This study presents the treatment of 68 children with secretory otitis media. Children underwent adenoid vegetations, nasal speech, conductive hearing loss, ventilation disturbance in Eustachian tube. In all children adenoidectomy was indicated. 38 boys and 30 girls at the age of 3-17 were divided in two main groups:

- 29 children without hypertrophic (enlarged) adenoids,
- 39 children with enlarged (hypertrophic) adenoids.

The surgical treatment included insertion of ventilation tubes and adenoidectomy where there where hypertrophic adenoids.

Clinical material was analyzed according to hearing threshold, hearing level, middle ear condition estimated by pure tone audiometry and tympanometry before and after treatment. Data concerning both groups were compared.

The results indicated that adenoidectomy combined with the ventilation tubes facilitates secretory otitis media healing as well as decrease of hearing impairments. That enables prompt restoration of the hearing function as an important precondition for development of the language, social, emotional and academic development of children.

**Key words**: adenoid vegetations, nasal speech, secretory otitis media

Introduction

Secretory otitis media (SOM) is one of the most common childhood concerns mainly in preschool and school children. SOM is a collection of fluid in the tympanic cavity without the signs and symptoms of acute inflammation. Abnormal Eustachian tube function appears to be the most important factor in the pathogenesis of SOM. Children with SOM typically have rather elevated, fluctuating hearing thresholds of about 20-25 dB (1, 6). They complain of ear fullness or tinnitus (1, 3).

Diagnostic accuracy of SOM can be confirmed by the tympanometry. Those measurements provide an objective assessment of middle ear pressure and tympanic compliance. Usually we obtain B tympanogram, sometimes C tympanogram occurs (Berry et al., 1975). In literature, the influence of adenoids, their size and adenoidectomy on secretory otitis media seems to be controversial. Some authors maintain that enlarged adenoid influence considerably the illness and others do not observe a significant difference in SOM occurrence with or without enlarged (hypertrophic) adenoids. (Cowenberge et al. 1995) (3).

The aim of the study is to answer the question whether the presence of enlarged adenoid influences frequency, clinical course of the disease on the bases of the treatment results of SOM (4, 5 and 6).

Material and Methods

Subjects of the clinical investigation were a group of 68 children at the age of 3-17. Accordingly to the clinical examination (digital assessment and nasofiberscope) children were divided into 2 groups.

The first group consisted of 29 children without enlarged (hypertrophic) adenoids and the second group consisted of 39 children with enlarged (hypertrophic) adenoids.
Kaj decata od prvata grupa bea postaveni ventilaci oni ceviwa, a kaj decata od vtorata grupa pokraj ventilaci oni ceviwa be e napraveno i adenoide dektomija. Tonal no audiometriisko i spituwave i timpanometrija be e napravena pred i po operaci jata so pomo ka aparatura (audiometer-Hortman CA 540) i kliniki ki timpanometar (Hortman tip 87). Ne postoe e si signifikantna razlika vo ?2-testot meju sitet grupi (p>0,05) (Slika 1).

Poreju 68 deca so SOM, 39 (57%) ima hi pertrof i-ni adenoidi, ?2 testot pokaz deka SOM se pojavuva i vo dvete grupi na deca (oni e koi i maat oni e koi nemaat hi pertrof i-ni adenoidi). Spored testot na i pendaranca (?2 = 0.927, p>0.05), vo grupata I i vo grupata II fekfencijata na pojana na SOM na edno ili pak na dvete u{i e sli -na (Slika 2).

Rezultatite
Rezultatite se izrazeni kako prose ni vrednosti vo razlikata pomeju koskenata i vozduhata sprovodlivost pred i po hi - ruri kot tretman. Ne se doka' asignifikantna razlika meju decata so SOM so i bez hi pertrofi -ni adenoidi. Timpanometriski testovi pokaz deka frekfencijata na edno ili dvete u{i e sli -na vo dvete grupi. Evulacija na rezultatite od sprovodni ot tretman se bazira na promenite koi bea registrirani natimpanogramot (5).

Tie ukas deka tretmanot e poefikasni i restarvacijata na sluhot e pobrza kaj deca so SOM od vtorata grupa. (?2=1.62 p=0.02)

Ventilation tubes were inserted in children from the first group, and the children from the second group underwent adenoidectomy and ventilation tube insertion. The pure tone audiometry and tympanometry were performed pre and postoperatively using audiological equipment (Audiometer Hortman CA 540) and clinical tympanometer (Hortman type 87). There was not a significant difference in ?2-test between the groups (p>0.05) (Fig. 1.).

Among 68 children with SOM, 39 (57%) had enlarged adenoids, ?2 test shows that SOM occurs with the same probability in children with and without enlarged adenoid. According to the independence test (?2=0.927, p>0.05) in the first and the second group, the frequency of affection of one or both ears in children with SOM are similar (Fig. 2).

Results
The treatment results were expressed as an average air bone conduction pure tone, and air-bone gap difference in pre and post surgical procedure. No significant difference was shown between children with SOM with or without hypertrophic adenoids.

All tympanograms tests showed that the frequency of affection of one or both ears in children with SOM is similar in both groups. Evaluation of treatment efficiency was conducted basing on changes registered on the tympanogram (5). They showed that the treatment is more efficient and the restoration of hearing is quicker in children with SOM from the second group. (?2=1.62 p=0.02).

Discussion

Many clinicians emphasize the great influence of enlarged adenoid on SOM occurrence. Some investigators do not agree with this theory. Lack of agreement over methodology, different selection methods can partially explain these different opinions.

In our material among children undergoing ventilation tube insertion, in the second group enlarged adenoids were confirmed and they request adenoidectomy.

All our observations and other author opinions indicate profitable influence of the enlarged adenoid removal on healing process after ventilation tube insertion in SOM (6, 7). This may result from the infection source removal and restoration of the nasopharynx and Eustachian tube.
