Abstract

In this paper, a high-conversion-ratio bidirectional DC–DC converter with dual coupled inductors is proposed. In the boost mode, two capacitors are parallel charged and series discharged by the dual coupled inductors. Thus, high step-up voltage gain can be achieved with an appropriate duty ratio. In the buck mode, two capacitors are series charged and parallel discharged by the dual coupled inductors. The bidirectional converter can have high step-down voltage gain. The stress voltage of all switches can be reduced, and the switching loss and efficiency can be improved. The operating principle and the steady-state analyses of the voltage gain are discussed. Finally, in 24V for low voltage, and 400V for high voltage, and 200W for output power, this converter simulated in MATLAB.

Keywords: Bidirectional, DC-DC converter, dual coupled inductors, high conversion ratio

1. Introduction

Renewable energy systems are more widely used in the world such as solar and wind energy [1]-[3]. However, photovoltaic (PV) solar or wind power cannot provide sufficient power when the load is suddenly increased [4]-[6]. Because the renewable systems cannot provide a stable power for the user, the renewable energy systems and battery can be employ for the hybrid power systems [7]. When the renewable energy systems cannot supply enough power for the load, the battery must provide this power. If the power of the renewable energy systems cannot be used completely by the load, the excess energy can be used to charge the battery [8]-[10]. Because the bidirectional DC–DC converters can transfer the power between two DC sources in either direction, these converters are widely used for renewable energy hybrid power systems, hybrid electric vehicle energy systems and uninterrupted power supplies [11]-[12]. The topologies of these converters have the isolated and non-isolated types for different applications. The isolated types include the flyback type [13]-[14], forward-flyback type [15]-[16], half-bridge type [17]-[18] and full-bridge type [19]. These converters can achieve high voltage gain by adjusting the turns ratio of the transformer. The bidirectional flyback converter has the simple structure and easy control but the switches of this converter have high voltage stresses. Thus, this converter is applied for low power applications. To reduce the voltage stresses on the switches, the energy regeneration techniques used [20]. Then non-isolated types include the multi-level type, switched-capacitor type, cuk/cuk type, sepic/zeta type, buck-boost type, coupled-inductor type, three-level type and conventional buck/boost type [21]. In multi-level and switched-capacitor types, if high voltage gain needed, more switches and capacitors are required. Also, the control circuits of these converters are complicated. For the cuk/cuk and sepic/zeta types, the efficiency is low because these converters cannot provide wide voltage conversion range [22]-[24]. The converter in [25] has the high conversion ratio but this converter unidirectional. Compare with [25], the proposed converter successfully developed to bidirectional dc-dc converter with a dual coupled inductors, and the switches voltage stress reduced and efficiency increase in boost and buck mode.

The proposed bidirectional converter is analysed, and its operation in boost and buck mode is described in section II. Steady-state analysis and equations of the boost and buck mode described in section III and Simulation results described in section IV.
2. Operating Principle Of The Proposed Converter

Figure 1 shows the circuit topology of the proposed converter. This converter consists of the dc input voltage $V_L$, the power switch $S_1$, $S_2$, $S_7$, two capacitors $C_1$ and $C_2$, and the dual coupled inductors $N_P$ and $N_S$.

In the boost mode, parallel-charged and series-discharged capacitors can achieve high step-up gain. Also in the buck mode, series-charged and parallel-discharged capacitors can achieve high step-down gain. In the boost mode operation, $S_1$, $S_2$ is the main switch. The voltage across switches $S_1$, $S_2$ can be reduced. Since switches $S_1$, $S_2$ has an low voltage level, the low conducting resistance $R_{DS(ON)}$ of the switch is used to reduce the conduction loss. In the buck mode operation, the coupled inductors are used as a transformer. Thus, two capacitors $C_1$ and $C_2$ can be series charged by high voltage side and parallel discharged through the secondary side the main switches are $S_3$, $S_4$ and $S_7$. The switching loss is improved and the efficiency can be increased.

A. Boost-mode Operation

Figure 2(a) shows the waveforms and Figure 3 shows the current flow path of the proposed converter in boost mode. There are two operating modes in one switching period of the proposed converter. The main switch is $s_1$, $s_2$ for each modes. The operating modes are described as Figure 2.

1) Mode I $[t_1 - t_2]$: $S_1$, $S_2$, $S_5$, $S_6$ turn on and $S_3$, $S_4$, $S_7$ turn off in $t = t_0$. The current-flow path is shown in Fig. 3(a). The dc source $V_L$ charges the magnetizing inductor $L_m$ and the charging capacitors $C_1$ and $C_2$ via the dual coupled inductors. Voltages $V_{C_1}$ and $V_{C_2}$ are equal to $2nV_L$ and two capacitors are charged in parallel. The output capacitor $C_{out}$ provides energy to load $R$. This operating mode ends when switch $S_1$, $S_2$ is turned off at $t = t_1$.

2) Mode II $[t_1 - t_2]$: $S_5$, $S_6$, $S_7$ turn on and $S_1$, $S_2$, $S_3$, $S_4$ turn off. The current flow path is shown in Figure 3(b). The dual coupled inductors, dc source $V_L$, and capacitors $C_1$ and $C_2$ are connected in series to charge the output capacitor $C_{out}$ and load $R$. This operating mode ends when switch $S_3$, $S_4$, $S_7$ is turned off at $t = t_2$ and beginning of the next switching period.
B. Buck-mode Operation

Figure 2(b) shows the waveforms, and Figure 7 shows the current flow path for each mode. The operating modes are described below.

1) Mode I \([t_0 - t_1]: S_3, S_4, S_7\) turn on and \(S_1, S_2, S_5, S_6\) turn off. The current flow path is shown in Figure 4(a). Capacitors \(C_1, C_2\) and the secondary side coil \(N_S\) are still charged in series by \(V_{hi}\), and the magnetizing inductor \(L_m\) is also charged. The output capacitor \(C_L\) provide the energy to load \(R\). This operating mode ends when switch \(S_3, S_4, S_7\) is turned off at \(t = t_1\).
2) Mode II \([t_1 - t_2]\): \(S_1, S_2, S_5, S_6\) turn on and \(S_3, S_4, S_7\) turn off at \(t = t_1\). The current flow path is shown in Figure 4(b). The energy of capacitors \(C_1\) and \(C_2\) discharges to the output capacitor \(C_o\) and load \(R\) through the dual coupled inductors. The magnetizing inductor \(L_m\) also discharges to the output. This operating mode ends when switch \(S_1, S_2\) is turned off at \(t = t_2\).

\[\text{Figure 4. Current-flow path of the operating mode during one switching period in the buckmode}\]

### 3. Steady-State Analysis of the Proposed Converter

After the mode analysis of the boost and buck mode operations, the following equations and voltage gain in the steady-state of the proposed converter can be derived. The equations of the turn ratio of the coupled inductor are defined as

\[
n = \frac{N_s}{N_p}
\]

#### A. Boost-mode Operation

There are two operating modes in one switching period of the proposed converter. In the time period of mode I, the following equations can be written based on Figure 3(a). The voltage on the primary and secondary sides of the dual coupled inductors are shown as

\[
V_{p1} = V_L
\]

\[
V_{p1} = nV_p = nV_L
\]

Also, the voltage of capacitors \(C_1\) and \(C_2\) can be written as follows:

\[
V_{c1} = V_{c2} = 2V_p = 2nV_L
\]

Based on Figure 3(b), in modes II, the voltage on the secondary side of the dual coupled inductors can be formulated as follows:

\[
2V_{s2}^H = V_L - V_p - V_{c1} + V_{c2} - V_H
\]

\[
2nV_p^H = V_L - V_p + 4nV_L - V_H
\]

\[
V_{p2}^H = \frac{(1 + 4n)V_L - V_H}{1 + 2n}
\]

Using the volt-second balance principle on the magnetizing inductor \(L_m\), the following is given:

\[
\int_0^{DT_s} V_p^I \, dt + \int_{DT_s}^{T_s} V_p^H \, dt = 0
\]
Also, the voltage stress of the main switch $S_1, S_2$ can be expressed as

$$ V_p^{II} = V_L - V_{s1,s2} $$  \hspace{1cm} (9)

Substituting (2) and (9) into (8), voltage stress is obtained as

$$ V_{DS1,DS2} = \frac{V_L}{1 - D} $$  \hspace{1cm} (10)

Substituting (2) and (7) into (8), the voltage gain of the boost state operation is obtained as

$$ M_{boost} = \frac{V_H}{V_L} = \frac{1 + 4n - 2Dn}{1 - D} $$  \hspace{1cm} (11)

### B. Buck-mode Operation

In the time period of mode I, the following equations can be written based on Figure 4(a). The voltage on the primary and secondary sides of the dual coupled inductors are showed as

$$ 2nV_p^I = V_L - V_p^I + V_{c1} + V_{c2} - V_H $$  \hspace{1cm} (12)

$$ 2nV_p^I = V_L - V_p^I + 4nV_L - V_H $$  \hspace{1cm} (13)

$$ V_p^I = \frac{(1 + 4n)V_L - V_H}{1 + 2n} $$  \hspace{1cm} (14)

The voltage on the primary and secondary sides of the dual coupled inductors in mode II can be written based on Figure 4(b):

$$ V_p^{II} = V_i(15)V_p^{II} = nV_p^{II} = nV_L $$  \hspace{1cm} (16)

Thus, the voltage of capacitors $C_2$ and $C_3$ is also derived on Fig. 4(b). The voltage is expressed as

$$ V_{c1} = V_{c2} = 2V_p^I = 2nV_L $$  \hspace{1cm} (17)

Using the voltsecond balance principle on the magnetizing inductor $L_m$, the following is given:

$$ \int_0^{DT_s} V_p^I dt + \int_{DT_s}^{Ts} V_p^{II} dt = 0 $$  \hspace{1cm} (18)

Substituting (12) and (13) into (16), the voltage gain of the buck-mode operation is obtained as

$$ M_{buck} = \frac{V_L}{V_H} = \frac{D}{1 + 2n + 2nD} $$  \hspace{1cm} (19)

### 4. Simulation Results

To illustrate the performance and the functions of the proposed converter, this converter is implemented in the MATLAB. The specifications are:

1) dc voltage $V_i$ is 24 V and $V_H$ is 400 V;
2) output power: 200 W;
3) switching frequency: 50 kHz;
4) Coupled inductor: $N_p$:$N_s = 1$:$3$, $L_m$ = 120 $\mu$H;
5) Capacitors $C_1$ and $C_2$ is 470 $\mu$F;
6) MOSFETs $S_1, S_2, S_3, S_4$: IRFP4568PBF; $S_5$: IXFK64N50P; $S_6$: IXFK64N60P; $S_7$: IXFK64N60P;
In Figure (5), the waveforms are the boost mode operation at full load $P_o = 200$ W, $V_{in} = 24$ V, and $V_{out} = 400$ V. The waveforms illustrate that the steady-state analysis of the boost mode is correct. According to (11) and specifications, the duty cycle is 34.5%. Figure 5(a) illustrates waveform of voltage stress of switches. According to (10) stress voltage of main switches $S_1, S_2$ equal in 36.65 V. Because the proposed converter works in the boost mode, stress voltage in low side switch $S_3, S_4$ reduced. Figure 5(b) illustrate waveform of current of switches. Because the proposed converter works in the boost mode, stress voltage in low side switches $S_3, S_4$ reduced.

In Figure (6), the waveforms are the buck mode operation at full load $P_o = 200$ W, $V_{in} = 400$ V, and $V_{out} = 24$ V. According to (19) and specifications, the duty cycle is 65.5%. Figure 6(a) illustrates waveform of voltage stress of switches. Stress voltage of main switch $S_7$ is 165 V. Fig 6(b) illustrate waveform of current of switches. Because the proposed converter works in the buck mode, stress voltage in high side switch $S_7$ reduced.
Figure (7) shows the experimental efficiency of the proposed converter in boost and buck mode. The maximum efficiency in the boost mode is 98.76% at $P_o = 150$ W and full load efficiency is 98.66% at $P_o = 200$ W. The maximum efficiency in the buck mode is 98.91% at $P_o = 150$ W and full load efficiency is 98.8% at $P_o = 200$ W.

Figure (8) shows the voltage gain curves under different turn ratios of the coupled inductors in boost mode. In the boost mode, if the turn ratio increases, voltage gain will also be increased.

Figure (9) shows the voltage gain curves under different turn ratios of the coupled inductors in the buck mode. In the buck mode, if the turn ratio increases, voltage gain will be decreased.

5. Conclusion

This paper has proposed a high-efficiency, high step-up and step-down bidirectional dc-dc converter. This converter successfully developed a high-voltage gain bidirectional dc-dc converter by input-parallel output-series in the boost mode and input-series output-parallel in the buck mode. By using the two capacitors charged in parallel and discharged in series by the dual coupled inductors, high conversion ratio and high efficiency have been achieved. The voltage gain increased by using a dual coupled inductor with a low turn ratio. Simulation results show that the efficiency at full load $P_o = 200$ W is 98.66% in the boost mode and 98.8% in the buck mode.
