_1)u(z_2)} \right\} = 0. \tag{75}
$$

15
These identities were firstly proved in [6]. The proof is quite simple by using modular invariance. For example we have

\[ \sum_{\delta} \eta_{\delta} Q_{\delta} \left\{ \frac{u(z_1)}{u(z_2)} - \frac{u(z_2)}{u(z_1)} \right\} \]

\[ = \frac{1}{y(z_1)y(z_2)} \sum_{\delta} \eta_{\delta} Q_{\delta} \left\{ \prod_{i=1}^{3} (z_1 - A_i)(z_2 - B_i) - \prod_{i=1}^{3} (z_1 - B_i)(z_2 - A_i) \right\} \]

\[ \propto (z_1 - z_2) P(a) \]

\[ \frac{y(z_1)y(z_2)}{y(z_1)y(z_2)}, \quad (76) \]

which must be vanishing as the degrees of the homogeneous polynomials (in \( a_i \) and \( z_j \)) don’t match. Here we have used again the modular invariance of the above expression.\(^3\)

The last term we need to compute is the term in eq. (65). We have

\[ \langle : \psi(q_1) \cdot \partial \psi(q_1) : \prod_{i} k_i \cdot \psi(z_i) \epsilon \cdot \psi(z_i) \rangle_c = K(1,2,3) \]

\[ \times (S(q_1, z_1, z_2, z_3) + S(q_1, z_2, z_3, z_1) + S(q_1, z_3, z_1, z_2) - S(q_1, z_2, z_1, z_3) - S(q_1, z_3, z_2, z_1)), \quad (79) \]

where

\[ K(1,2,3) = k_1 \cdot \epsilon_3 k_2 \cdot \epsilon_1 k_3 \cdot \epsilon_2 \]

\[ + k_1 \cdot k_2 (k_3 \cdot \epsilon_1 \epsilon_2 \cdot \epsilon_3 - k_3 \cdot \epsilon_2 \epsilon_1 \cdot \epsilon_3) \]

\[ + k_2 \cdot k_3 (k_1 \cdot \epsilon_2 \epsilon_3 \cdot \epsilon_1 - k_1 \cdot \epsilon_3 \epsilon_2 \cdot \epsilon_1) \]

\[ + k_3 \cdot k_1 (k_2 \cdot \epsilon_3 \epsilon_1 \cdot \epsilon_2 - k_2 \cdot \epsilon_1 \epsilon_3 \cdot \epsilon_2), \quad (80) \]

\[ S(x, z_1, z_2, z_3) = S(x, z_1)S(z_1, z_2)S(z_2, z_3) \partial_x S(z_3, x). \quad (81) \]

\(^3\)The minus sign in eq. (74) makes the expression invariant under the all the modular transformations. With a plus sign the expression is only invariant under a subgroup of the modular transformation. Nevertheless eq. (74) is still true with a plus sign. The explicit results are:

\[ \sum_{\delta} \eta_{\delta} Q_{\delta} \left\{ \frac{u(z_1)}{u(z_2)} + \frac{u(z_2)}{u(z_1)} \right\} = 0, \quad (77) \]

\[ \sum_{\delta} \eta_{\delta} Q_{\delta} \left\{ \frac{u(z_1)u(z_2)}{u(z_3)u(z_4)} + \frac{u(z_3)u(z_4)}{u(z_1)u(z_2)} \right\} = \frac{2P(a)z_{13}z_{14}z_{23}z_{24} \prod_{i=1}^{4} (a_1 - z_i)}{\prod_{i=1}^{4} y(z_i) \prod_{i=2}^{n} (a_1 - a_i)}. \quad (78) \]
We note that \( K(1, 2, 3) \) is invariant under the cyclic permutations of \((1,2,3)\). It is antisymmetric under the interchange \(2 \leftrightarrow 3\). We have used these properties in eq. (79).

To compute explicitly these expressions we first note the following:

\[
\partial_x S(z, x) = \frac{1}{2(z - x)^2} \frac{u(z) + u(x)}{\sqrt{u(z)u(x)}} - \frac{S_1(x)}{8(z - x)} \frac{u(z) - u(x)}{\sqrt{u(z)u(x)}}.
\] (82)

In order to do the summation over spin structure we need a “non-vanishing identity”. This and other identities needed in the 4-particle amplitude computations are summarized as follows:

\[
\sum_\delta \eta_\delta Q_\delta \left\{ \frac{u(z_1)u(z_2)}{u(z_3)u(z_4)} - (-1)^n \frac{u(z_1)u(z_2)}{u(z_3)u(z_4)} \right\} (S_m(x))^n
\]
\[
= 2P(a) \prod_{i=1}^2 \prod_{j=3}^4 (z_i - z_j) \prod_{i=1}^4 (x - z_i) \frac{y^2(x) \prod_{i=1}^4 y(z_i)}{\prod_{i=1}^4 y(z_i)} \times C_{n,m},
\] (83)

where

\[ C_{1,1} = 1, \] (84)
\[ C_{2,1} = -2(\tilde{z}_1 + \tilde{z}_2 - \tilde{z}_3 - \tilde{z}_4), \] (85)
\[ C_{1,2} = \Delta_1(x) - \sum_{k=1}^4 \tilde{z}_k, \] (86)
\[ C_{3,1} = 2\Delta_2(x) - \Delta_1^2(x) + 2\Delta_1(x) \sum_{k=1}^4 \tilde{z}_k
\]
\[ + 4 \sum_{k<l} \tilde{z}_k \tilde{z}_l - 12(\tilde{z}_1 + \tilde{z}_2)(\tilde{z}_3 + \tilde{z}_4), \] (87)
\[ \tilde{z}_k = \frac{1}{x - z_k}, \] (88)
\[ P(a) = \prod_{i<j} (a_i - a_j). \] (89)

\( C_{1,1} \) and \( C_{1,2} \) were derived in [8]. Although other values of \( n, m \) also gives modular invariant expressions, the results are quite complex.\(^4\) Fortunately we only need to use the above listed results. The proof of these summation formulas will be given in [24].

\(^4\)This is due to the non-vanishing of the summation over spin structures when we set \( z_1 = z_3 \) or \( z_1 = z_4 \), etc.
By using these formulas we have:

\[
\sum_\delta \eta_\delta Q_\delta S(x, z_1, z_2, z_3) S_1(x) = -\frac{P(a)}{16y^2(x)} \prod_{i=1}^3 \frac{x - z_i}{y(z_i)}. \tag{90}
\]

We note that the above formula is invariant under the interchange \( z_i \leftrightarrow z_j \).

By using this result and eq. (79), we have:

\[
\sum_\delta \eta_\delta Q_\delta S(q_1, q_2) \langle \psi(q_1) \cdot \partial \psi(q_1) : \prod_{i=1}^3 k_i \cdot \psi(z_i) \epsilon_i \cdot \psi(z_i) \rangle_\delta = 0. \tag{91}
\]

This completes our verification of the non-renormalization theorem at two loops.
