The dynamical effects of solar magnetoconvection span a wide range of spatial and temporal scales that extend from the interior to the corona and from fast turbulent motions to global magnetic activity. To study the solar activity on short temporal scales (from minutes to hours), we use 3D radiative MHD simulations that allow us to investigate complex turbulent interactions that drive various phenomena, such as plasma eruptions, spontaneous formation of magnetic structures, funnel-like structures and magnetic loops in the corona, and others. In particular, we focus on multi-scale processes of energy exchange across layers of the solar interior and atmosphere, which contribute to coronal heating and eruptive dynamic modeling global-scale activity, we use a data assimilation approach that has demonstrated great potential for building reliable long-term forecasts of solar activity. In particular, it has been shown that the Ensemble Kalman Filter (EnKF) method applied to the Parker-Kleorin-Ruzmaikin dynamo model is capable of predicting solar activity up to one sunspot cycle at a time, as well as estimating the properties of the next cycle a few years before it begins. In this presentation, using the available magnetogram data, we discuss development of the methodology and forecast quality criteria (including forecast uncertainties and sources of errors). We demonstrate the influence of observational limitations on prediction accuracy, and present the EnKF predictions of the upcoming Solar Cycle (25) based on both the sunspot number series and observed magnetic fields and discuss the uncertainties and potential of the data assimilation approach for modeling and forecasting solar activity.

StellarBox' code (Wray et al., 2018)

- 3D rectangular geometry
- Fully conservative, Fully compressible
- Fully coupled radiation solver:
- Non-ideal (tabular) EOS
- 4th order Godunov discretization
- 4th order Runge-Kutta time integration
- Turbulence models:
- Compressible Smagorinsky model
- Compressible Dynamics Smagorinsky mode (Germano et al., 1991; Moin et al., 1991)
- MHD subgrid models (Balarać et al., 2010)
- DNS-Hyperviscosity approach
- MPI parallelization (plane and pencil versions)

Flow eruptions

Structure of the flow during the eruption. The vortex core is shown as an isosurface of temperature. Streamlines illustrate the structure of the velocity field in the vicinity of the vortex core.

Eruptive dynamics: hydrodynamic vs magnetic forces

Conclusions I

To investigate the underlying physical processes, we performed 3D radiative MHD simulations, taking into account all essential physics and employing sub-grid scale turbulence models, and reproduce the local dynamo process, spontaneous flow eruptions, and coronal structure and dynamics in the quiet-Sun. The simulations revealed three important properties of the dynamo-generated magnetic fields: 1) strong coupling of various magnetic field amplification mechanisms, which leads to increased local magnetic energy, 2) the multi-scale nature of the dynamo process, which involves turbulent flows from the smallest resolved scales to granular scales, 3) a complex topological and dynamical structure of the process, which is reflected in the interaction of individual magnetic patches and surrounding magnetic fields and in the self-organization that produces a magnetic network. Our simulations reveal penetration of vortex tubes from the photosphere into the corona. The vortex tube eruptions cause significant qualitative changes in atmospheric dynamics, such as strong variations in the thermodynamic structure, magnetic field-line topology, and local heating, and are also a source of local twisted outflows in the corona. The plasma flow in the eruptions is accelerated by the Lorentz force from 6 to 12–15 km/s in higher (mid-chromospheric) layers. Using an advanced 3D radiative MHD code, "StellarBox", we have performed the first high-resolution simulations of the Sun from the deep convection zone to the corona. It is found that the transition zone between the low temperature (10⁴ K) chromosphere and hot (10⁶ K) corona is substantially more turbulent and dynamic than previously assumed. The simulations revealed new processes of generation of shocks and plasma eruptions and showed that transition-region dynamics is a source of coronal expansion and formation of the solar wind.

Magnetic field distribution at the photosphere

Magnetic structures formed by a turbulent dynamo on the Sun, generated from an initial random seed field. The blue-red color scale corresponds to magnetic field strength from -300 to 300 Gauss. The typical size of the magnetic structures is 100 to 300 km.

Modeling of self-organization processes in the solar corona

Data Assimilation Methodology

'Prediction' of Cycles 23 and 24 for both hemispheres using reconstructed toroidal and poloidal magnetic field components

Synoptic magnetogram. The color scale is saturated at +/-15G. The yellow dashed lines indicate different moments of time: 1992 and 1994.

Solar Cycle 25 prediction

Uncertainties in Prediction of Solar Cycle 25 using sunspot number records

Comparison of hemispheric sunspot numbers, observed and inferred from magnetograms

Results of magnetic field decomposition into dynamical and poloidal field components from the radial field synoptic magnetograms.

Conclusions II

In this work we take advantage of synoptic observations of the solar magnetic field emerging on the surface of the Sun. The observational data are assimilated into a dynamo model which provides a theoretical description of the generation and evolution of the global magnetic field on the Sun. Using the currently available observational data and prediction uncertainties calculated for Solar Cycle 25. The results based on the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end). The model results show that the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end). The model results show that the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end). The model results show that the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end). The model results show that the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end). The model results show that the sunspot number series and observed magnetic field indicate that the upcoming Solar Maximum (SC25) is expected to be weaker than that of the previous cycle (SC24). The model results show that the maximum of the solar cycle will occur in 2024 (which is near its end).
