A COMPUTER PROGRAM FOR THE PREDICTION OF
DUCTED FAN PERFORMANCE

By Michael R. Mendenhall and Selden B. Spangler
Nielsen Engineering & Research, Inc.

SUMMARY

This document is a user's manual for a computer program developed to determine the performance of a ducted fan in axial flow and at angle of attack. The program is used to predict the performance at a specified advance ratio and angle of attack of a given fan-duct combination, which is specified by the radial distributions of blade pitch, chord, and thickness; the duct chord, diameter, camber, and thickness distribution; the fan location; and the centerbody geometry. The information obtained from the program is duct and fan thrust and ducted fan normal force and pitching moment coefficient. Radial distributions of fan inflow velocity and blade angle of attack are also obtained. The program calculates the duct surface pressure distribution at any specified azimuthal angle. The program is written in Fortran IV for the IBM 7094 computer and requires approximately two minutes running time per case. Included in this manual are a brief description of the theory and the calculation procedure, descriptions of input and output, program listing, sample cases, and some comparisons with data.

1. INTRODUCTION

This report is one of two documents prepared under Contract NAS2-4953 for the Ames Research Center, NASA. The work on this contract is concerned with development of methods for predicting the aerodynamic performance of ducted fans in uniform flow. This document is a user's manual for the computer program developed under the contract. The second document (ref. 1) describes the analysis on which the computer program is based.

The authors and their associates have done a considerable amount of prior work on ducted fan analysis (refs. 2-6). The final task of that work involved the preparation of a computer program for calculating the aerodynamic characteristics of a ducted fan in a uniform, axial

flow (ref. 6). The purpose of the present investigation is to make certain improvements and additions to the computer program of reference 6. The additional analysis required to make these improvements is reported in reference 1. The improvements consist of adding a capability for angle of attack flow, computing duct surface pressure distributions, adding a centerbody model, and removing certain restrictions on advance ratio and nonlinear blade lift characteristics. This report includes a brief discussion of the theoretical approach and the assumed flow model with a summary of the equations used in the program. No derivations are included, but references are given to all the derivations of interest. The actual operation of the program is discussed along with descriptions of input and output. Program listings and sample cases are also included. Some brief comparisons with data are presented to give some information on the range of usefulness of the program. This document completely supersedes reference 6.

2. THEORETICAL APPROACH AND FLOW MODEL

The discussion of this section is intended to describe the theoretical approach in sufficient detail to permit the user of the program to understand the sequence of calculations in the program. The equations in the program are given with references to the source in which each is derived.

The flow model is inviscid and is based on potential flow theory. The approach used is to decouple the axial flow and angle of attack problems, treat each individually, and superimpose the solutions.

2.1 Axial Flow

The analysis for axial flow is basically that described in reference 5 with the modifications and additions described in reference 1. Singularity distributions are used to represent the fan wake, the duct loading, the duct thickness, and the centerbody. The basic axisymmetric flow model is shown in figure 1(a). A duct reference cylinder is defined as that cylinder having the same radius as the duct trailing edge. The reference cylinder is used in conjunction with the boundary condition imposed on the duct.

The duct may have both thickness and camber, and the chord-to-diameter ratio may have any value.¹ The fan configuration is specified by the number of blades (N) and by the radial distribution of chord (b), pitch (β), and thickness (h) as shown in figure 2. The effect of blade camber is not directly considered; however, the pitch angle, β , is assumed to be the angle between the plane of rotation and the zero lift line of the local blade section. Each blade section is assumed to have a lift coefficient slope, $c_{l\alpha}$, of 2π up to the point of local blade stall. This point is assumed to be a function only of the blade thickness-to-chord ratio as described in reference 1. After the blade section stalls, the section lift coefficient is assumed to be constant and equal to $c_{l\max}$. Since blade element theory is used to determine the fan performance, use of the program is limited to ducted fans with relatively low blade solidity. The upper limit on solidity has not been estimated because of the lack of suitable data for comparing predicted and measured performance.

The fan annulus is divided into a number ($z \leq 24$) of equal area annuli in each of which blade element theory is used to describe local blade performance. The bound circulation (Γ) is constant within each annulus and a vortex cylinder with strength γ_w is assumed to be shed from each annulus and to extend downstream along the duct axis. The outer vortex cylinder is assumed to lie along the duct reference cylinder and to be shed from the duct trailing edge.

From equation (5) of reference 5, the bound circulation on the portion of the blade in the w^{th} annulus is

$$\frac{\Gamma_w}{RV} = \frac{1}{2} c_{l\alpha} \frac{b_w}{R} \frac{u_w}{V} \left[\left(\frac{\bar{r}_w \omega}{u_w} \right)^2 + 1 \right]^{1/2} \quad (1)$$

¹There is an upper limit on c/D of approximately 2.5 imposed by the absence of P_{kl} values and induced camber coefficients for c/D values greater than 2. See p. 7 for further details.

and the strength of the w^{th} internal trailing vortex cylinder is

$$\frac{\gamma_w}{V} = \left[\left(1 + \sum_{m=w+1}^z \frac{\gamma_m}{V} \right)^2 + \frac{N}{\pi J'} \left(\frac{\Gamma_w}{RV} - \frac{\Gamma_{w+1}}{RV} \right) \right]^{1/2} - \left(1 + \sum_{m=w+1}^z \frac{\gamma_m}{V} \right) \quad (2)$$

where

$$J' = \frac{V}{R\omega} \quad (3)$$

The strength of the outer vortex cylinder is

$$\frac{\gamma_z}{V} = \left[1 + \frac{N}{\pi J'} \left(\frac{\Gamma_z}{RV} \right) \right]^{1/2} - 1 \quad (4)$$

In many of the following equations, γ is used as a normalizing parameter. When γ is used without a subscript it designates the strength of the outer cylinder, γ_z .

Assuming that the inflow to the fan (u/V) is known, the radial distribution of bound circulation may be calculated using equation (1), and the strength of the vortex cylinders can be obtained from equations (2) and (4). However, the inflow to a fan in a specified duct at a given flight condition is not known a priori. The inflow is made up of the free stream plus the axial velocity components induced by all the singularity distributions. Thus, the inflow to the propeller at a given radial station is

$$\frac{u_m}{V} = 1 + \frac{u_{\gamma_D}}{V} + \frac{u_{\gamma}}{V} + \frac{u_{q_D}}{V} + \frac{u_{CB}}{V} + \frac{1}{2} \sum_{w=m}^{z-1} \frac{\gamma_w}{V} \quad (5)$$

With the exception of the centerbody-induced flow, the components of the inflow velocity are computed in the same manner as is described in Appendix A of reference 5. The velocity (u_{CB}) induced by the centerbody is not considered in reference 5 but is computed using equation (15) of reference 1. The velocities induced by the centerbody must be corrected to account for the fact that the centerbody is submerged in a

free stream greater than V . The details of this correction are presented in reference 1. Note that the inflow profile is dependent on the duct and fan loadings which, in turn, are affected by the inflow profile; therefore, an iterative scheme is used to converge on a solution.

The trailing vortex cylinder, the fan wake vortex cylinders, the centerbody, and the free stream all induce components of flow through the duct camberline. In order to cancel this flow and cause the net flow to be tangent to the camberline, a distribution of bound vorticity (γ_D) is placed on the duct. This bound vorticity is expressed in terms of a Glauert series (eq. (17), ref. 4) as

$$\frac{\gamma_D}{\gamma} = C_0 \cot \frac{\theta}{2} + \sum_{n=1}^5 C_n \sin n\theta \quad (6)$$

and the unknown C_n coefficients are determined from the flow tangency condition on the duct reference cylinder.

The basic relation that is solved to cause the flow to be tangent to the camberline is

$$v_{\gamma_D} + v_{\gamma} + v_{\gamma_w} + v_{CB} = \frac{dr_e}{dx} \left(v + u_{\gamma_D} + u_{\gamma} + u_{\gamma_w} + u_{CB} \right) \quad (7)$$

where dr_e/dx is the effective slope of the camberline. The following procedure is used to solve equation (7) for the unknown C_n coefficients.

The radial velocity (v_{γ}) induced along the duct reference cylinder by the vortex cylinder trailing from the duct trailing edge is given by equation (C-3) of reference 5. This velocity is expressed in non-dimensional form by a six-term Fourier cosine series as

$$\frac{v_{\gamma}}{\gamma} = \sum_{n=0}^5 B_n \cos n\theta \quad (8)$$

The axial velocity (u_γ) induced by the same vortex cylinder is given by equation (23) of reference 3. This velocity is expressed in non-dimensional form by a similar six-term Fourier cosine series as

$$\frac{u_\gamma}{\gamma} = \sum_{n=0}^5 B_n^* \cos n\theta \quad (9)$$

The radial and axial velocities induced along the duct reference cylinder by all the vortex cylinders trailing from the fan are computed using equation (13) and (20), respectively, of reference 3. The sum of the radial and axial velocities induced by all the internal vortex cylinders is expressed as

$$\frac{v_{\gamma w}}{V} = \sum_{n=0}^5 A_n \cos n\theta \quad (10)$$

$$\frac{u_{\gamma w}}{V} = \sum_{n=0}^5 A_n^* \cos n\theta \quad (11)$$

The radial and axial velocities induced along the duct reference cylinder by the centerbody singularity distribution are computed using equations (15) and (16) of reference 1. These velocities are expressed as

$$\frac{v_{CB}}{V} = \sum_{n=0}^5 D_n \cos n\theta \quad (12)$$

$$\frac{u_{CB}}{V} = \sum_{n=0}^5 D_n^* \cos n\theta \quad (13)$$

The slope of the effective camberline is specified as

$$\frac{dr_e}{dx} = \sum_{n=0}^3 R_n^* \cos n\theta \quad (14)$$

where the effective camber is made up of a geometric camber and an induced camber as discussed in detail in section 2.3 of reference 6. The induced camber is due to the velocity induced by the source ring distribution representing the duct thickness, and the method of computing this effect is based on the work described in Chapter 2 of reference 7. The induced camber is described by a Fourier series similar to equation (14) where the first four coefficients are tabulated as a function of c/D in reference 6. These coefficients are included in the program in Subroutine CAMBER and are automatically combined with the geometric camber coefficients. The calculation of the geometric camber coefficients is described in section 4.2 of this report.

The axial velocity induced by the bound vorticity, γ_D , can be written in terms of the C_n coefficients as

$$\begin{aligned} \frac{4D}{c} \frac{u_{\gamma_D}}{\gamma} = & \left(\ln \frac{16D}{c} - 1 \right) \left(C_0 + \frac{C_1}{2} \right) + \left(\frac{2C_0 + C_2}{2} \right) \cos \theta \\ & + \left(\frac{C_3 - C_1}{4} \right) \cos 2\theta + \left(\frac{C_4 - C_2}{6} \right) \cos 3\theta + \left(\frac{C_5 - C_3}{8} \right) \cos 4\theta \end{aligned} \quad (15)$$

from equation (18) of reference 4. The radial velocity component can be found from equation (1.13) of reference 8 as

$$\frac{v_{\gamma_D}}{\gamma} = \frac{C_0}{2} - \sum_{l=0}^5 \frac{C_l}{2} P_{0l} + \sum_{k=1}^5 \cos k\theta \left(-\frac{C_k}{2} + \sum_{l=0}^5 \frac{C_l}{2} P_{kl} \right) \quad (16)$$

where the P_{kl} coefficients are given in tables 2.1 through 2.4 of reference 9. These tables have been extended to c/D values of 2.0, and provision has been made in the program to extrapolate beyond 2.0. However, the variation of P_{kl} with c/D is not linear, and the extrapolation should not be made much past 2.5.

Substituting equations (8) through (16) into equation (7) results in

$$\sum_{n=0}^5 \left(\frac{\gamma}{V} B_n + A_n + D_n \right) \cos n\theta + \frac{\gamma_D}{\gamma} \left(\frac{\gamma}{V} \right) = \sum_{m=0}^3 R_m^* \cos n\theta \left[\sum_{n=0}^5 \left(\frac{\gamma}{V} B_n^* + A_n^* + D_n^* \right) \cos n\theta + \frac{\gamma_D^u}{\gamma} \left(\frac{\gamma}{V} \right) + 1 \right] \quad (17)$$

Expanding both sides of equation (17) into Fourier cosine series and equating each of the six harmonics results in six linear algebraic equations in terms of the six unknowns, C_n . With the parameter e defined below,

$$e \equiv \frac{c}{4D} \quad (18)$$

the equation for the zeroth harmonic is

$$\begin{aligned} & \left[(1 - P_{00}) - 2R_0^* e \left(\ln \frac{4}{e} - 1 \right) - R_1^* e \right] C_0 \\ & + \left[\frac{R_2^* e}{4} - R_0^* e \left(\ln \frac{4}{e} - 1 \right) \right] C_1 + \left[\frac{R_3^* e}{6} - \frac{R_1^* e}{2} - P_{02} \right] C_2 \\ & + \left[\frac{-R_2^* e}{4} \right] C_3 + \left[-\frac{R_3^* e}{6} - P_{04} \right] C_4 + \left[0 \right] C_5 \\ & = 2R_0^* B_0^* + R_1^* B_1^* + R_2^* B_2^* + R_3^* B_3^* - 2B_0 \\ & + \frac{V}{\gamma} \left[2R_0^* (D_0^* + A_0^* + 1) + R_1^* (D_1^* + A_1^*) + R_2^* (D_2^* + A_2^*) \right. \\ & \left. + R_3^* (D_3^* + A_3^*) - 2(D_0 + A_0) \right] \quad (19) \end{aligned}$$

The equation for the first harmonic is

$$\begin{aligned}
& \left[P_{10} - 2R_0^*e - 2R_1^*e \left(\ln \frac{4}{e} - 1 \right) - R_2^*e \right] C_0 \\
& + \left[(P_{11} - 1) - R_1^*e \left(\ln \frac{4}{e} - 1 \right) + \frac{R_1^*e}{4} + \frac{R_3^*e}{4} \right] C_1 \\
& + \left[-R_0^*e - \frac{R_2^*e}{3} \right] C_2 + \left[P_{13} - \frac{R_1^*e}{4} - \frac{R_3^*e}{8} \right] C_3 \\
& + \left[-\frac{R_2^*e}{6} \right] C_4 + \left[P_{15} - \frac{R_3^*e}{8} \right] C_5 \\
& = 2R_0^*B_1^* + 2R_1^*B_0^* + R_1^*B_2^* + R_2^*(B_1^* + B_3^*) + R_3^*(B_2^* + B_4^*) - 2B_1 \\
& + \frac{V}{\gamma} \left[2R_0^*(D_1^* + A_1^*) + 2R_1^*(D_0^* + A_0^* + 1) + R_1^*(D_2^* + A_2^*) \right. \\
& + R_2^*(D_1^* + D_3^* + A_1^* + A_3^*) + R_3^*(D_2^* + D_4^* + A_2^* + A_4^*) \\
& \left. - 2(D_1 + A_1) \right] \tag{20}
\end{aligned}$$

The equation for the second harmonic is

$$\begin{aligned}
& \left[P_{20} - e(R_1^* + R_3^*) - 2R_2^*e \left(\ln \frac{4}{e} - 1 \right) \right] C_0 \\
& + \left[\frac{R_0^*e}{2} - R_2^*e \left(\ln \frac{4}{e} - 1 \right) \right] C_1 + \left[(P_{22} - 1) - \frac{R_1^*e}{3} - \frac{R_3^*e}{2} \right] C_2 \\
& + \left[\frac{R_2^*e}{8} - \frac{R_0^*e}{2} \right] C_3 + \left[P_{24} - \frac{R_1^*e}{6} + \frac{R_3^*e}{10} \right] C_4 + \left[-\frac{R_2^*e}{8} \right] C_5 \\
& = 2R_0^*B_2^* + R_1^*(B_1^* + B_3^*) + R_2^*(2B_0^* + B_4^*) + R_3^*(B_1^* + B_5^*) - 2B_2 \\
& + \frac{V}{\gamma} \left[2R_0^*(D_2^* + A_2^*) + (R_1^* + R_3^*)(D_1^* + A_1^*) + R_1^*(D_3^* + A_3^*) \right. \\
& \left. + 2R_2^*(D_0^* + A_0^* + 1) + R_2^*(D_4^* + A_4^*) + R_3^*(D_5^* + A_5^*) - 2(D_2 + A_2) \right] \tag{21}
\end{aligned}$$

The equation for the third harmonic is

$$\begin{aligned}
& \left[P_{30} - R_2^* e - 2R_3^* e \left(\ln \frac{4}{e} - 1 \right) \right] C_0 \\
& + \left[P_{31} + \frac{R_1^* e}{4} - R_3^* e \left(\ln \frac{4}{e} - 1 \right) \right] C_1 + \left[\frac{R_0^* e}{3} - \frac{R_2^* e}{2} \right] C_2 \\
& + \left[(P_{33} - 1) - \frac{R_1^* e}{8} \right] C_3 + \left[\frac{R_2^* e}{10} - \frac{R_0^* e}{3} \right] C_4 + \left[P_{35} - \frac{R_1^* e}{8} \right] C_5 \\
& = 2R_0^* B_3^* + R_1^* (B_2^* + B_4^*) + R_2^* (B_1^* + B_5^*) + 2R_3^* B_0^* - 2B_3 \\
& + \frac{V}{\gamma} \left[2R_0^* (D_3^* + A_3^*) + R_1^* (D_2^* + A_2^* + D_4^* + A_4^*) \right. \\
& \left. + R_2^* (D_1^* + A_1^* + D_5^* + A_5^*) + 2R_3^* (D_0^* + A_0^* + 1) - 2(D_3 + A_3) \right]
\end{aligned} \tag{22}$$

The equation for the fourth harmonic is

$$\begin{aligned}
& \left[P_{40} - R_3^* e \right] C_0 + \left[\frac{R_2^* e}{4} \right] C_1 + \left[P_{42} + \frac{R_1^* e}{6} - \frac{R_3^* e}{2} \right] C_2 \\
& + \left[\frac{R_0^* e}{4} - \frac{R_2^* e}{4} \right] C_3 + \left[(P_{44} - 1) - \frac{R_1^* e}{15} \right] C_4 + \left[-\frac{R_0^* e}{4} \right] C_5 \\
& = 2R_0^* B_4^* + R_1^* (B_3^* + B_5^*) + R_2^* B_2^* + R_3^* B_1^* - 2B_4 \\
& + \frac{V}{\gamma} \left[2R_0^* (D_4^* + A_4^*) + R_1^* (D_3^* + A_3^* + D_5^* + A_5^*) \right. \\
& \left. + R_2^* (D_2^* + A_2^*) + R_3^* (D_1^* + A_1^*) - 2(D_4 + A_4) \right]
\end{aligned} \tag{23}$$

The equation for the fifth harmonic is

$$\begin{aligned}
& \left[P_{50} \right] C_0 + \left[P_{51} + \frac{R_3^* e}{4} \right] C_1 + \left[\frac{R_2^* e}{6} \right] C_2 + \left[P_{53} + \frac{R_1^* e}{8} - \frac{R_3^* e}{4} \right] C_3 \\
& + \left[\frac{R_0^* e}{5} - \frac{R_2^* e}{6} \right] C_4 + \left[(P_{55} - 1) - \frac{R_1^* e}{8} \right] C_5 \\
& = 2R_0^* B_5^* + R_1^* B_4^* + R_2^* B_3^* + R_3^* B_2^* - 2B_5 + \frac{V}{\gamma} \left[2R_0^* (D_5^* + A_5^*) \right. \\
& \quad \left. + R_1^* (D_4^* + A_4^*) + R_2^* (D_3^* + A_3^*) + R_3^* (D_2^* + A_2^*) - 2(D_5 + A_5) \right]
\end{aligned} \tag{24}$$

Solution of equations (19) through (24) yields the C_n coefficients defining the duct-bound vorticity, which in turn permit a new inflow profile to be computed from equation (5).

2.2 Angle of Attack

The angle of attack solution is that for a thin, cylindrical duct in a crossflow $V \sin \alpha$. This solution is superimposed on the axial flow solution as follows. The ducted fan is considered to be in a modified axial flow in which the velocity \bar{V} is $V \cos \alpha$. The axial flow analysis discussed in section 2.1 is applied to obtain the axisymmetric portion of the bound and free vorticity and source distributions. The duct is then considered to be in a flow at angle of attack. A nonaxisymmetric vorticity distribution is placed on the duct to cancel the $V \sin \alpha$ crossflow through the duct reference cylinder. The duct-bound vorticity has the form

$$\frac{\gamma_\alpha}{V} = \sin \alpha \cos \phi \left[c_0 \cot \frac{\theta}{2} + \sum_{n=1}^5 c_n \sin n\theta \right] \tag{25}$$

where the c_n coefficients are functions only of c/D and are tabulated in Table I of reference 10. There is in addition a distribution of free trailing filaments caused by the variation of strength around the γ_α rings. The forces and moments on the ducted fan are then computed by considering both the axisymmetric and nonaxisymmetric singularity distributions.

The $V \sin \alpha$ crossflow and the γ_α vorticity induce a nonaxisymmetric inflow into the fan. The resulting circumferentially varying blade loading was examined in reference 5. A solution was obtained, with a number of simplifying assumptions, that indicated two compensating effects occurring to cause the net effect of angle of attack on blade load distribution to be relatively small. On the basis of these results and the complexity of the analysis, the inclusion of angle of attack effects on fan loading in the computer program was not considered justified.

The force and moment equations are derived in references 1 and 5 by considering the force resulting from a velocity acting on a bound vorticity. The viscous drag on the duct, centerbody, and fan blades is not considered in the analysis. The forces and moments on the centerbody and the moment on the fan are small compared to the duct loading and are neglected.

The effective free stream is defined by the variables

$$\begin{aligned}\bar{J}' &= J' \cos \alpha \\ \bar{V} &= V \cos \alpha\end{aligned}\tag{26}$$

Thus, the fan thrust coefficient² is given by equation (10) of reference 5 as

$$C_{T_{P(D)}} = \frac{A_p}{A} \frac{N}{\pi \bar{J}' z} \sum_{n=1}^z \frac{\Gamma_n}{R \bar{V}} \cos^2 \alpha\tag{27}$$

The duct thrust coefficient due to the duct singularity distribution is computed using equation (36) of reference 1.

²The equations for the force and moment coefficients given in this section are based on nondimensionalizing the force or moment by q , A , and R . The alternate approach noted in the Symbols List is also provided within the program.

$$c_{T_D(P)} = -\pi \frac{c}{D} \frac{\gamma}{V} \cos^2 \alpha \left[c_0 (4E_0 + 2E_1) + 2c_1 E_0 + \sum_{n=1}^4 (c_{n+1} E_n - c_n E_{n+1}) \right] \quad (28)$$

where

$$E_n = \frac{\gamma}{V} B_n + A_n + D_n \quad (29)$$

In the assumed flow model, there is a discontinuity in the duct surface pressure distribution due to the pressure rise across the fan. The increased pressure acting on the inner duct surface aft of the fan causes the following duct thrust coefficient.

$$c_{T_D(P)} = \left[1 - \left(\frac{R_p}{R} \right)^2 \right] \frac{\Delta p_z}{q} \cos^2 \alpha \quad (30)$$

One component of the thrust coefficient due to the duct at angle of attack is

$$c_{T_D(\alpha)} = \pi \frac{c}{D} \sin^2 \alpha (2c_0 + c_1) \quad (31)$$

from equation (39) of reference 1. The second part of the thrust coefficient due to the duct at angle of attack is

$$c_{T_D(\alpha)} = -\frac{\pi}{2} \frac{c}{D} \sin^2 \alpha \left[c_0 (4H_0 + 2H_1) + 2c_1 H_0 + \sum_{n=1}^4 (c_{n+1} H_n - c_n H_{n+1}) \right] \quad (32)$$

from equation (41) of reference 1. The H_n Fourier series coefficients describe the radial velocity distribution induced at the duct by the trailing vortex filaments associated with γ_α . These Fourier coefficients are defined in equation (40) of the above reference. The total duct thrust coefficient is then the sum of equations (27), (28), (31), and (32).

The duct normal force coefficient is given by equations (48), (51), and (52) of reference 1.

$$C_{N_{DP}} = \frac{\pi C}{2 D} \sin \alpha \cos \alpha \left[(4c_0 + 2c_1) + f(c_n, E_n^*) + g(c_n, G_n^*) \right] \quad (33)$$

where

$$E_n^* = \frac{\gamma}{V} (B_n^* + F_n^*) + A_n^* + D_n^* \quad (34)$$

and

$$f(c_n, E_n^*) = c_0 (4E_0^* + 2E_1^*) + 2c_1 E_0^* + \sum_{n=1}^4 (c_{n+1} E_n^* - c_n E_{n+1}^*) \quad (35)$$

$$g(c_n, G_n^*) = c_0 (4G_0^* + 2G_1^*) + 2c_1 G_0^* + \sum_{n=1}^4 (c_{n+1} G_n^* - c_n G_{n+1}^*) \quad (36)$$

The G_n^* are the Fourier coefficients describing the velocity u_{γ_D} which is computed using equation (49) of reference 1.

$$\frac{u_{\gamma_D}}{V} = \sin \alpha \cos \phi \sum_0^5 G_n^* \cos n\theta \quad (37)$$

The F_n^* are the Fourier coefficients describing the velocity u_{γ_D} which is computed using equation (A-9) of reference 5.

$$\frac{u_{\gamma_D}}{\gamma} = \sum_0^5 F_n^* \cos n\theta \quad (38)$$

The duct pitching moment coefficient is given by equations (57), (59), (60), and (62) of reference 1 as

$$\begin{aligned}
c_{M_{DP}} = & \frac{\pi}{2} \sin \alpha \cos \alpha \left\{ \frac{1}{2} \frac{\gamma}{V} \left(\frac{C}{D}\right)^2 \bar{f}(c_n, G_n^*) + \left(\frac{C}{D}\right)^2 (2c_0 + c_2) \right. \\
& + \frac{1}{2} \left(\frac{C}{D}\right)^2 \bar{g}(c_n, E_n^*) - \frac{C}{D} \left[c_0 (4E_0' + 2E_1') + 2c_1 E_0' \right. \\
& \left. \left. + \sum_{n=1}^4 (c_{n+1} E_n' - c_n E_{n+1}') \right] \right\} \quad (39)
\end{aligned}$$

where

$$E_n' = \frac{\gamma}{V} (B_n + F_n) + A_n + D_n \quad (40)$$

$$\begin{aligned}
\bar{f}(c_n, G_n^*) = & c_0 (4G_0^* + 4G_1^* + 2G_2^*) + c_1 (G_1^* - G_3^*) + c_2 (2G_0^* - G_4^*) \\
& + c_3 (G_1^* - G_5^*) + c_4 G_2^* + c_5 G_3 \quad (41)
\end{aligned}$$

$$\begin{aligned}
\bar{g}(c_n, E_n^*) = & c_0 (4E_0^* + 4E_1^* + 2E_2^*) + c_1 (E_1^* - E_3^*) + c_2 (2E_0^* - E_4^*) \\
& + c_3 (E_1^* - E_5^*) + c_4 E_2^* + c_5 E_3 \quad (42)
\end{aligned}$$

The F_n are the Fourier coefficients describing the velocity v_{γ_D} which is computed using equation (16).

$$\frac{v_{\gamma_D}}{\gamma} = \sum_0^5 F_n \cos n\theta \quad (43)$$

The duct surface pressure distribution is obtained from the Bernoulli equation

$$c_p = 1 - \left(\frac{u_s}{V}\right)^2 \quad (44)$$

where u_s is the induced surface velocity distribution. The surface velocity, u_s , is made up of a continuous portion and a discontinuous portion as given by equation (67) of reference 1. The continuous

velocity is corrected for duct thickness and the discontinuous velocity is approximated near the leading edge to remove the singularity. These corrections and approximations are explained in detail in reference 1.

3. PROGRAM DESCRIPTION

3.1 Calculation Procedure

The computation proceeds as follows. An initial knowledge of the fan inflow velocity profile is required to compute blade performance, from which all other computations are made. Since the inflow is affected by the as yet undetermined duct-bound vorticity, an iterative procedure is used. An initial, uniform inflow of $2V$ is assumed, and the blade element calculations are made to determine the fan performance and the fan wake characteristics. The flow tangency condition on the duct reference cylinder is then applied to determine the duct-bound vorticity distribution. With all the singularity distributions known, the fan inflow is calculated. This is compared with the initially assumed inflow. If the two do not agree, a new inflow equal to the average between the initial and computed inflows is determined. The fan and duct-bound vorticity calculations are repeated to obtain a new inflow. The process continues until the inflow velocity in each annulus has converged to within the desired value. When convergence is obtained for all annuli, the program continues to calculate force and moment coefficients and duct surface pressure coefficients if desired.

3.2 Flow of Calculations

This section contains a discussion of the sequence of calculations within the program. The discussion describes the functions that are performed in the main program and each of the subroutines and the basic order in which they are performed. References are given for the various equations or relations used in the parts of the program.

The program consists of a main program and 20 subroutines. The cards in the source deck are identified in Columns 73 to 80 with a four-character identification indicating the number of the subroutine and a three-digit number representing the order of the card within the subroutine.

The main program is relatively short. Its basic functions are to control the flow of the program, and to perform the calculation for the local blade element performance, the calculation for the total fan inflow, the comparison of initial and computed inflows to determine convergence, and the calculation of the new inflow profile if the solution is not converged. The relationship between the main program and the subroutines is shown in figure 3.

The first operation in MAIN is a general initialization of four subroutines. ELLIPS is called to initialize tables of elliptic integrals, LAMBDA is called to initialize tables of the Heuman Lambda Function, PKL is called to initialize tables of $P_{k\ell}$ coefficients at various ratios of duct chord to diameter, and CLALF is called to initialize a table of section $c_{\ell_{\max}}$ versus thickness-to-chord ratio. The table of $c_{\ell_{\max}}$ versus t/c is determined from figure 2(b) of reference 1.

The program has several subroutines which are necessary for the operation of the program because of the service they perform, but they are not important to the understanding of the sequence of events in the program. These will be discussed here briefly and then omitted from the following program description, although they are shown on figure 3. Subroutine ELLIPS does a table look-up for the complete elliptic integrals of the first and second kind, given the argument of the elliptic integrals. Subroutine LAMBDA does a table look-up for the Heuman Lambda Function, given the two arguments of the function. Subroutine ARCSIN computes the principal value of the angle given the value of the sine of the angle. Subroutine FOURCS does a Fourier analysis of a function, given a table of values of the function. The subroutine computes an n -term cosine series ($n \leq 50$) to fit the given function. The first six terms of the series are used for the calculations in the program.

Subroutine INPUT is called by the main program. The major function of subroutine INPUT is to determine all of the quantities used in the calculation that are functions only of the duct configuration, the centerbody geometry, the fan blade characteristics, or the number of fan annuli. Included in these quantities are the Fourier series coefficients for velocities and vorticities which are functions only of duct chord-to-diameter ratio or duct thickness. This subroutine also

reads in the input data, checks it for certain specific errors, and then prints out all of the input information. Now several subroutines must be called to do more specific initialization of parameters which are only dependent on the geometry of the system. Subroutine HUB is called to compute the strength and location of the point source and point sink which describe the centerbody model. ALFRNG is called to compute the G_n^* Fourier coefficients in equation (37) and the H_n Fourier coefficients in equation (32). PRESS is called to set up tables of the duct thickness correction factor and the leading-edge singularity parameter. These tables are used in the calculation of the duct surface pressure distribution. Subroutine INPUT next calls subroutine PKL to look up a table of the $P_{k\ell}$ influence coefficients. These coefficients, used in computing the radial velocity induced by a distribution of vortex rings, are functions only of c/D and are obtained from reference 9. Subroutine CAMBER is called to compute the induced camber coefficients which are combined with the geometric camber coefficients to obtain the total effective camber of the duct.

Subroutine HUB is called again by INPUT to compute the Fourier coefficients D_n and D_n^* . These coefficients are constants for a given duct and centerbody configuration; therefore, they may be computed at this time assuming a unit free stream and then correcting for the increased free stream as they are used.

Subroutine PROP divides the fan annulus into the required number of annuli (which is input), computes the inner, outer, and mean radii of the annuli and interpolates in the blade β , b/R_p , and h/b input tables to obtain values of β , b/R_p , and h/b at the mean radii of the annuli.

Certain components of the inflow to the fan are constants and can be computed at this time. Subroutine GAMCYL computes the nondimensional axial inflow velocities (in the form u/γ) induced at the mean radii of the fan annuli by a vortex cylinder trailing from the duct trailing edge. These are a function only of c/D . The equation solved is equation (A-10) of reference 5. In this equation, it is necessary to use elliptic integrals, an arcsin relation, and the Heuman Lambda Function. These are obtained, respectively, from subroutines ELLIPS, ARCSIN, and LAMBDA. Subroutine SRCRNG computes the nondimensional axial inflow velocity

(in the form u/V) induced at the mean radii of the fan annuli by the source rings representing the duct thickness distribution. The equation used is equation (A-6) of reference 5. Subroutine HUB computes the nondimensional axial inflow velocity (in the form u/V) induced at the mean radii of the fan annuli by the source-sink distribution representing the centerbody geometry. The equation used is equation (15) of reference 1. The two latter inflow velocities must be corrected for the increased local axial velocity as is discussed in reference 1.

Subroutine BNCOEF computes the Fourier cosine series coefficients (B_n) for the nondimensional radial velocity (in the form v/γ) induced along the duct reference cylinder by a vortex cylinder trailing from the duct trailing edge. The equation used is equation (C-3) of reference 5. The subroutine ANCOEF computes Fourier series coefficients for three sets of velocities on the duct reference cylinder. The coefficients B_n^* are those of the nondimensional axial velocity (u/γ) induced by a vortex cylinder from the duct trailing edge (eqs. (23) and (25) of ref. 3). The coefficients (A_n)_w and (A_n^*)_w are those of the nondimensional radial (v/γ_w) and axial (u/γ_w) velocities, respectively, induced by the w^{th} inner vortex cylinder trailing from the fan. The equations used are equations (13) and (16), and equations (20) and (21), respectively, of reference 3. These Fourier coefficients are obtained by fitting a 50-term Fourier cosine series to the chordwise velocity distribution and truncating after the sixth term. At this point, the coefficients for all of the velocities induced at the duct reference cylinder by the fan wake, duct thickness, and the centerbody are known, and control returns to the main program.

The blade element performance in each of the fan disk annuli is computed using the local blade lift coefficient obtained from subroutine CLALF. The section c_ℓ includes the effect of local blade stall in the manner described in reference 1. The strengths of the internal vortex cylinders are now computed. The main program calls subroutine CNCOEF. The basic purpose of this subroutine is to apply the boundary condition of no flow through the duct camberline to compute the Fourier coefficients, C_n , representing the duct-bound vorticity γ_D . The six C_n coefficients are obtained from the solution of a matrix equation involving the A_n , A_n^* , B_n , B_n^* , D_n , D_n^* coefficients, the camber

coefficients, and the vortex cylinder strengths just computed. The three dependent matrices in this equation are computed and defined in subroutine CNCOEF. The equation is then solved for the C_n through use of the matrix inversion subroutine, MATRIX. If the matrix to be inverted is singular, an error message is printed and the subroutine transfers to a STOP statement.

Now that all the singularity distributions are known, the correction factors which are applied to the duct thickness-induced velocities and the centerbody-induced velocities are computed. Both correction factors need the velocities induced by the vortex cylinder trailing from the trailing edge of the duct and the duct-bound vorticity, γ_D . These induced axial velocities are obtained from subroutines GAMCYL and VTXRNG, respectively.

Subroutine VTXRNG is called again to compute the axial inflow to the fan due to the duct-bound vorticity, γ_D . Equation (A-9) of reference 5 is used with the C_n coefficients just computed.

The main program then sums the inflow velocities in each of the fan annuli obtained from all the singularity distributions and adds to these the free-stream velocity and the discontinuous portion of the velocity difference across each vortex cylinder ($\gamma_w/2$). The resulting total inflow in each annulus is compared with the initially assumed inflow. If all velocities do not agree within the prescribed convergence limit, the new inflow is assumed to be the average between the initial and computed velocities. The program then returns to the computation of new values of the local blade performance. Subroutine CNCOEF is called, new C_n coefficients determined, new corrections for the centerbody-induced velocities and duct-thickness-induced velocities are computed, VTXRNG is called to obtain the fan inflow due to the duct-bound vorticity, and a new total fan inflow obtained. This iterative process is repeated until convergence is obtained for all the fan annuli or until 50 iterations have been completed.

After convergence is obtained, the main program calls OUTPUT which immediately prints out the fan loading and inflow parameters. The force and moment coefficients are computed and output, and if the duct surface pressure coefficients are to be computed, subroutine PRESS is called. In PRESS, the velocity induced on the duct reference cylinder by all the

singularity distributions is computed. This includes the axial velocity induced by the duct-bound vorticity, γ_α , associated with the duct at angle of attack. These induced velocities are obtained from subroutine ALFRNG which uses equation (49) of reference 1. After summing all the continuous and discontinuous velocity components, Bernoulli's equation is used to compute the duct surface pressure coefficients. Control returns to OUTPUT where the pressure coefficients are printed. This completes the series of calculations and control is returned to the main program.

The above sequence of operations is arranged such that the calculations performed by INPUT provide all the parameters dependent only on the duct and propeller configuration. Thus, if performance of a given configuration at a number of advance ratios or angles of attack is desired, an index is read from a card following completion of the calculations in OUTPUT, the next values of J and α read, and control is returned to the part of the main program just after INPUT has been called, which avoids some recomputation. If a new configuration is to be analyzed, control returns to the statement in the main program calling INPUT, where a complete new case is read in.

3.3 Use of Program

The program is written in Fortran IV for the IBM 7094 computer. No tapes other than the standard input and output tapes are required. Typical execution times are approximately two minutes for the first case and one minute for each additional run utilizing the same geometry. A complete description of the input and output is presented in sections 4 and 5 respectively, and a program listing is given in section 7.

4. DESCRIPTION OF INPUT

This section contains a description of the input for the computer program. The information required on the cards is described in section 4.1. The remainder of the subsections below describe the manner in which some of the input quantities are determined for a given ducted fan configuration.

4.1 Input Data

The format of the input cards making up a normal run is shown in figure 4. In this figure the variable is given as well as the card column in which the punching of the value of the variable is begun and the format in which it is punched. In all input the format is set up for four figures to the right of the decimal point. If more significant figures are required, the decimal point may be moved to the left some appropriate amount. As long as the number is punched in the specified field of 10 columns, the decimal point may be punched in any column.

Card No. 1 contains any alphabetic and numeric information that is desired for identification purposes. This information is printed at the top of each page of output.

Card No. 2 contains information about the geometry of the duct. The first item (c/D) is the chord-to-diameter ratio. This value should be greater than zero and less than about 2.5. This upper limit is approximate and is necessary only because some coefficients built into the program must be extrapolated for $c/D > 2$. The next items on this card are the axial location of the fan within the duct (x_p/c), the maximum thickness-to-chord ratio of the airfoil section of the duct (t/c),³ the ratio of the duct radius at the trailing edge to the fan radius (R/R_p), and the ratio of the centerbody radius at the fan station to the fan tip radius (R_{CB}/R_p) (or the fan hub-tip ratio). The last item is the convergence criterion (ϵ). The iteration will stop when the inflow profiles agree within $\epsilon \times 10^2$ percent. A suggested range for ϵ is $0.001 \leq \epsilon \leq 0.01$.

Card No. 3 contains the four Fourier coefficients (R_n) of a cosine series fit to the duct camberline. If the duct is uncambered, these four values are all zero.⁴

³The value of t/c must be within the range $0.06 \leq t/c \leq 0.24$ because of correction factors used in the calculation of duct pressure distribution. If t/c is outside this range, the pressure distribution will be slightly in error, but all other calculations will be correct.

⁴A detailed discussion of the manner of computing these four coefficients is given in section 4.2.

Card No. 4 contains the information necessary to define the centerbody. The first item is the centerbody length expressed as a fraction of the duct chord (ℓ_{CB}/c). The second item is the location of the centerbody nose in the duct coordinate system (x_{CB}/c). If the centerbody extends forward of the duct leading edge, $x_{CB}/c < 0$. The next item is the maximum radius of the centerbody expressed as a fraction of the centerbody length (r_{max}/ℓ_{CB}) and the last item on this card is the x location of r_{max} ($x_{r_{max}}$) in the duct coordinate system. Preparation of the input on this card must meet certain specifications which are discussed in detail in section 4.3.

Card No. 5 contains six quantities. The first, NBLD, is the number of fan blades. This number must be greater than zero. The second item, NZ, is the number of equal area annuli into which the fan annulus is divided. The limitation on NZ is $2 \leq NZ \leq 24$. The third item, NZP, is the number of stations in the input table of fan blade characteristics. The limitations on NZP are $2 \leq NZP \leq 24$. The next quantity is IR, the number of x-stations at which the duct surface pressure distribution is to be calculated. At a given x/c , the pressure coefficient is computed on the inside and outside surface of the duct. The value of IR must be in the range $1 \leq IR \leq 25$.⁵ The next item, NPRES, is an index which controls the form of the surface pressure coefficient. If NPRES = 1, the surface pressure coefficient is based on free-stream dynamic pressure. If NPRES = 2, the surface pressure coefficient is based on the propeller tip speed. The last quantity, NPRINT, is an output index which controls the quantity of output. For normal runs, NPRINT = 0. If NPRINT = 1, an extra page of optional output is developed which contains a table of the components of the inflow to the propeller. This optional output is described in the output section of this report. Another output option is available, but the authors recommend that it not be used, as it is useful only for diagnostic purposes. If NPRINT = 10, a page listing all of the Fourier cosine series coefficients for the u and v

⁵The input controlling the pressure distribution calculation has been set up for ease of repetitive running with the same configuration. Consequently, IR must be 1 or greater, whether or not any pressures are to be computed. An index on the last card indicates the requirement for computing pressures.

velocities induced at the duct reference cylinder is printed. If $NPRINT = 11$, both of the above optional pages are output. In most cases of interest, $NPRINT$ will be identically zero.

Card No. 6 contains the fan radii (r/R_p) at which the blade characteristics are to be input. There are NZP entries in this table, so if $NZP > 8$, the other entries in the table must be included on following cards. For example, if $NZP = 17$, three cards are required. The first two cards will have eight fields each and the third card one field. The values must be put in order of increasing radius ratio. The first entry in the table should be the value of r/R_p at the root or hub, which nominally is equal to R_{CB}/R_p , the value on Card No. 2. The last value in the table should be $r/R_p \approx 1.0$. There cannot be more than 24 entries in the table.

Card No. 7 contains values of the fan blade chord (b/R_p) at the radial stations corresponding to the values on Card No. 6. With eight fields per card, there will be as many cards here as in the r/R_p case (Card No. 6).

Card No. 8 contains the fan blade pitch angle (β) in degrees at the radial stations corresponding to the values on Card No. 6. The pitch angle is the blade twist angle measured from the plane of rotation to the zero lift line of the local blade section. The number of cards here will be the same as the number of r/R_p cards (Card No. 6).

Card No. 9 contains the blade section thickness-to-chord ratio at the radial stations corresponding to those on Card No. 6. The number of cards here will be the same as the number of r/R_p cards (Card No. 6).

Card No. 10 contains the values of x/c at which the duct surface pressure coefficients are to be calculated. This card should contain IR values, and if $IR > 8$, the ninth and succeeding values should be put on following cards in the same format as shown for Card No. 10. The values should be put in ascending order with the limitation $0 \leq x/c \leq 1.0$. Since the inner duct surface pressure distribution has a discontinuity at the fan due to the pressure jump aft of the fan, it is desirable to include x/c values just upstream and downstream of the fan. No numerical problem occurs, however, if the x/c value exactly at the fan station is input, since the program uses the total

pressure upstream of the fan to compute the inner duct pressure coefficient at the fan station.

Card No. 11 is the last card required for a particular configuration. The first item on this card is a run identification number, NRUN. The only restrictions on NRUN are that $NRUN \leq 9999$ and $NRUN \neq 0$. The second quantity is the index NPFI, which is the number of azimuth stations around the duct at which the surface pressure coefficients are to be calculated. The limitation is that $0 \leq NPFI \leq 5$. If $NPFI = 0$, no pressure calculation will be performed for this run. The next quantity is the advance ratio, J. The advance ratio must be greater than zero.⁶ The duct angle of attack, α , in degrees is the next item. The only requirement is that $\cos \alpha \neq 0$. The remaining five fields on the card should contain the azimuth angles, ϕ , in degrees, at which pressure distributions are to be calculated. There should be NPFI values of ϕ , and due to the symmetry of the flow, $0 \leq \phi \leq 180^\circ$.

If only one run is to be made, the input deck is complete with Card No. 11. If two or more runs are to be made, the card arrangement following Card No. 11 for stacking runs is as follows:

(1) If the same ducted fan configuration is to be investigated at a different advance ratio or angle of attack or if different values of ϕ are of interest, only one additional card is required to initiate the new run. This card has the same format as Card No. 11. The run number can be changed to identify the new run. Each succeeding run with the same configuration requires the one additional card, and this card can be repeated as many times as desired.

(2) If a different duct and/or fan configuration is to be investigated, the card following Card No. 11 must be blank. The new case is then loaded as a deck consisting of Card Nos. 1 through 11.

A sample set of input data illustrating the program options is shown in figure 6.

⁶A value of $J = 0$ causes numerical problems in the machine. To compute a zero advance ratio (hover) case, set $J = 0.01$.

4.2 Duct Camber and Thickness

The duct thickness and camber are required on the second and third cards. A brief discussion is given below with regard to the selection of these parameters. In order to give a reasonably wide latitude to the use of the program while at the same time not storing a great quantity of airfoil data in the program, the specifications of duct thickness and camber were separated.

The thickness distribution is taken to be the local profile thickness as measured from the camberline. For purposes of including thickness effects in the performance calculations, the thickness distribution is specified within the program as that of a symmetrical four-digit NACA airfoil which has an analytical expression for the variation of thickness with distance along the chord. This distribution is completely specified by one parameter, the ratio of maximum thickness to chord. In selecting a value for a given duct configuration, it is suggested that the $(t/c)_{\max}$ value be chosen which will yield the best fit to the actual duct shape along the inner forward portion of the duct, while still giving a reasonable fit over the other portions of the section. Tables of thickness distribution for various $(t/c)_{\max}$ can be obtained from Appendix I of reference 11.

The camber coefficients required in the third card are computed according to the methods given below. Figure 1 indicates the notation and coordinate systems. The axial coordinates are x , measured from the leading edge with the range 0 to c ; θ , measured from the leading edge with the range 0 to π ; and x_s , measured from $x = c/2$ with the range $-c/2$ to $+c/2$. The relation between θ and x_s is given by

$$\cos \theta = -2x_s/c \quad (45)$$

The local slope of the geometric camberline is

$$\frac{dr_c}{dx_s} = \sum_{n=0}^3 R_n \cos(n\theta) \quad (46)$$

This can be integrated to give the camberline shape as

$$\begin{aligned} \frac{r_c - R}{c} = & -R_0 \left(\frac{1 + \cos \theta}{2} \right) + R_1 \left(\frac{1 - \cos^2 \theta}{4} \right) \\ & + R_2 \left(\frac{1}{6} + \frac{1}{2} \cos \theta - \frac{1}{3} \cos^3 \theta \right) \\ & + R_3 \left(-\frac{1}{4} + \frac{3}{4} \cos^2 \theta - \frac{1}{2} \cos^4 \theta \right) \end{aligned} \quad (47)$$

The camberline radius at the trailing edge is identically that of the duct reference cylinder, which passes through the trailing-edge radius; that is, at $\theta = \pi$, $r_c - R = 0$. Four other points along the camberline must be selected and their r_c values put into the above equation to obtain four simultaneous equations for the four R_n coefficients. It is suggested on the basis of past experience that these points be nearly equally spaced for best results; that is, at $x/c = 0, 1/4, 1/2$, and $3/4$. If these four points are chosen, the R_n coefficients can be calculated from the following equations.

$$\begin{bmatrix} R_0 \\ R_1 \\ R_2 \\ R_3 \end{bmatrix} = \begin{bmatrix} (-1 \frac{2}{3}) & (1 \frac{1}{3}) & (0) & (-1 \frac{1}{3}) \\ (-3 \frac{1}{3}) & (5 \frac{1}{3}) & (-4) & (5 \frac{1}{3}) \\ (-2) & (4) & (0) & (-4) \\ (-1 \frac{1}{3}) & (5 \frac{1}{3}) & (-8) & (5 \frac{1}{3}) \end{bmatrix} \times \begin{bmatrix} \left(\frac{r_c - R}{c} \right)_0 \\ \left(\frac{r_c - R}{c} \right)_{1/4} \\ \left(\frac{r_c - R}{c} \right)_{1/2} \\ \left(\frac{r_c - R}{c} \right)_{3/4} \end{bmatrix} \quad (48)$$

If the camberline is not well behaved (for example, if it should have a hook near the leading edge), four other values of x/c may be necessary to give the best overall fit to the actual camberline. Several tries may be necessary to select the right combination of four points.

If the duct has no camber, all the R_n coefficients are input equal to zero.

4.3 Centerbody

The centerbody shape is approximated by a Rankine body, figure 5. Because the centerbody model is so simple, there are certain restrictions on the input. It is necessary that x_{CB}/c , r_{max}/l_{CB} , l_{CB}/c , and $x_{r_{max}}/c$ be input such that the centerbody half-length (distance between the nose and the point of maximum radius) is greater than the maximum radius; that is

$$x_{r_{max}} - x_{CB} > r_{max}$$

or in terms of the nondimensional ratios,

$$\left(\frac{x_{r_{max}}}{c}\right)\left(\frac{c}{l_{CB}}\right) - \left(\frac{x_{CB}}{c}\right)\left(\frac{c}{l_{CB}}\right) > \left(\frac{r_{max}}{l_{CB}}\right)$$

The effect of the centerbody on the ducted fan performance cannot be eliminated entirely from the program, but it can be made negligibly small by inputting the appropriate geometry. Thus, if the user wishes to remove the effect of the centerbody, the centerbody parameters should be input according to the following rules:

$$\frac{x_{CB}}{c} = \frac{x_p}{c} - 0.02$$

$$\frac{l_{CB}}{c} = 0.04$$

$$\frac{r_{max}}{l_{CB}} = 0.005$$

$$\frac{x_{r_{max}}}{c} = \frac{x_p}{c}$$

If these values are used, the area inside the fan hub radius (πR_{CB}^2) will be unloaded unless R_{CB} is set equal to zero. It should be noted that because of the formulation of the program, the leading edge of the centerbody should be forward of the fan station in order to avoid numerical problems; that is

$$\frac{x_{CB}}{c} < \frac{x_p}{c}$$

Generally, in approximating the centerbody shape, the user should try to fit the portion between the nose and the fan station best. This will give the best results for the inflow to the fan. If possible, the total length should be approximated, but if compromise is necessary, the portion ahead of the fan is more important than that aft of the fan. If the maximum centerbody radius occurs aft of the fan, some judgment must be used to decide on the position and value of the maximum radius. Remembering that the purpose of the centerbody model is to approximate the blockage effect on the inflow to the fan, the best centerbody model is a compromise to give the closest fit to both the maximum radius and the radius at the fan station.

4.4 Fan Blade Characteristics

A simple method to account for local blade stall is described in reference 1. This method involves a table of $c_{l_{max}}$ versus t/c derived from figure 2(b) of reference 1. This table is built into Subroutine CLALF. If the user wishes to change this table, he should use the following procedure.

The local section thickness-to-chord ratio is called array TCB with 10 entries ranging from $TCB(1) = 0$ to $TCB(10) = 0.34$. The blade section $c_{l_{max}}$ is called array CLMX, with 10 entries corresponding to the TCB array. The table is easily changed by changing corresponding entries of TCB and CLMX. It is advised that the total number of entries (10) in the table be unchanged. If the user would like to remove the effect of blade stall and assume that the blade section $c_{l_{\alpha}}$ is constant and equal to 2π at any angle of attack, every entry in the array CLMX should be set equal to some large number, for example, 10.0.

5. DESCRIPTION OF OUTPUT

The nominal output consists of three pages of data, to which can be added one additional page of optional output. The pages are numbered and each page has the run number at the top plus the identification information which is punched in the first card of the input deck.

A typical set of output including one page of optional output is shown in the sample case (figure 7).

The first page is numbered PAGE 0. It contains a listing of the input data plus a table of definitions of symbols. The input listed on the line entitled DUCT GEOMETRY is the duct chord-to-diameter ratio (C/D), the axial position of the fan station as a fraction of duct chord (XP/C), the duct maximum thickness-to-chord ratio (T/C), the ratio of the duct trailing-edge radius to fan radius (RTE/RP), and the ratio of centerbody radius in the plane of the fan to the fan radius (RCB/RP). The next line lists the geometric camber coefficients, R_n . The next group of data indicates the fan blade geometry input into the program. The number of blades is given, and a table of (nondimensional) blade chord (B/RP), blade pitch angle (BETA), and thickness-to-chord ratio (TH/CHD) versus nondimensional radius (R/RP) is given. This information is followed by the centerbody geometry which consists of the ratio of centerbody length to the duct chord (LCB/C), the axial location of the centerbody nose (XCB/C), the maximum radius of the centerbody in fraction of centerbody length (RMAX/LCB), and the axial location of the maximum radius (X(RMAX)/C). The next line contains the convergence criterion (EPSILON). This is followed by a table of symbols and their definitions.

Page 1 is optional output (NPRINT = 1) and is so noted at the top of the page. This page lists the inflow velocity results obtained after convergence of the iterative process. For convenience, the duct characteristics printed on the previous page are again printed here at the top of the page with the addition of the ratio of the fan disk area to the duct exit area (AP/A). The next line lists the four Fourier coefficients of the effective camber, R_n^* . Following these are the duct angle of attack in degrees (ALPHA), the advance ratios $J = V/nD_p$ and $J' = V/\omega R$, and the values of $J \cos \alpha$ and $J' \cos \alpha$. The following table lists the induced inflow velocity in each of the annuli (N). At the center of each of the annuli, denoted R/RP, the inflow is made up of the velocities induced by the duct thickness (UQD/V), the duct-bound vorticity (UGD/V), the vortex cylinder trailing from the fan tip (UG/V), and the centerbody (UCB/V). The final column indicates the local blade bound vorticity, Γ/RV , (GAMMA/RV). The numbers in parentheses above UQD/V and UCB/V are the correction factors for

the thickness distribution and the centerbody, respectively. The last output on the page is the number of iterations required for convergence, and the convergence criterion. When the duct is at angle of attack, the reference V in the table is actually $V \cos \alpha$ or \bar{V} .

The next page, page 2, lists the fan and duct performance. Again, the duct characteristics are listed at the top of the page, together with the angle of attack and advance ratios. The table that follows lists at each of the fan annuli centers (R/RP) the total inflow velocity (U/V), the strength of the vortex cylinder shed from the outer radius of the annulus (GAM/V), the angle of attack of the blade, in degrees, as measured from the line of zero lift of the blade, and the total pressure rise divided by the free-stream dynamic head ($\Delta P/Q$). When the duct is at angle of attack, the nondimensional inflow results, blade bound vorticity, and fan pressure rise are based on $\bar{V} = V \cos \alpha$, rather than V . Following the table are various force and moment coefficients preceded by note (A) or (B). The thrust and normal force and moment coefficients opposite (A) are defined as

$$C_T = \frac{T}{qA}$$

$$C_N = \frac{N}{qA}$$

$$C_M = \frac{M}{qAR}$$

where the moment center is at the center of the duct ($x = c/2, r = 0$). The coefficients opposite (B) are defined using the fan rotational speed and tip diameter as

$$C_T = \frac{T}{\rho n^2 D_p^4}$$

$$C_N = \frac{N}{\rho n^2 D_p^4}$$

$$C_M = \frac{M}{\rho n^2 D_p^5}$$

The propeller thrust coefficient is $CTP(D)$. The duct thrust coefficient based only on the thrust on the duct-bound singularity distributions is given as $CTD(P)$. The sum of these two is $CTDP$. The duct-thrust coefficient including the pressure thrust due to the fan tip pressure rise acting on the inner duct surface aft of the propeller as well as the thrust on the singularity distributions is noted $CTD(P)'$. The sum of this duct thrust and the propeller thrust is noted $CTDP'$. The normal-force coefficient is $CNDP$ and the moment coefficient is $CMDP$.

The thrust coefficients with and without the pressure thrust added to the inner duct surface are presented in the output. The results in reference 5 show that inclusion of the pressure thrust on the duct gives better agreement with measured duct-thrust coefficients and pressure distributions on the inner duct surface. Therefore, all thrust results presented in section 9, Data Comparisons, include the pressure thrust on the duct. Both thrust results are included in the output so that the user can see the full effect of the pressure rise aft of the fan.

The last items on page 2 are several notes. Notes (A) and (B) are self-explanatory. The note denoted with an asterisk (*) corresponds to any asterisk printed in the table. This note is printed to bring attention to the fact that the blade sections are stalled in the annuli so noted.

The last page of output, page 3, contains the duct surface pressure distribution if it has been requested ($NPFI \neq 0$). Again, the duct characteristics and flow conditions are printed at the top of the page. The next line lists the azimuth angles, ϕ , in degrees. Directly under the azimuth angles are the corresponding pressure coefficients on the inside ($CP(IN)$) and outside ($CP(OUT)$) surfaces of the duct. The pressure coefficients are based on the free-stream dynamic pressure ($NPRES = 1$)

$$C_p = 1 - \left(\frac{u_s}{V}\right)^2$$

or the propeller tip speed (NPRES = 2)

$$C_p = \frac{v^2 - u_s^2}{2n^2 D_p^2}$$

according to the note printed as the last line on this page.

This completes the output for one complete run. The pages that follow depend on how runs are stacked. If the same duct and fan configuration is to be run at new values of advance ratio, angle of attack, or azimuth angles, the additional output will be the same as above starting with page 1. If some change has been made in the configuration, then the complete set of output from page 0 listing the new input data will follow.

6. DESCRIPTION OF ERROR MESSAGES AND STOPS

A number of error messages and stops are built into the program so that if certain conditions occur, the computation will stop and some indication of why it was stopped will be printed on the output.

Immediately after reading in the input data, several checks are made on specific quantities. If $NPHI > 5$, it is set equal to 5 and execution continues with no error message.

If the number of propeller blades (NBLD) is less than or equal to zero, the following message is printed:

"NUMBER OF BLADES IN ERROR, NBLD = -xx"

If the convergence criterion, ϵ , is less than or equal to zero, the following message is printed:

"CONVERGENCE CRITERION MUST BE GREATER THAN 0.0"

If the angle of attack, α , is greater than or equal to 90° , the following message is printed:

"ANGLE OF ATTACK MUST BE LESS THAN 90.0 DEGREES"

If the advance ratio, J , is less than or equal to zero, the following message is printed:

"ADVANCE RATIO MUST BE GREATER THAN 0.0"

In Subroutine CLALF the propeller blade thickness-to-chord ratios are tested. If any do not fall in the range $0.0 \leq t/c \leq 0.34$, the following message is printed:

"THE BLADE THICKNESS-TO-CHORD RATIO IS OUTSIDE THE RANGE
0.0 TO 0.34"

Two error messages associated with computation of a centerbody shape are built into Subroutine HUB. If the centerbody geometry is input such that the requirements listed in section 4.3 are not met, the following message is printed:

"INPUT CENTERBODY DIMENSIONS IN ERROR"

If Subroutine HUB is unable to converge on the source and sink locations, the following message is printed:

"SUBROUTINE HUB UNABLE TO COMPUTE CENTERBODY
GEOMETRY"

If any or all of the above messages are printed, the following message is also printed:

"ERROR - EXECUTION TERMINATED"

and the program terminates execution at a STOP statement in the Main program.

The above errors are due to errors in the input data and should be simple to correct. If the program fails to converge on the inflow profile in 50 iterations, two more iterations are made. The results of iterations number 51 and 52 are output, including the optional page showing the components of the induced inflow velocities. The following messages are then printed:

"PROGRAM DID NOT CONVERGE ON INFLOW PROFILE"

"ERROR - EXECUTION TERMINATED"

and the computation terminates at the STOP statement in the Main program.

The above error is rare and has occurred in the authors' experience only under conditions of small advance ratio, $J \cos \alpha$, and small blade pitch angles. If all the input appears correct, increase $J \cos \alpha$ by increasing J or decreasing α and rerun the same case again. Also check the convergence criterion (ϵ), and consider increasing it to relax the tolerance on convergence. Experience has shown that ϵ

should not be larger than 0.01. There is approximately 10 percent difference between force and moment coefficients computed with $\epsilon = 0.01$ and $\epsilon = 0.10$. An example of a case that consistently did not converge was the Doak ducted fan (ref. 12) with 11° pitch at advance ratios less than 0.5 in axial flow.

If the duct thickness-to-chord ratio is outside the range $0.06 \leq t/c \leq 0.24$, the following warning is printed:

"DUCT PRESSURE DISTRIBUTION CALCULATION ASSUMES
T/C = x.xxx"

7. PROGRAM LISTING

The ducted fan performance analysis program is written in Fortran IV for the IBM 7094 computer. The program consists of the main program and 20 subroutines. Each source deck is identified in columns 73-80 by a four-character identification (NExx) indicating the number of the subroutine and a three-digit number sequencing the cards within the subroutine. The program listing is given in the following pages. The table below will act as a table of contents for the program listing.

8. SAMPLE CASES

In this section, the input and output for several sample cases are described. The input decks are shown in figure 6 and illustrate both methods of stacking runs discussed in section 4.1. The first case considers the ducted propeller on the Bell X-22A aircraft (ref. 13). This input deck for this case is followed by a blank card, since a different configuration follows. The second and succeeding cases consider the ducted fan used on the Doak VZ-4DA aircraft (refs. 12 and 14). There are four cases illustrated in figure 6. The first of these four, which follows the blank card, has a complete input deck. The remaining three cases, which have run numbers of 2010, 2020, and 2030, use only a single card, since only the advance ratio or the angle of attack is changed. The quantities required as input were obtained from references 12-14. The only areas in which questions might arise are the geometric camber coefficients and the centerbody configuration, both of which are discussed below.

The Bell duct has an unusual camberline shape, and the coefficients resulting from equation (48) do not yield a shape that matches the actual camberline well. A better fit to the camberline was obtained by solving equation (47) at $x/c = 0, 0.15, 0.45,$ and 0.7 . These are the coefficients shown on the third card of the input deck. The centerbody model is determined by placing the maximum centerbody radius at its true location aft of the fan. The Rankine body results in a centerbody which is larger and more blunt than the true centerbody. The shapes are compared in figure 3 of reference 1.

The camberline of the Doak duct was best fit by solving equation (47) at $x/c = 0, 0.25, 0.55,$ and 0.8 ; and these are the coefficients on the third card of the input deck for the second case. The centerbody model is determined by assuming the maximum centerbody radius to be at the propeller station. The resulting shape fits the centerbody nose very well but it is shorter in length than the true centerbody as is shown in figure 4 of reference 1.

Two runs making up the sample case output are shown in figure 7. They are the first two runs obtained from the stacked input decks shown in figure 6. Since the output was described in detail in section 5, no further comments will be given here.

9. DATA COMPARISONS

In order to give the program user some indication of the nature of the results obtained from the computer program, some comparisons with experimental data are presented. The comparisons included herein are brief because of the similarity between the current results and those included in reference 4.

Comparison between the measured and predicted total thrust coefficient on the Bell X-22A ducted propeller in axial flow (ref. 13) is shown in figure 8. These results illustrate the effect of advance ratio and fan blade pitch angle. The agreement is good until comparisons are made in regions of possible blade stall; that is, low advance ratio and high blade pitch angles. Note that the program predicts the correct trend due to blade stall when $\beta_{3/4} = 49^\circ$ even though the total thrust is overpredicted.

The total thrust coefficients presented in this report include the pressure thrust due to the increased pressure aft of the fan acting on the duct. The pressure thrust is included to give better agreement between measured and predicted duct thrust as is shown in reference 5. Thus the overprediction of the total thrust coefficient is due primarily to the predicted fan thrust as discussed in the above reference. The fan thrust is very dependent on the fan blade characteristics, and an error of 2° in the blade pitch angle can cause large differences in fan thrust.

In figure 9, the effect of angle of attack and advance ratio on the thrust, normal force, and pitching moment on the Doak ducted fan (ref. 14) are shown. The thrust and normal force agree generally with the results in reference 5; that is, the thrust is well predicted at high advance ratios and at low angles of attack, and the normal force is well predicted at high advance ratios. The major difference in results occurs with pitching moments. Reference 5 showed good prediction of pitching moments, but figure 9(c) shows poor agreement with experiment. In the early work described in references 2 and 4, some simplifying assumptions were necessary in order to compute duct pitching moments. The analysis of reference 1 removed these assumptions and showed some of them to be incorrect. Unexplainably, the more exact analysis results in poor agreement with experiment.

Comparison of predicted and measured duct surface pressure coefficients on the Doak ducted fan are shown in figures 10, 11, and 12. The present results are nearly the same as those shown in reference 4 where a larger range of conditions was investigated. Although $\alpha = 20^\circ$ is the highest angle of attack shown in figures 11 and 12, the nature of the agreement on duct pressure coefficients is the same for angles of attack as large as $\alpha = 80^\circ$.

PRESSURE COEFFICIENTS BASED ON FREE STREAM VELOCITY

(b) Concluded.

Figure 7.- Concluded.

Figure 8.- Measured and predicted total thrust coefficient on the Bell X-22A ducted propeller in axial flow.

(a) Total thrust coefficient.

Figure 9.- Measured and predicted aerodynamic coefficients on the Doak VZ-4DA ducted fan, $\beta_{\text{tip}} = 15^\circ$.

(b) Normal force coefficient.

Figure 9.- Continued.

(c) Pitching moment coefficient.

Figure 9.- Concluded.

Figure 10.- Measured and predicted pressure distribution on the Doak duct at $\alpha = 0^\circ$, $J = 0.342$.

(a) $\phi = 0^\circ$.

Figure 11.- Measured and predicted pressure distribution on the Doak duct at $\alpha = 20^\circ$, $J = 0.342$.

(b) $\phi = 180^\circ$.

Figure 11.- Concluded.

(a) $\phi = 0^\circ$.

Figure 12.- Measured and predicted pressure distribution on the Doak duct at $\alpha = 20^\circ$, $J = 0.178$.

(b) $\phi = 180^\circ$.

Figure 12.- Concluded.
