## ABSTRACT

**Food physical chemistry** is considered to be a branch of Food chemistry [1] [2] concerned with the study of both physical and chemical interactions in foods in terms of physical and chemical principles applied to food systems, as well as the applications of physical/chemical techniques and instrumentation for the study of foods.[3] [4] [5] [6] This field encompasses the "*physiochemical principles of the reactions and conversions that occur during the manufacture, handling, and storage of foods*"[7]. Two rapidly growing, related areas are *Food Biotechnology* and *Food Biophysical Chemistry*.

**Keywords:** *Food chemistry, Physical Chemistry, Biophysical Chemistry applicationsto food systems; physical and chemical principles applied to food systems, physical/chemical techniques and instrumentation utilized for the study of foods; physical and chemical aspects of food processing; reactions in foods; chemical analysis and related physical methods of analysis.*

## 1. INTRODUCTION

Food physical chemistry concepts are often drawn from rheology, theories of transport phenomena, physical and chemical thermodynamics, chemical bonds and interaction forces, quantum mechanics and reaction kinetics, biopolymer science, colloidal interactions, nucleation, glass transitions and freezing,[8] [9] disordered/ non-crystalline solids. Techniques utilized range widely from dynamic rheometry, optical microscopy, electron microscopy, AFM, light scattering, X-ray diffraction/neutron diffraction,[10] to MRI, spectroscopy (NMR,[11] FT-NIR/IR, NIRS, Raman, ESR and EPR,[12] [13] CD/VCD,[14] Fluorescence, FCS [15] [16] [17] [18] [19] HPLC, GC-MS,[20] [21] and other related analytical techniques. Understanding food processes and the properties of foods requires knowledge of physical chemistry and how it applies to specific foods and food processes. Food physical chemistry is essential for improving the quality of foods, their stability and food product development. Because food science is a multi-disciplinary field, food physical chemistry is being developed through interactions with other areas of food chemistry and food science, such as: food analytical chemistry, food process engineering/food processing, food and bioprocess technology, food extrusion, food quality control, food packaging, food biotechnology and food microbiology.

## 2. TOPICS IN FOOD PHYSICAL CHEMISTRY

### 2.1. Topic Groups and Categories

The following are examples of topics in Food Physical Chemistry that are of interest to both Food Industry and Food Science:

- Water in foods
- Local structure in liquid water
- Micro-crystallization in icecream emulsions
- Dispersion and surface-adsorption processes in foods; Food Dispersions
- Water and protein activities
- Food hydration and shelf-life
- Hydrophobic interactions in foods
- Hydrogen bonding and ionic interactions in foods
- Disulfide bond breaking and formation in foods
- Food dispersions
- Structure-functionality in foods

- Food micro- and nano- structure
- Food gels and gelling mechanisms
- Cross-linking in foods
- Starch gelatinization and retrogradation
- Physico-chemical modification of carbohydrates
- Physico-chemical interactions in food formulations
- Freezing effects on foods and freeze concentration of liquids
- Glass transition in wheat gluten and wheat doughs
- Drying of foods and crops
- Rheology of wheat doughs, cheese and meat
- Rheology of extrusion processes
- Food enzyme kinetics
- Immobilized enzymes and cells
- Microencapsulation
- Carbohydrates structure and interactions with water and proteins
- Maillard browning reactions
- Lipids structures and interactions with water and food proteins
- Food proteins structure, hydration and functionality in foods
- Food protein denaturation
- Food enzymes and reaction mechanisms
- Vitamin interactions and preservation during food processing
- Interaction of salts and minerals with food proteins and water
- Color determinations and food grade coloring
- Flavors and sensorial perception of foods
- Properties of food additives

Ice cream or gelato in Rome, Italy

| Origin              |                                |
|---------------------|--------------------------------|
| Alternative name(s) | Gelato, sorbet, frozen custard |
| Dish details        |                                |
| Course served       | Dessert                        |
| Main ingredient(s)  | Milk/Cream, water ice, sugar   |

**Figure 1.1.** Examples of solid and glassy (non-crystalline) food dispersions that also includes ice microcrystals.

**Figure 1.2.** An example of a non-crystalline and non-Newtonian, but textured food system; this is usually classified as a gel that has a complex, hydrated network structure.

## 2.2. Paracrystal Theory and Convolution Algebra

A detailed example of physical chemistry applications to heterogeneous systems such as solid foods and food dispersions is the paracrystal theory application to X-ray and neutron scattering data from such complex systems.

**Figure 2.1.** Example of an important and major, but common, food ingredient that includes paracrystals—in this case a mixture of crystalline and non-crystalline structures.

As reported in a recent publication [21], the general theory of scattering by partially ordered, atomic or molecular, structures in terms of *paracrystals* and *lattice convolutions* was formulated by Hosemann and Bagchi in [145] using basic techniques of Fourier analysis and convolution products. A natural generalization of such molecular, partial

symmetries and their corresponding analytical versions involves convolution algebras - a functional/distribution [247, 248] based theory that we will discuss in the context of a more general and original concept of a *convolution-algebroid of an extended symmetry groupoid of a paracrystal*, of any molecular or nuclear system, or indeed, any quantum system, in general. Such applications also include quantum fields theories, and local quantum net configurations that are endowed with either partially disordered or 'completely' ordered structures, as well as in the graded, or super-algebroid extension of these concepts for very massive structures such as stars and black holes treated by quantum gravity theories.

A statistical analysis linked to structural symmetry and scattering theory considerations shows that a real paracrystal can be defined by a three dimensional convolution polynomial with a semi-empirically derived composition law, \*, [146]. As was shown in [13, 14] - supported with computed specific examples - several systems of convolution can be expressed analytically, thus allowing the numerical computation of X-ray, or neutron, scattering by partially disordered layer lattices *via* complex Fourier transforms of one-dimensional structural models using fast digital computers. The range of paracrystal theory applications is however much wider than the one-dimensional lattices with disorder, thus spanning very diverse non-crystalline systems, from metallic glasses and spin glasses to superfluids, high-temperature superconductors, and extremely hot anisotropic plasmas such as those encountered in controlled nuclear fusion (for example, JET) experiments. Other applications - as previously suggested in [12] - may also include novel designs of 'fuzzy' quantum machines and quantum computers with extended symmetries of quantum state spaces.

### 2.2.1. Convolution product of groupoids and the convolution algebra of functions

From a purely mathematical perspective, Alain Connes introduced the concept of a  $C^*$ -algebra of a (discrete) group (see, e.g., [91]). The underlying vector space is that of complex valued functions with finite support, and the multiplication of the algebra is the fundamental *convolution product* which it is convenient for our purposes to write slightly differently from the common formula as

$$(f * g)(z) = \sum_{xy=z} f(x)g(y),$$

and \* -operation

$$f(x) = \overline{f(x^{-1})}.$$

The more usual expression of these formulas has a sum over the elements of a selected group. For topological groups, where the underlying vector space consists of continuous complex valued functions, this product requires the availability of some structure of measure and of measurable functions, with the sum replaced by an integral.

Notice also that this algebra has an identity, the distribution function  $\delta_1$ , which has value one on the identity  $\mathbf{1}$  of the group, and has zero value elsewhere. Given this convolution/distribution representation that combines crystalline ('perfect' or global-group, and/or group-like symmetries) with partial symmetries of paracrystals and glassy solids on the one hand, and also with non-commutative harmonic analysis [182] on the other hand, we propose that several extended quantum symmetries can be represented algebraically in terms of certain structured *groupoids*, their

$C^*$ -convolution quantum algebroids, paragroup/quantized groups and/or other more general mathematical structures that will be introduced in this report. It is already known that such extensions to groupoid and algebroid/coalgebroid symmetries require also a generalization of non-commutative harmonic analysis which involves certain Haar measures, generalized Fourier - Stieltjes transforms and certain categorical duality relationships representing very general mathematical symmetries as well. A very promising approach to nonlinear (anharmonic) analysis of aperiodic quantum systems represented by rigged Hilbert space bundles may involve the computation of representation coefficients of Fourier - Stieltjes groupoid transforms.

Currently, however, there are several important aspects of quantum dynamics left out of the invariant, simplified picture provided by *group symmetries* and their corresponding representations of quantum operator algebras [126]. An alternative approach proposed in [140] employs *differential forms* to find such symmetries. Physicists deal often with such problems in terms of either *spontaneous symmetry breaking* or approximate symmetries that require underlying assumptions or ad-hoc dynamic restrictions that have a phenomenological basis. A well-studied example of this kind is that of the *dynamic Jahn -Teller* effect and the corresponding 'theorem' (Chapter 21 on pp. 807 - 831, as well as p. 735 of [1]) which in its simplest form stipulates that *a quantum state with electronic non-Kramers degeneracy may be unstable against small distortions of the surroundings, that would lower the symmetry of the crystal field and thus lift the degeneracy* (i.e., cause an observable splitting of the corresponding energy levels). This effect occurs in certain paramagnetic ion systems *via* dynamic distortions of the crystal field symmetries around paramagnetic or high-spin centers by moving ligands that are diamagnetic. The established physical explanation is

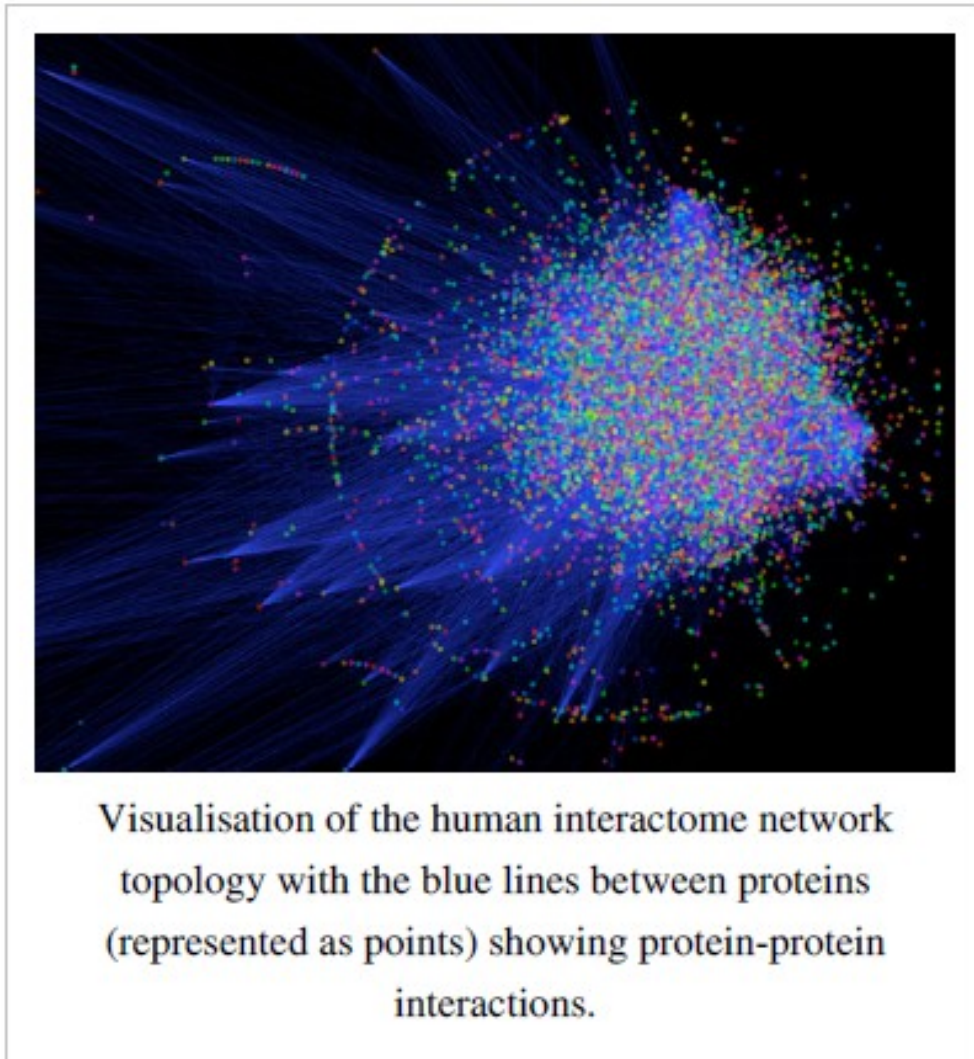

that the Jahn - Teller coupling replaces a purely electronic degeneracy by a vibronic degeneracy (of *exactly the same* symmetry!). The dynamic, or spontaneous breaking of crystal field symmetry (for example, distortions of the octahedral or cubic symmetry) results in certain systems in the appearance of doublets of symmetry  $\gamma_3$  or singlets of symmetry  $\gamma_1$  or  $\gamma_2$ . Such dynamic systems could be locally expressed in terms of symmetry representations of a Lie algebroid, or globally in terms of a special Lie (or Lie - Weinstein) *symmetry groupoid* representations that can also take into account the spin exchange interactions between the Jahn - Teller centers exhibiting such quantum dynamic effects. Unlike the simple symmetries expressed by group representations, the latter can accommodate a much wider range of possible or approximate symmetries that are indeed characteristic of real, molecular systems with varying crystal field symmetry, as for example around certain transition ions dynamically bound to ligands in liquids where motional narrowing becomes very important. This well known example illustrates the importance of the interplay between symmetry and dynamics in quantum processes. Therefore, the various interactions and interplay between the symmetries of quantum operator state space geometry and quantum dynamics at various levels leads to both algebraic and topological structures that are variable and complex, well beyond symmetry groups and well-studied group algebras (such as Lie algebras, see for example [126]).

This important example is drawn from the general theory of scattering by partially ordered, atomic or molecular, structures in terms of *paracrystals* and *lattice convolutions* that was formulated in [145] using basic techniques of Fourier analysis and convolution products. Further specific applications of the paracrystal theory to *X*-ray scattering, based on computer algorithms, programs and explicit numerical computations, were subsequently developed by the first author [13] for one-dimensional paracrystals, partially ordered membrane lattices [14] and other biological structures with partial structural disorder [16]. Such biological structures, 'quasi-crystals', and the paracrystals, in general, provide rather interesting physical examples of extended symmetries (cf. [144], [new IJRRAS]).

### 3. RELATED FIELDS TO FOOD PHYSICAL CHEMISTRY:
