# Atomic and molecular structures of positronium, dipositronium and positronium hydride 

Raji Heyrovska<br>Institute of Biophysics, Academy of Sciences of the Czech Republic, 135<br>Kralovopolska, 61265 Brno, Czech Republic. Email: rheyrovs @hotmail.com

#### Abstract

The three positron based chemical entities, analogous to hydrogen atom, hydrogen molecule and hydride, are drawing increasing attention in the literature. While a lot is known about the binding energies, not much is known about the radii of the atoms and ions and bond lengths and structures of these exotic entities. This article brings for the first time exact values of these structural properties which are comparable with known data. It is hoped that the results will be of help for a better understanding and further development of the chemistry and physics of these exotic compounds and of their possible role as intermediates in chemical and interfacial processes.

Subject terms: Chemical physics, Physical chemistry, Atomic physics, Nuclear physics, Structural chemistry

Positronium ( Ps ), dipositronium $\left(\mathrm{Ps}_{2}\right)$ and positronium hydride ( PsH ), based on positron, an antimatter, have drawn considerable interest in recent literature. To cite a few, see. ${ }^{1-8}$ Several years ago, the author had proposed ${ }^{9}$ that, since a neutron $\left(\mathrm{n}^{0}\right)$ and a proton $\left(\mathrm{p}^{+}\right)$ decay by emitting an electron ( $e^{-}$) and a positron $\left(e^{+}\right)$respectively, an ( $\mathrm{e}^{+} \mathrm{e}^{-}$) pair, now known as positronium, could be the intermediate when neutrons and protons fuse together to form atomic nuclei. At distances ( $\mathrm{a}_{\mathrm{e}-\mathrm{e}+}$ ) of the order of $10^{-15} \mathrm{~m}$, the $\left(\mathrm{e}^{-} \mathrm{e}^{+}\right)$pair annihilates releasing two gamma photons of energy, $\mathrm{m}_{\mathrm{e}} \mathrm{c}^{2}=0.511 \mathrm{Mev}$ each. This article brings for the first time the structures of the above exotic chemical entities based on exact atomic radii. It is hoped that the results will be of help for a better understanding and further development of the chemistry and physics of these short lived compounds and of their possible yet undiscovered important role as intermediates in chemical and interfacial processes, nucleosynthesis, and biophysics.

Positronium atom, ${ }^{1-8}$ is a positron $\left(\mathrm{e}^{+}\right)$bound to an electron $\left(\mathrm{e}^{-}\right)$at a distance of the order of $10^{-10} \mathrm{~m}$ as in a hydrogen atom, H in which a proton $\left(\mathrm{p}^{+}\right)$is bound to an electron (e) at the distance of the Bohr radius, $\mathrm{a}_{\mathrm{H}}\left(\sim 0.5 \times 10^{-10} \mathrm{~m}\right)$. Dipositronium $\left(\mathrm{Ps}_{2}\right)$ is a molecule consisting of a pair of positronium atoms, ${ }^{3,6}$ like $\mathrm{H}_{2}$ where a pair of ( $\mathrm{p}^{+} \mathrm{e}^{-}$) combine to form the molecular hydrogen. Positronium hydride (PsH) is a diatomic molecule, ${ }^{4,6,7}$ which can be completely or partially covalent or ionic. Considered here are the ionization energy, Bohr radius and bond lengths in the above, based on exact atomic and ionic radii evaluated here for the first time. The observed bond lengths of PsH are comparable with the corresponding sums of the ionic and atomic radii obtained here.

The ionization energy, Bohr radius and reduced mass relation for Ps can be considered similar ${ }^{1 a, 10}$ to that for H . The ground state energy, $\mathrm{E}_{\mathrm{H}}=\mathrm{e} \mathrm{I}_{\mathrm{H}}$ (where $\mathrm{I}_{\mathrm{H}}$ is the ionization potential and e is the elementary charge), Bohr radius, $\mathrm{a}_{\mathrm{H}}$ (which is the
distance between the electron and proton) and the reduced mass, $\mu_{H, r e d}=m_{e-} m_{p+} /\left(m_{e-}+\right.$ $m_{p+}$ ) (where $m_{e-}$ and $m_{p+}$ are masses of the electron and proton respectively), are related as follows, ${ }^{11,12}$
$E_{H}=(1 / 2)\left(e^{2} / \kappa a_{H}\right)=(1 / 2) \mu_{H, r e d}(\alpha c)^{2}=e I_{H}$
where, $\kappa=4 \pi \varepsilon_{0}$, the atomic unit of permittivity, $\varepsilon_{0}$, the electric constant, $\alpha$, the fine structure constant, h, the Planck constant and c, the speed of light in vacuum. On using the latest values, ${ }^{13}$ of the physical constants, it follows that
$\mu_{\mathrm{H}, \mathrm{red}}=0.910442 \times 10^{-31} \mathrm{~kg}$
$E_{H}=(1 / 2) \mu_{H, \text { red }}(\alpha c)^{2}=2.178686 \times 10^{-18} \mathrm{~J}$
$\mathrm{I}_{\mathrm{H}}=\mathrm{E}_{\mathrm{H}} / \mathrm{e}=13.5983 \mathrm{~V}$
$\mathrm{a}_{\mathrm{H}}=(1 / 2)\left(\mathrm{e} / \mathrm{KI}_{\mathrm{H}}\right)=0.5295 \times 10^{-10} \mathrm{~m}=0.05295 \mathrm{~nm}$.

Bohr radius $\left(\mathrm{a}_{\mathrm{H}}\right)$ was shown to be the sum of two Golden sections $\mathrm{a}_{\mathrm{H}, \mathrm{e}-}$ and $\mathrm{a}_{\mathrm{H}, \mathrm{p}+}$ pertaining to the electron and proton ${ }^{11,12}$ : In equation $(1 c), I_{H}=\left(I_{p+}+I_{e-}\right) / 2$ where $I_{p}=$ $e /\left(\kappa a_{H, p+}\right)$ and $\mathrm{I}_{\mathrm{e}-}=-e /\left(\kappa a_{H, e-}\right)$ are the components of the ionization potential, and $\mathrm{a}_{\mathrm{H}, \mathrm{e}-}$ and $\mathrm{a}_{\mathrm{H}, \mathrm{p}+}$, are sections of $\mathrm{a}_{\mathrm{H}}$ pertaining to $\left(\mathrm{p}^{+}\right)$and ( $\left.\mathrm{e}^{-}\right)$respectively. Thus,

$$
\begin{align*}
& \mathrm{I}_{\mathrm{H}}=(1 / 2)\left(\mathrm{e} / \kappa \mathrm{a}_{\mathrm{H}}\right)=(1 / 2)(\mathrm{e} / \kappa)\left[\left(1 / \mathrm{a}_{\mathrm{H}, \mathrm{p}+}\right)-\left(1 / \mathrm{a}_{\mathrm{H}, \mathrm{e}}\right)\right]  \tag{6a,b}\\
& 1 / \mathrm{a}_{\mathrm{H}}=\left(1 / \mathrm{a}_{\mathrm{H}, \mathrm{p}+}\right)-\left(1 / \mathrm{a}_{\mathrm{H}, \mathrm{e}}\right) ; \mathrm{a}_{\mathrm{H}}=\mathrm{a}_{\mathrm{H}, \mathrm{e}-}+\mathrm{a}_{\mathrm{H}, \mathrm{p}+}  \tag{7a,b}\\
& \left(\mathrm{a}_{\mathrm{H}, \mathrm{e}} / \mathrm{a}_{\mathrm{H}, \mathrm{p}+}\right)^{2}-\left(\mathrm{a}_{\mathrm{H}, \mathrm{e}} / \mathrm{a}_{\mathrm{H}, \mathrm{p}+}\right)=1 \tag{8}
\end{align*}
$$

On combining equations ( $7 \mathrm{a} \& \mathrm{~b}$ ), one obtains equation (8), which is a Golden quadratic equation, whose positive root is $\mathrm{a}_{\mathrm{H}, \mathrm{e}} / \mathrm{a}_{\mathrm{H}, \mathrm{p}+}=\varphi=\left(5^{1 / 2}+1\right) / 2=1.618034 .$. , the Golden ratio, a mathematical constant. ${ }^{14}$ This shows Nature's unique construction of the atom, that $\mathrm{a}_{\mathrm{H}}$ is divided at the Golden point at the point of electrical neutrality $\mathrm{P}_{\mathrm{e} \text {, }}$, into the two Golden sections $\mathrm{a}_{\mathrm{H}, \mathrm{e}}$ and $\mathrm{a}_{\mathrm{H}, \mathrm{p}+}$ pertaining to the electron and proton. These Golden sections are given by,

$$
\begin{equation*}
a_{H, e-}=a_{H} / \varphi=0.3272 \times 10^{-10} \mathrm{~m} ; \mathrm{a}_{\mathrm{H}, \mathrm{p}+}=\mathrm{a}_{\mathrm{H}} / \varphi^{2}=\mathrm{a}_{\mathrm{H}, \mathrm{e}} / \varphi=0.2022 \times 10^{-10} \mathrm{~m} \tag{9a,b}
\end{equation*}
$$

Figure 1a shows the hydrogen atom, with the two circles of radii $\mathrm{a}_{\mathrm{H}, \mathrm{e}}$ and $\mathrm{a}_{\mathrm{H}, \mathrm{p}+}$ pertaining to the electron and proton.

In the case of positronium, Ps , which consists of an electron and a positron, equations similar to those for H hold, but with the reduced mass, ${ }^{1 \mathrm{a}, 10} \mu_{\mathrm{Ps}, \text { red }}=\mathrm{m}_{\mathrm{e}} / 2$,

$$
\begin{align*}
& \mu_{\mathrm{P}_{\mathrm{s}, \mathrm{red}}}=\mathrm{m}_{\mathrm{e}+} \mathrm{m}_{\mathrm{e}} /\left(\mathrm{m}_{\mathrm{e}+}+\mathrm{m}_{\mathrm{e}-}\right)=\mathrm{m}_{\mathrm{e}} / 2=4.554691 \times 10^{-31} \mathrm{~kg} .  \tag{10}\\
& \mathrm{E}_{\mathrm{Ps}}=(1 / 2) \mu_{\mathrm{Ps}, \mathrm{red}}(\alpha \mathrm{c})^{2}=1.089945 \times 10^{-17} \mathrm{~J}  \tag{11}\\
& \mathrm{I}_{\mathrm{Ps}}=\mathrm{E}_{\mathrm{Ps}} / \mathrm{e}=6.803 \mathrm{~V}  \tag{12}\\
& \mathrm{a}_{\mathrm{Ps}_{\mathrm{s}}}=(1 / 2)\left(\mathrm{e} / \mathrm{\kappa} \mathrm{~K}_{\mathrm{Ps}}\right)=1.0583 \times 10^{-10} \mathrm{~m}=0.10583 \mathrm{~nm} \tag{13}
\end{align*}
$$

The value of $\mathrm{I}_{\mathrm{Ps}}$ is the same as that, 6.803 V in. ${ }^{1,4,4,5}$ and $\mathrm{a}_{\mathrm{Ps}} \sim 2 \mathrm{a}_{\mathrm{H}}$. as reported in. ${ }^{2}$

Bohr radius ( $\mathrm{a}_{\mathrm{Ps}}$ ) of positronium is likewise the sum of the two Golden sections $\mathrm{a}_{\mathrm{Ps,e}}$ and $\mathrm{a}_{\mathrm{Ps}, \mathrm{e}+}$ pertaining to the electron and positron. The Golden sections of $\mathrm{a}_{\mathrm{Ps}}\left(=\mathrm{a}_{\mathrm{Ps}, \mathrm{e}+}+\right.$ $a_{P s, e}$.) give the radii of $\mathrm{e}^{-}$and $\mathrm{e}^{+}$in Ps as in the case of H ,
$\mathrm{a}_{\mathrm{Ps}, \mathrm{e}+}=\mathrm{a}_{\mathrm{Ps}} / \phi^{2}=0.4042 \times 10^{-10} \mathrm{~m} ; \mathrm{a}_{\mathrm{Ps}, \mathrm{e}-}=\mathrm{a}_{\mathrm{Ps}} / \phi=0.6541 \times 10^{-10} \mathrm{~m}$

Figure 2 a shows the positronium with the two circles of radii $\mathrm{a}_{\mathrm{Ps}, \mathrm{e}}$ and $\mathrm{a}_{\mathrm{Ps}, \mathrm{e}+}$ pertaining to the electron and positron.

As in the case of the hydrogen molecule, $\mathrm{H}_{2}$, where a proton and an electron occupy the opposite corners ${ }^{11,12}$ (see Figure 1b) of a square, dipositronium, $\mathrm{Ps}_{2}$, can be considered as a square with an electron and positron on opposite corners as in Figure 2b. The length of the covalent bond in the $\mathrm{H}_{2}$ molecule, $\mathrm{d}(\mathrm{H}-\mathrm{H})$, (see Figure 1c) is equal to the diagonal of the square with the Bohr radius, $\mathrm{a}_{\mathrm{B}, \mathrm{H}}$ as a side ${ }^{11}$ and the covalent radius, ${ }^{15}$ $\mathrm{R}_{\mathrm{H}}=\mathrm{d}(\mathrm{H}-\mathrm{H}) / 2$, as given by,
$\mathrm{d}(\mathrm{H}-\mathrm{H})=2^{1 / 2} \mathrm{a}_{\mathrm{B}, \mathrm{H}}=0.07488 \mathrm{~nm}$
$\mathrm{R}_{\mathrm{H}}=0.03744 \mathrm{~nm}$

The Golden sections of $\mathrm{d}(\mathrm{H}-\mathrm{H})$ give the cationic and anionic radii ${ }^{11,12}$ of the ionic resonance forms ${ }^{15}$ of $\mathrm{H}_{2}$ (see Figure 1d)

$$
\begin{align*}
& \mathrm{d}(\mathrm{H}-\mathrm{H})=\mathrm{d}\left(\mathrm{H}^{+}\right)+\mathrm{d}\left(\mathrm{H}^{-}\right)=0.07488 \mathrm{~nm}  \tag{17}\\
& \mathrm{~d}\left(\mathrm{H}^{+}\right)=\mathrm{d}(\mathrm{H}-\mathrm{H}) / \phi^{2}=2^{1 / 2} \mathrm{a}_{\mathrm{H}, \mathrm{e}+}=0.02860 \mathrm{~nm} \tag{18}
\end{align*}
$$

$\mathrm{d}\left(\mathrm{H}^{-}\right)=\mathrm{d}(\mathrm{H}-\mathrm{H}) / \phi=2^{1 / 2} \mathrm{a}_{\mathrm{H}, \mathrm{e}}=0.04628 \mathrm{~nm}$

The covalent bond length, $\mathrm{d}(\mathrm{Ps}-\mathrm{Ps})$ of $\mathrm{Ps}_{2}$ can similarly be obtained as the diagonal of a square with $\mathrm{a}_{\mathrm{B}, \mathrm{Ps}}$ as the sides (see Figures $2 \mathrm{~b}, \mathrm{c}$ ),

$$
\begin{align*}
& \mathrm{d}(\mathrm{Ps}-\mathrm{Ps})=2^{1 / 2} \mathrm{a}_{\mathrm{B}, \mathrm{Ps}}=0.1497 \mathrm{~nm}  \tag{20}\\
& \mathrm{R}_{\mathrm{Ps}}=\mathrm{d}(\mathrm{Ps}-\mathrm{Ps}) / 2=0.07485 \mathrm{~nm} \tag{21}
\end{align*}
$$

where the two electrons and two positrons are at the opposite corners of the square. This bond length (see Figure 2c) is nearly $2 \mathrm{~d}(\mathrm{H}-\mathrm{H})$. The covalent radius, $\mathrm{R}_{\mathrm{Ps}}$ (see Figure 2c) is comparable with half the diameter, 0.159 nm reported in. ${ }^{4}$

As in the case of hydrogen, the Golden sections of $\mathrm{d}(\mathrm{Ps}-\mathrm{Ps})$ give the radii of the cation $\mathrm{Ps}^{+}$and anion $\mathrm{Ps}^{-}$(see Figure 2d),

$$
\begin{align*}
& \mathrm{d}(\mathrm{Ps}-\mathrm{Ps})=\mathrm{d}\left(\mathrm{Ps}^{+}\right)+\mathrm{d}\left(\mathrm{Ps}^{-}\right)=0.1497 \mathrm{~nm}  \tag{22}\\
& \mathrm{~d}\left(\mathrm{Ps}^{+}\right)=\mathrm{d}(\mathrm{Ps}-\mathrm{Ps}) / \phi^{2}=2^{1 / 2} \mathrm{a}_{\mathrm{Ps}, \mathrm{e}+}=0.0572 \mathrm{~nm}  \tag{23}\\
& \mathrm{~d}\left(\mathrm{Ps}^{-}\right)=\mathrm{d}(\mathrm{Ps}-\mathrm{Ps}) / \phi=2^{1 / 2} \mathrm{aps}, \mathrm{e}-=0.0925 \mathrm{~nm} \tag{24}
\end{align*}
$$

The bond length of positronium hydride, $\mathrm{PsH},{ }^{4,6,7}$ consting of a positronium ion or atom and a hydrogen atom or ion depends on the many possible forms. ${ }^{7} \mathrm{In},{ }^{4} \mathrm{PsH}$ is considered as an atom and not molecule. However, since in PsH there are two distinct positive nuclei (a positron and a proton) sharing the two electrons, here it is considered
as a molecule. Four of the possible bond lengths obtained as the sums of the radii are given below (see Figures $3 \mathrm{a}-\mathrm{d}$ ) as examples:

$$
\begin{align*}
& \mathrm{d}\left(\mathrm{Ps}^{+} \mathrm{H}^{-}\right)=\mathrm{d}\left(\mathrm{Ps}^{+}\right)+\mathrm{d}\left(\mathrm{H}^{-}\right)=0.0572+0.0462=0.103 \mathrm{~nm}  \tag{25}\\
& \mathrm{~d}(\mathrm{PsH})=\mathrm{d}(\mathrm{Ps})+\mathrm{d}(\mathrm{H})=0.075+0.037=0.112 \mathrm{~nm} .  \tag{26}\\
& \mathrm{d}\left(\mathrm{Ps}^{-} \mathrm{H}^{+}\right)=\mathrm{d}\left(\mathrm{Ps}^{-}\right)+\mathrm{d}\left(\mathrm{H}^{+}\right)=0.0925+0.0286=0.121 \mathrm{~nm} .  \tag{27}\\
& \mathrm{d}\left(\mathrm{Ps}^{-} \mathrm{H}^{-}\right)=\mathrm{d}\left(\mathrm{Ps}^{-}\right)+\mathrm{d}\left(\mathrm{H}^{-}\right)=0.0925+0.0462=0.139 \mathrm{~nm} \tag{28}
\end{align*}
$$

In the above, $\left(\mathrm{Ps}^{+} \mathrm{H}^{-}\right),\left(\mathrm{Ps}^{-} \mathrm{H}^{+}\right)$and $\left(\mathrm{Ps}^{-} \mathrm{H}^{-}\right)$are completely ionic bonds and PsH is a completely covalent bond. The bond length $\mathrm{d}\left(\mathrm{Ps}^{-} \mathrm{H}^{+}\right)=0.121 \mathrm{~nm}$ in equation (27), is close to the electron-proton distance, $2.31 \mathrm{a}_{\mathrm{B}, \mathrm{H}}=0.122 \mathrm{~nm}$ in, ${ }^{6}$ and that of $\mathrm{d}\left(\mathrm{Ps}^{-} \mathrm{H}^{-}\right)$of equation (28) corresponds to the positron-proton distance, 0.14 nm in. ${ }^{7}$ For a comparison of the above bond lengths with those of many hydrides, see. ${ }^{16-18}$

## Summary

This work presents for the first time exact values of the radii, bond lengths, dimensions and structures of positronium, dipositronium and positronium hydride at the atomic level and it is hoped that this will be of fundamental help in the study of these exotic atoms and molecules consisting of antimatter and their possible role as important short lived intermediates in chemical, biochemical and nuclear processes
