Abstract
With the shortage of the energy and ever increasing of the oil price, research on the renewable and green energy sources, especially the solar arrays and the fuel cells, becomes more and more important. How to achieve high step-up and high efficiency DC/DC converters is the major consideration in the renewable power applications due to the low voltage of PV arrays and fuel cells. In this paper a coupled inductor dc-dc converter for photovoltaic system is proposed. The circuit configuration of the proposed converter is very simple. Thus, the proposed converter has higher step-up and step-down voltage gains than the conventional bidirectional dc-dc boost/buck converter. Under same electric specifications for the proposed converter and the conventional bidirectional boost/buck converter, the average value of the switch current in the proposed converter is less than the conventional bidirectional boost/buck converter. The operating principles have been applied to multi input photovoltaic system and outputs have been observed.

Index terms: boost, pv array, coupled inductor, stepup/step down.

I. Introduction
The massy usage of the fossil fuels, such as the oil, the coal and the gas, result in serious greenhouse effect and pollute the atmosphere, which has great effect on the world. Meanwhile, there is a big contradiction between the fossil Fuels supply and the global energy demand, which leads to a high oil price in the international market recently. The energy shortage and the atmosphere pollution have been the major limitations for the human development. How to find renewable energy is becoming more and more exigent.

As the output voltage of the solar panel is very low and there should be a clear transformation for such low voltage to high voltage. Hence such work could be done by boost converter. The dc-dc boost converters are used to convert the unregulated dc input to a controlled dc output at a desired voltage level. They generally perform by applying a dc voltage across an inductor or transformer a period of time (usually in the 20 kHz to 5 MHz range) which causes current to flow through it and store energy magnetically, then switching this voltage off and causing the stored energy to be transferred to the voltage output in a controlled manner. The output voltage is regulated by adjusting the ratio of on/off time.

II. Photovoltaic Array
PV array’s output current-voltage curve reflects PV array’s dependence on environmental conditions such as ambient temperature and illumination level. Typically, the illumination level ranges from 0 to 1100Wb/m² and the temperature range is between 233 and 353 K. Normally, we select 1100 and 298 as the reference values for illumination level and temperature respectively. The relationship between PV array’s output characteristics and environmental conditions could be illustrated from general simulation results of PV array. PV array’s output power is increased as illumination level increases, while PV array’s output power is improved with the decrease of the ambient temperature. The equivalent circuit of a typical pv-cell is given below.

Figure reflects a simple equivalent circuit of a photovoltaic cell. The current source which is driven by sunlight is connected with a real diode in parallel. In this case, PV cell presents a p-n junction characteristic of the real diode. The forward current could flow through the diode from p-side to n-side with little loss. However, if the current flows in
reverse direction, only little reverse saturation current could get through. All the equations for modeling the PV array are analyzed based on this equivalent circuit.

### III. Coupled inductor Boost converter

Bidirectional dc–dc converters are used to transfer the power between two dc sources in either direction. These converters are widely used in applications, such as hybrid electric vehicle energy systems, uninterrupted power supplies, fuel-cell hybrid power systems solar photovoltaic hybrid power systems and battery chargers. Many bidirectional dc–dc converters have been researched. The bidirectional dc–dc fly back converters are more attractive due to simple structure and easy control. However, these converters suffer from high voltage stresses on the power devices due to the leakage inductor energy of the transformer. In order to recycle the leakage inductor energy and to minimize the voltage stress on the power devices, some literatures present the energy regeneration techniques to clamp the voltage stress on the power devices and to recycle the leakage inductor energy. Some literatures research the isolated bidirectional dc–dc converters, which include the half-bridge and full-bridge types. These converters can provide high step-up and step-down voltage gain by adjusting the turns ratio of the transformer. The multilevel type is a magnetic less converter, but 12 switches are used in this converter.

A modified dc–dc boost converter is presented the voltage gain of this converter is higher than the conventional dc–dc boost converter. Based on this converter, a novel bidirectional dc–dc converter is proposed, as shown in Fig. 2. The proposed converter employs a coupled inductor with same winding turns in the primary and secondary sides. Comparing to the proposed converter and the conventional bidirectional boost/buck converter, the proposed converter has the following advantages: 1) Higher step-up and step-down voltage gains and 2) lower average value of the switch current under same electric specifications. The following sections will describe the operating principles and steady-state analysis for the step-up and step-down modes. In order to analyze the steady-state characteristics of the proposed converter, some conditions are assumed: The ON-state resistance $R_{DS(ON)}$ of the switches and the equivalent series resistances of the coupled inductor and capacitors are ignored; the capacitor is sufficiently large; and the voltages across the capacitor can be treated as constant.

### 3.1 Step-Up Mode

The proposed converter can be used for both step up and step down modes with suitable switching of the devices. The proposed converter in step-up mode is shown in Fig. 3. Since the primary and secondary winding turns of the coupled inductor is same, the inductance of the coupled inductor in the primary and secondary sides are expressed as

$$L_1 = L_2 = L.$$  \hspace{1cm} (1)

Thus, the mutual inductance $M$ of the coupled inductor is given by

$$M = k\sqrt{L_1L_2} = KL.$$  \hspace{1cm} (2)

Where $k$ is the coupling coefficient of the coupled inductor. The voltages across the primary and secondary windings of the coupled inductor are as follows:

$$v_{L1} = L_1\frac{dI_{L1}}{dt} + M\frac{dI_{L2}}{dt} = L\frac{dI_{L1}}{dt} + kL\frac{dI_{L2}}{dt}.$$  \hspace{1cm} (3)

$$v_{L2} = M\frac{dI_{L1}}{dt} + L_2\frac{dI_{L2}}{dt} = kL\frac{dI_{L1}}{dt} + L\frac{dI_{L2}}{dt}.$$  \hspace{1cm} (4)

Since the proposed converter can be used for both continuous (CCM) and discontinuous conduction (DCM) only the continuous conduction mode (CCM) is preferred for the analysis for best understanding of the operation.

### 3.2 CCM operation

**Mode 1:** During this time interval $[t_0, t_1]$, S1 and S2 are turned on and S3 is turned off. The current flow path is shown in Fig. 3(a). The energy of the low-
voltage side \( VL \) is transferred to the coupled inductor. Meanwhile, the primary and secondary windings of the coupled inductor are in parallel. The energy stored in the capacitor \( CH \) is discharged to the load. Thus, the voltages across \( L1 \) and \( L2 \) are obtained as

\[
V_L = V_{L1} = V_{L2} = \frac{1}{2} (V_L - V_H)
\]

Substituting (3) & (4) in (5) we get

\[
\frac{d}{dt} i_{L1}(t) = \frac{i_{L2}(t)}{L}, \quad t_3 \leq t \leq t_4
\]

**Mode 2:** During this time interval, \( S1 \) and \( S2 \) are turned off and \( S3 \) is turned on. The current flow path is shown in Fig. The low-voltage side \( VL \) and the coupled inductor are in series to transfer their energies to the capacitor \( CH \) and the load. Meanwhile, the primary and secondary windings of the coupled inductor are in series. Thus, the following equations are found to be

\[
i_{L1} = i_{L2}
\]

\[
u_{L1} + u_{L2} = V_L - V_H
\]

By substituting above equations we get

\[
\frac{d}{dt} i_{L1}(t) = \frac{d}{dt} i_{L2}(t) = \frac{V_L - V_H}{2(1+k)L}, \quad t_1 \leq t \leq t_2
\]

By using the state-space averaging method, the following equation is derived from

\[
\frac{dV_L}{(1+k)L} + \frac{(1-D)(V_L - V_H)}{2(1+k)L} = 0
\]

By simplifying we get

\[
G_{CCM}(step-up) = \frac{V_H}{V_L} = \frac{1 + D}{1 - D}
\]

**IV. Matlab Model of Coupled Inductor DC Converter for PV System**

The proposed system was developed on Matlab/simulink in a lucid fashion and in the simple way. The model was simulated only for two inputs and can be further added depending on the requirement. The converters use two coupled inductances of same value. Typically we took a Mutual inductance block and is modeled for two windings only. The temperature of the PV panel is assumed to be 25 K and irradiance constant is assumed to be maintained at 1000. The devices were switched at high frequency. It has to be noted that \( S1 \& S2 \) – ON, \( S3 \)-OFF and vice versa.

V. Simulation results

The performance of the proposed converter was verified using MATLAB/simulink. Some experimental results in step-up are shown in Fig 5, shows the waveforms of the total input current $i_L$ and the coupled inductor currents $i_{L1}$ and $i_{L2}$ in step-up mode. It can be observed that $i_{L1}$ is equal to $i_{L2}$.

VI. Conclusion

The proposed dc converter is simple in construction and has more efficiency than the conventional dc-dc converter. This can be used in battery operated vehicles, and solar powered uninterrupted power supplies and can have significant use in renewable energy sources where there is a need of efficient dc conversion.
