Ζωγραφίδου Ελένης του Στεφάνου

Υποβλήθηκε ως απαιτούμενο για την απόκτηση του Μεταπτυχιακού Διπλώματος

στη Φορολογική και Χρηματοοικονομική Διοίκηση Στρατηγικών Αποφάσεων

Φεβρουάριος, 2019

Ευχαριστίες

Με την ολοκλήρωση της διπλωματικής εργασίας, δράττομαι της ευκαιρίας να εκφράσω τις ευχαριστίες μου απέναντι στον καθηγητή και υπεύθυνο του Π.Μ.Σ. «Φορολογική και Χρηματοοικονομική Διοίκηση Στρατηγικών Αποφάσεων», κ. Καραγιώργο Θεοφάνη και στο σύνολο των διδασκόντων του προγράμματος, καθώς μου παρείχαν την ευκαιρία να παρακολουθήσω ένα πρόγραμμα μεταπτυχιακών σπουδών υψηλού επιπέδου, να εμπλουτίσω τις γνώσεις και τις δεξιότητες μου, και καθόρισαν εκ νέου την ακαδημαϊκή μου πορεία.

Ιδιαιτέρως, θέλω να ευχαριστώ τον επιβλέποντα καθηγητή, κ. Δρογαλά, για την εμπιστοσύνη που μου έδειξε σε όλα τα στάδια της συνεργασίας μας.

Τέλος, ένα μεγάλο ευχαριστώ στον Κώστα, για τη στήριξη που μου δίνει καθώς επίσης και για την τεράστια υπομονή του.

Περίληψη

Ένα από τα δυσκολότερα και πιο απαιτητικά προβλήματα κατά την επιλογή προσωπικού είναι η αξιολόγηση των πολλαπλών χαρακτηριστικών που έχουν οι υποψήφιοι. Το πρόβλημα αυτό μεγεθύνεται στις διαδικασίες επιλογής και αξιολόγησης εκλεπτυσμένου προσωπικού, όπως οι εσωτερικοί ελεγκτές. Εξ ορισμού, ένας εσωτερικός ελεγκτής πρέπει να συνδυάζει μια σειρά αναλυτικών και μη αναλυτικών δεξιοτήτων, που αντιστοιχούν σε συγκεκριμένα γνωστικά και συμπεριφορικά χαρακτηριστικά. Στην παρούσα εργασία προτείνεται ένα πλαίσιο για την επιλογή των εσωτερικών ελεγκτών χρησιμοποιώντας την τεχνική TOPSIS, ενσωματώνοντας τις συμπεριφορικές και γνωστικές δεξιότητες, αλλά και την εκτιμώμενη απόδοση του υποψηφίου. Η τεχνική AHP έχει χρησιμοποιηθεί για τον προσδιορισμό των βαρών για κάθε κριτήριο. Αποδίδοντας διαφορετική σημασία στις δεξιότητες, το προτεινόμενο πλαίσιο μπορεί να κατατάξει τους υποψήφιους και να εντοπίσει τους κατάλληλους για πρόσληψη. Για να εξεταστεί ποιό είναι το ιδανικό βάρος (σημασία) ανάμεσα στις γνωστικές και τις συμπεριφορικές δεξιότητες που μεγιστοποιούν τις επιδόσεις των υποψηφίων, εφαρμόζεται μια μη γραμμική μέθοδος προγραμματισμού. Το προτεινόμενο μοντέλο εφαρμόζεται σε μια περίπτωση επιλογής εσωτερικών ελεγκτών σε μια πολυεθνική εταιρεία.

Λέξεις κλειδιά: Επιλογή εσωτερικών ελεγκτών, Δεξιότητες, Απόδοση, AHP, TOPSIS, Μη γραμμικός προγραμματισμός

Abstract

One of the most challenging problems in personnel selection is the multi – attribute nature of the candidates. This problem is magnified in the procedure of selection of sophisticated personnel such as internal auditors. By definition, an internal auditor must combine a selection of analytical and non-analytical skills, corresponding to specific cognitive and behavioral attributes. In this study, a framework for internal auditors' selection using TOPSIS technique is proposed, integrating behavioral and cognitive skills. AHP technique has been used to determine the weights on each criterion. By assigning different importance to the later skills, the proposed framework can identify employable and potentially employable candidates. Besides the desirable skills, in the process of personnel selection, the expected performance is also considered. To examine what would be the ideal importance on cognitive and behavioral skills that maximizes candidates' performance, a Non – Linear Programming Method is applied. A real life application is demonstrated to a sample of internal auditors from a multi-national company.

1. Introduction

The rising importance of corporate governance over the past years highlighted the internal audit function and resulted in a high demand for skilled and efficient internal auditors and auditing quality (Johnson, Reichelt & Soileau, 2018;Ferramosca, D' Onza & Allegrini, 2017; Mihret, & Grant, 2017). Internal auditing is defined as "an independent, objective assurance and consulting activity designed to add value and improve an organization's operations, which helps organizations to accomplish their goals" (Cascarino, 2007; Smith, 2016).In many cases internal auditing helps the organization to discipline to legislation frameworks which would minimize risk and improve governance processes (Hayes, 2017).

The responsibilities of an internal auditor would normally fit in many different multi-discipline areas of an organization (Raiborn, Butler, Martin & Pizzini, 2017). Therefore, the subject of an internal auditor is extremely complex and would demand personnel with specific characteristics combining both technical and non-technical skills and qualitative skills, among which, integrity, agility, being objective and free from undue influence and being insightful (Seol, Sarkis & Wang, 2017; Lenning, & Gremyr, 2017; Narkchai & Fadzil, 2017; Parker & Johnson, 2017; Abbott, Daugherty, Parker & Peters, 2016; Smith, 2016).

Since the nature of the profession of an internal auditor combines multiple aspects of different skills, many of which cannot be easily quantified, the problem of internal auditors' selection differs greatly from the selection of personnel of any other profession (Cai & Jun, 2018).

Based on the aforementioned, recruitment of an internal auditor requires a methodology that would take into account qualitative characteristics of a candidate. The qualitative data that are needed to evaluate an internal auditor, concern a wide selection of non-quantifiable criteria related to professional skills such as critical thinking, problem solving, adjustability to situations, logical reasoning and personal skills such as being honest, open-minded, competitive, and can communicate his/her ideas to other colleagues (Smith, 2016). The methodologies that fit to the selection of internal auditors stem from multi-criteria decision analysis area since they can transform qualitative factors to quantifiable measures.

So far, extended research has been conducted focusing on auditors' recruitment as well as extra emphasis has been put on the auditors' characteristics that affect organizational performance. However, the selection of internal auditors using multi-criteria decision analysis methods under the criteria of cognitive, behavioral skills and performance has not been extensively investigated according to relevant literature.

In this study, ***a framework for internal auditors' selection using TOPSIS technique is proposed, integrating behavioral and cognitive skills***. The use of TOPSIS technique is recommended since the technique is constructed upon finding the minimum distance between the examined and an ideal solution. Furthermore, in order to examine what would be the ideal importance on cognitive and behavioral skills that maximizes candidates' performance a Non – Linear Programming Method is applied. The proposed framework combines behavioral and cognitive skills with internal auditors' expected performance providing a goal-oriented perspective in personnel selection.

The rest of the study is organized as follows:

In Section 2, the literature review discusses previous research on auditors' characteristics and performance and on methodologies applied in personnel selection procedure.

In Section 3, the proposed methodology is presented, demonstrating the theoretical framework.

In Section 4, the proposed framework is applied to a real life situation.

The conclusions are presented in Section 5.

2. Literature Review

2.1 Auditors' characteristics and performance

The rising demand of skilled and efficient internal auditors raises the issue of auditors' recruitment procedures the applied methodologies. The recruitment is a triple procedure including the defining of the objectives, the evaluation and rank of the candidates. In this context, a typical model for the organizational recruitment process may be applied, since incorporating sophisticated and applied tools which fit the nature of the internal auditors' profession.

The auditors' profession by its definition demands special personal attributes which are not easily measured or captured, such as ethics, independence and objectiveness. As defined by the IPPF "*internal auditing is an independent, objective assurance and consulting activity designed to add value and improve an organization's operations. It helps an organization accomplish its objectives by bringing a systematic, disciplined approach to evaluate and improve the effectiveness of risk management, control, and governance processes*" (IPPF, 2017).

Internal auditing is conducted in diverse legal and cultural environments; for organizations that vary in purpose, size, complexity, and structure; and by persons within or outside the organization. Besides the organizational differences, complying with the IIA's International Standards for the Professional Practice of Internal Auditing (Standards) is essential in meeting the responsibilities of internal auditors and the internal audit activity. The Standards, together with the Code of

Ethics, encompass all mandatory elements of the International Professional Practices Framework; therefore, conformance with the Code of Ethics and the Standards demonstrates conformance with all mandatory elements of the International Professional Practices Framework (IPPF, 2017).

The Standards use the word "must" to specify an unconditional requirement and the word "should" where conformance is expected unless, when applying professional judgment, circumstances justify deviation. The Standards comprise two main categories: Attribute and Performance Standards. Attribute Standards address the attributes of organizations and individuals performing internal auditing. Performance Standards describe the nature of internal auditing and provide quality criteria against which the performance of these services can be measured. Attribute and Performance Standards apply to all internal audit services (IPPF, 2017).

Based on the aforementioned, it becomes clear that, besides the personal skills, the international standards for the professional practice of the internal auditing set the essential guidelines for the audit activity ("must" and "should" activities) and the responsibilities of internal auditors, setting a group of technical and organizational skills (IPPF, 2013).

In the literature, the distinction between the concepts of personal characteristics and the attributes that stem from the professional expectations and requirements set two main groups of skills: cognitive skills and behavioral skills. The cognitive skills include technical skills, analytic/design skills and appreciative skills, while the behavioral skills include personal skills, interpersonal skills and organizational skills (Bailey, Gramling & Ramamoorti, 2013; Gramling & Ramamoorti, 2003, Seol & Sarkis, 2005, Seol, Sarkis & Lefley, 2011).

Lenz and Hahn (2013) revised Bailey, Gramling & Ramamoorti model by introducing: a) the relationship between internal auditor and the rest staff, the senior management and the board, b) understanding and appreciation of procedures, c) personality, d) micro factors (organizations) and e) macro factors including coercive force, adherence to the professional practices and mimetic force. Furthermore, Sanusi et al. (2018) highlight the importance of psychological constructs in terms of auditors' judgment performance based on the learning goal orientation and self-efficacy.

In an attempt to improve auditing quality several frameworks have been proposed (PCAOB, 2015a, Knechel et al., 2013), highlighting the importance of three elements: audit professionals, audit process and audit results and proposing several auditing quality indicators. Towards the measurement of audit professionals, the proposed quality indicators include technical competence, due professional care, ineffective engagement quality reviews, persons with specialized skill and knowledge, industry expertise of audit personnel, experience of audit personnel and interpretation or application of law and standards requirements (PCAOB, 2015a).

The changes in social, economic and technological environment highlight the need of adaptation of skills. These trends bring to the surface the importance of competence (Kabuye et al, 2017), IT skills (Bierstaker, Janvrin & Lowe, 2014) and communication skills in the different organizational procedures, including auditing. Auditors need to be communicative in all the situations they encounter, enhance their interpersonal skills and be aware about the impact of their mannerisms to the organization (Gene, 2005).Similarly, low quality in internal

control, stemming from lack in skills (IT expertise) may have negative impact on the organization performance (Haislip, Petersb & Richardson, 2016).

Another important factor in the recruitment process, besides auditor's skills, is the determination of the desired auditor's performance. It has been noticed that there are differences in the perception of the different stakeholders considering the drivers of internal audit effectiveness and the identification of performance measures (Erasmus & Coetzee, 2018). The Public Company of Accounting Oversight Board presents auditors' results and performance as quality segment, indicated by the followings: frequency and impact of financial statement restatement for errors, fraud and other financial reporting misconduct, financial reporting quality, timely reporting of internal control weaknesses, timely reporting of going concern issues (PCAOB, 2015a). Among the various measures applicable for auditing performance we derive convergence of/deviation from the set of goals and coverage of required level of competence (professional, organizational and managerial skills), developing, implementing and using organizational tools and techniques, adaptability (Cullen et al., 2014) employee engagement and commitment and personal development (Anitha, 2014).

Several studies revealed that auditors' personal attributes and performance affect organizations in several aspects: D' onza et al (2015) supports that effective internal auditors add value to their organizations; Mubako and Mazza (2017) found that organizational turnover may be affected by the internal auditor experience and the staff level; Muttakin, Khan and Mihret (2017) revealed that the level of discretionary accruals is positively associated with business group affiliation status while higher audit quality reduces this association; Lin (2018) concluded that auditors' incentive based compensation is negatively associated to

accruals quality and positively connected with abnormal audit fees. Elliott, Dawson and Edwards (2007) highlighted organizational deficiencies as part of compliance to standards (such as ISO 9001) that stem from the fact that internal audits are not always well received and they lack in performance. Penalties and organization inefficiencies are commonly the results of audit failure, which is proved to be related to auditors' experience and education (Ye, Cheng & Gao, 2014), while high internal organizational status and high level of internal audit competence may predict fraud management (Kabuye et al, 2017). In the context of corporate governance and compliance with the international financial standards, studies revealed that auditors' independence, expertise in accounting and in special industry promote the standards' adoption and application (Sellam & Fendri, 2017). Last but not least the internal auditing contributes to the accomplishing of the targeted objectives by the entity (Danescu, Prozan & Prozan, 2015).

Further, the auditor's gender seems to influence organizational performance according to Khlif and Achek (2017), as in their review they make obvious that female auditors influence several accounting phenomena including earnings quality, reporting policy, audit quality and analyst forecast accuracy.

On the contrary, the relation between governance and internal auditors has proved to be bidirectional, as not only the auditors affect the organizational performance, but the opposite too. In their study, Houqe et al (2015)revealed that firms in countries where with high respect to corporate governance and ethical values are more likely to hire an established auditor and that reporting quality is indirectly linked to corporate ethics. The effectiveness of auditors may also be affected by the national culture and the degree of corporate governance maturity

(Brender, Yzeiraj & Fragniere, 2015). The cultural factors not only affect the internal auditors' professionalism, independence and uniformity of practice but may also reduce training, skills and knowledge (Al-Akra, Abdel-Qader & Billah, 2016). Ballesta and Meca (2005) underlined the affect of governance on audit qualifications, opinions and reports and Alzebana and Sawan (2015) revealed that the presence of independent members of the audit committee and to those members' expertise in accounting and auditing affects the implementation of internal audit recommendations and performance. Finally, Hassan, Hijazi and Naser (2017) pointed that corporate governance mechanisms may contribute and enhance auditor performance. Recent studies reveal that technical knowledge deficiencies, burnout, multitasking, reliance on outside work (Veena et al, 2016), work stress (Yan & Xie, 2016) may affect the excellence in auditing performance and quality.

Besides the governance, other factors may influence auditors' performance such as the complex legislative design (Michael & Williams, 2018), the relationship between internal and external auditors (Alzeban & Gwilliam, 2014) and job satisfaction (Dali & Mas'ud, 2014).

2.2 Multicriteria Decision Making Methodologies

The personnel selection and evaluation problem has so far concerned many researchers and in the relevant literature a compilation of studies can be found. Among these methodologies, MCDM methodologies are applied in order to select, evaluate and rank candidates with often conflicting characteristics.

The **multiple-criteria decision-making and multiple-criteria decision analysis** are well known by the acronyms MCDM or MCDA. This analysis is dealing with structuring and solving decision and planning problems that involves multiple and different criteria. In real life problems, there does not exist a unique optimal solution and it is crucial to use the preferences of the decider in order to choose between solutions.

The main steps in the decision making process involves the following (Majunder, 2015):

Indetify the goal of the process

Select the criteria/parameters/factos/decicion makers

Select the alternatives

Select the weights to represent the imporance of each criterion/parameter

Method of aggregation
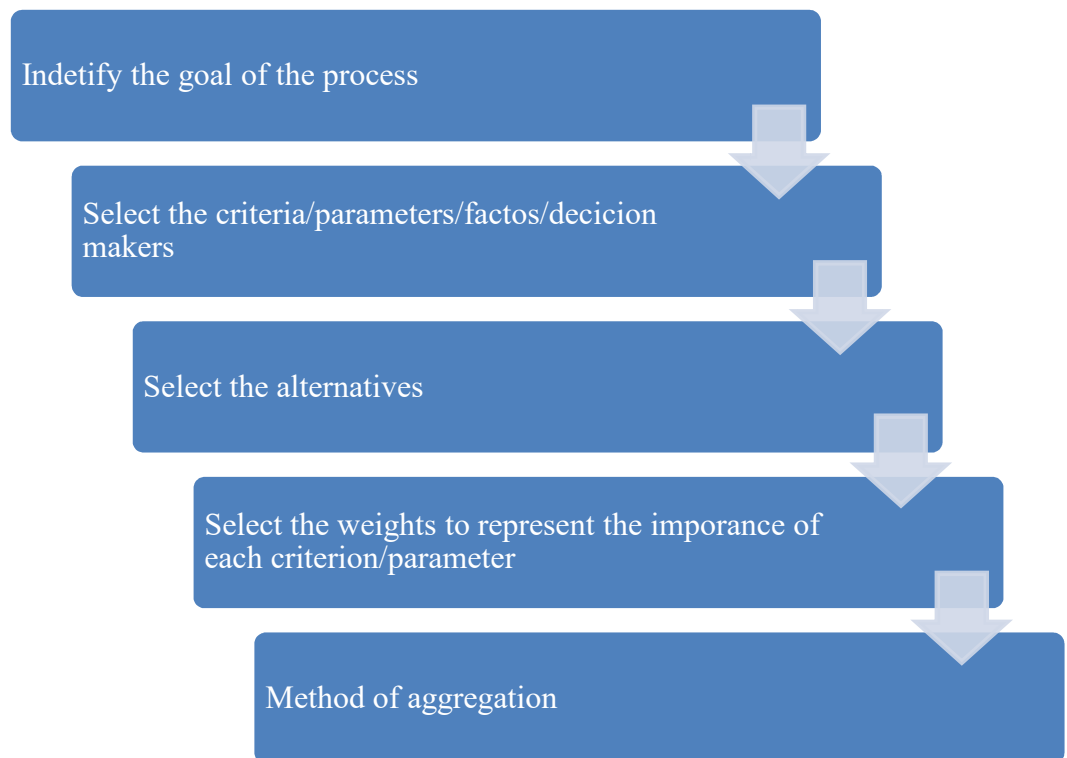

The MCDM methods are classified into two groups: compensatory and outranking methods.

A compensatory model is a rational decision-making model in which choices are systematically evaluated based on various criteria. Desirable attributes

of an alternative choice can compensate for less desirable ones—a systematic decision-making procedure has to be followed based on these compensations, because a positive score on one attribute can outweigh a negative score on another attribute. In general, a compensatory decision involves a "trading off" between good and bad attributes.

A rather different approach is the approach that is employed by the outranking method, which is based on the idea of "outranking". Here the decision makers seeks to eliminate alternatives that are, in a particular sense, "dominated". Dominance within the outranking frame of reference uses weights to give more influence to some criteria than others (Majunder, 2015).

The most popular compensatory MCDM method is the **Analytic Hierarchy Process (AHP).** The AHP is a structured technique for organizing and analyzing complex problems. At first, in the analytic hierarchy process the researcher models the problem as a hierarchy, by exploring the general and the detailed aspects of the problem and by setting several levels of hierarchy.

By definition, "*hierarchy is a stratified system of ranking and organizing people, things, ideas, etc., where each element of the system, except for the top one, is subordinate to one or more other elements*" (Majunder, 2015). Diagrams of hierarchies are often shaped roughly like pyramids, but other than having a single element at the top, there is nothing necessarily pyramid-shaped about a hierarchy and they can be described mathematically. The AHP method has been applied widely in planning and management processes and in evaluation of different systems (Majunder, 2015).

Another popular MCDM technique is ELECTRE. The acronym ELECTRE stands for ELimination Et Choix Traduisant la REalit´e (ELimination and Choice Expressing the REality). The developments in ELECTRE methods over the last decades are great. The ELECTRE methods are relevant when facing decision situations with the following characteristics (Figueira, Mousseau & Roy, 2005):

i. The problem includes more than three criteria.

ii. At least one criterion is evaluated on an ordinal scale.

iii. A strong relation exists among the different criteria.

iv. Compensation among the tradeoff of different criteria is not acceptable for the decision maker.

v. Small differences of evaluations are not significant in terms of preferences when met in only one criterion, while the accumulation of several small differences may become significant.

Besides AHP and ELECTRE, in the decision making problems, another popular MCDM technique is applied: the **Technique for Order Performance by Similarity to Ideal Solution (TOPSIS)**. TOPSIS is a useful tool when we face problems with multiple attributes. The technique is applied by researchers in the problems of comparison and ranking of different alternatives, and highlights the suitable alternative or the group of suitable alternatives.

The basic idea of TOPSIS is rather straightforward. It originates from the concept of a displaced ideal point from which the compromise solution has the shortest. The main advantages of TOPSIS are summarized in the following four (Shis, Shyr & Lee, 2007):

vi.   a sound logic that represents the rationale of human choice

vii.   a scalar value that accounts for both the best and worst alternatives simultaneously

viii.   a simple computation process that can be easily programmed into a spreadsheet; and

ix.   the performance measures of all alternatives on attributes can be visualized on a polyhedron, at least for any two dimensions.

These advantages make TOPSIS a major MADM technique as compared with other related techniques such as analytical hierarchical process (AHP).

Because MCDM is a practical tool for selection and ranking of a number of alternatives, its applications are numerous. TOPSIS has been deemed one of the major decision making techniques. In recent years, TOPSIS has been successfully applied to the areas of human resources management, transportation, product design, manufacturing, water management, quality control, and location analysis. In addition, the concept of TOPSIS has also been connected to multi-objective decision making and group decision making (Shis, Shyr & Lee, 2007). The high flexibility of this concept is able to accommodate further extension to make better choices in various situations, such as auditors' selection.

2.3 Personnel selection and evaluation methods

The personnel selection and evaluation problem has so far concerned many researchers and in the relevant literature a compilation of studies can be found.

Among these methodologies, MCDM methodologies are applied in order to select, evaluate and rank candidates with often conflicting characteristics. The proposed MCDM methods include the Analytic Hierarchy Process (AHP), the technique for order preference by similarity to ideal solutions (TOPSIS), the VIsekriterijumskaOptimizacijaiKOmpromisnoResenje: multicriteria optimization and compromise solution (VIKOR), ELimination Et Choix Traduisant la REalit´e: ELimination and Choice Translating Reality (ELECTRE II), Preference Ranking Organization METHod for Enrichment Evaluation (PROMETHEE II), Data Envelopment Analysis (DEA), expert systems (ES), analytic network process (ANP) and their hybrids. Since the main problem in human resources selection is fuzziness which stems from the difficultly that decision makers face in the process of assigning scores to candidates' characteristics in order to evaluate and rank them, the MCDM methods are often extended to the fuzzy environment combing the fuzzy set theory (Afshari, Nikolić & Ćoćkalo, 2014; Mardani, Jusoh & Zavadskas, 2015).

The application of TOPSIS in the HR field and more specific in the selection of staff has been widely used. The TOPSIS is proposed widely by researchers in the personnel selection procedures in many and different alterations and extensions. Shih, Shyur& Lee (2007) extended TOPSIS by integrating a multi-attribute decision making technique taking into account that there are more than one decision makers with different preferences and applying the proposed model in the procedure of staff selection; Kelemenis & Askounis (2010) have incorporated a concept based on the veto threshold in the ranking of candidates; the relative importance of each criterion by the decision makers and the degree of similarity and proximity among them have been introduced in the TOPSIS by

Kelemenis, Ergazakis and Askounis (2011); Sang, Liu and Qin (2015) proposed a fuzzy TOPSIS method based on Karnik–Mendel algorithm keeping computational efficient and avoiding information loss. Moreover, the TOPSIS has been combined with other techniques or method in the process of the relative weighting of hierarchical criteria, such as the technique of Structural Equation Modeling (SEM) (Karaveg, Thawesaengskulthai & Chandrachai, 2015), the Hungary assignment algorithm (Safari, Cruz-Machado, Sarraf & Maleki, 2014), Fuzzy Analytical Hierarchy Process (Kusumawardani & Agintiara, 2015, Erdem, 2016, Mediouni et al., 2018) and the principles of fusion of fuzzy information and 2-tuple linguistic representation model (Dursun & Karsak, 2010).

The fuzzy VIKOR method is applied in problems that require the selection from a set of different solutions or alternatives in a fuzzy environment and their ranking close to the ideal. As a methodology, it has been applied in personnel selection and evaluation problems in cases where the decision maker is not able to express preference in the first steps of the system design. For solving the problem of personnel selection and evaluation of overall performance taking into account a set of information culture criteria an integrated fuzzy MCDM approach has been proposed. In their study Alguliyev, Aliguliyev and Mahmudova (2015), after the determination of the evaluation criteria, the problem of personnel evaluation was approached by means of modified VIKOR under a fuzzy environment. The relative weight of each criterion was determined by applying the "worst case" method and the ranking of alternatives was approached based on the modified fuzzy VIKOR method. Another algorithm that has been applied in the process of staff selection is ELECTRE (Rouyendegh & Erkan, 2012, And Wu and Chen, 2011, Afshari et al, 2010).

Amongst the different MCDM methods and models applied in personnel evaluation and selection several combinations have been proposed such as: a combination of stepwise weight assessment ratio analysis (SWARA) and grey additive ratio assessment (ARAS-G) methods (Heidary Dahooie et al, 2018); the application of Fuzzy ARAS and Fuzzy MOORA (Multi-Objective Optimization on basis of Ratio Analysis) which are integrated through group decision making (GDM) method (Bos & Chatterjee, 2016); combination of the additive ratio assessment method with fuzzy numbers (ARAS-F) and the AHP (Keršulienė & Turskis, 2014); a framework composed of fuzzy ANP, fuzzy TOPSIS and fuzzy ELECTRE methods (Kabak, Burmaoğlu & Kazançoğlu, 2012); the extensions of MOORA (Baležentis, Baležentis & Brauers, 2012); a combination of analytic network process (ANP) and PROMETHEE with the visual techniques of graphical representation of actions evaluated on two criteria (GAIA plane) and the stacked bar chart (Ishizaka & Pereira, 2016); an integration of Delphi method, a Fuzzy Decision Making Trial and Evaluation Laboratory (DEMATEL) and Fuzzy Analytic Network Process (ANP) method (Aghaee & Aghaee, 2016).

The Analytic Hierarchy Process has also been applied in personnel selection problems but in a limited extension (Pant et al., 2014, Manoharan, Muralidharan & Deshmukh, 2011, Aggarwal, 2014, Güngör, Serhadlioğlu & Kesen, 2009). Other approaches in literature towards personnel selection, evaluation and ranking include the application of amalgamated fuzzy systems, ANNs, Genetic algorithms (Rashidi, Jazebi, & Brilakis, 2010), the use of Hamming distance method (Saad et al., 2014) and decision support tools using an integrated analytic network process (ANP) and fuzzy data envelopment analysis (DEA) (Lin, 2010).

Based on the aforementioned, it is clear that ***the current literature lacks the existence of a comprehensive framework for the personnel selection problem that considers both the employees characteristics and their performance. So far, the auditors' selection problem has been approached either by highlighting on the auditors' characteristics or by summarizing the effects of auditors performance on business***. There is thus significant potential and the need for further research into the internal auditors' selection problem. A TOPSIS model that could rank the different candidates providing better discrimination between candidates, based on specific cognitive and behavioral skills selected by the HR department taking into account their performance, fills the current literature gap.

3. Methodology

3.1 Proposed Model

The proposed model extends the work of Seol & Sarkis, 2005, considering extra criteria and applying TOPSIS methodology for the multiple attributes, behavioral and cognitive for internal auditor selection. As seen in the literature, the majority of the papers that present multicriteria decision analysis techniques for internal auditors' selection do not examine the robustness of the solution which is important since the weights assigned or derived (from pair wise comparisons) are subjective. In this study, the robustness of the solutions is investigated with the use of Non-Linear Programming.

3.2 Novelty and Contribution

The contribution of the proposed framework is threefold. Firstly, scenarios are examined for multiple weight combinations on each aspect (cognitive and behavioral) based on which internal auditors will be ranked upon. In conjunction with the score of each internal auditor to each criterion, different weight representations lead to different internal auditors' ranking providing better discrimination between employable candidates, quasi – employable candidates and non-employable candidates.

Secondly, in this study, a new score is proposed considering the performance which also plays a significant role in the internal auditors' selection.

Finally, to investigate the link between high performance and the optimal weight of candidates' cognitive and behavioral skills, a Non-Linear Programming Model is proposed.

The proposed approach is a new framework for selecting internal auditors by correlating candidates' skills with their expected performance (Table 1). Both the theoretical background and the combination of TOPSIS/Non-Linear Programming Model are novel to the relevant literature.

.

Table 1: Top and bottom level criteria for Internal Auditors' (IA) selection.

Cognitive skills		
Technical skills	**Analytic/Design problem structuring and solving skills**	**Appreciative skills judgment / synthesis**
T 1. Using information technology – audit software T 2. Apply control system designs and procedures T 3. Apply laws and regulations T 4. Apply internal auditing technologies and procedures T 5. Documentation of internal audit work	AN 1. Analyzing commercial and financial data AN 2. Basic analysis of accounts and accounting reports AN 3. Internal audit requirements analysis/definition AN 4. Using non-financial evaluation methods in internal audit work AN 5. Developing prototype solutions to problems	APP 1. Finding all that is relevant APP 2. Risk awareness APP 3. Seeing anomalies and recognizing their implications APP 4. Interpreting relevant laws and standards APP 5. Managing complexity

Behavioral skills		
Personal skills	**Interpersonal skills**	**Organizational skills**
PER 1.Decisive PER 2.Dedication PER 3.Intuitive/gut-feel PER 4.Proactive PER 5.Professional demeanor	INT 1. Communication – persuasiveness INT 2. Influencing, persuading, motivating, changing others INT 3. Handling multi-tasking INT 4. Leaderships – of teams, groups INT 5. Facilitation	ORG 1. Adapting internal audit work to a wide range of organizational systems, methods, and standards ORG 2. Scheduling ORG 3. Attaining a knowledge of the business (products, strategies, processes, markets, risks) ORG 4. Finding way around organizations ORG 5. Building trust

Performance (*based on HR department suggestion*)	
Goal Oriented	**Coverage of required level of competence (professional, organizational and managerial skills)**
GOAL 1. Achievement of quality objectives GOAL 2. Achievement of quantitative objectives	COMP 1. Provide accurate problem solutions COMP 2. Adaptability COMP 3. Application of Law and Standards COMP 4. Adherence to administrative procedures COMP 5. Developing, implementing and using organizational tools and techniques

3.3. Mathematical formulation

In this section, the mathematical formulation of the study will be presented. Since the selection of an internal auditor is complex as the decision maker has to examine different often conflicting criteria or to examine cognitive and behavioral criteria, the Technique for Order Preference by Similarity to an Ideal Solution (TOPSIS) method will be used. The advantages of TOPSIS technique lie on the fact that it is very simple to construct the problem, it is easily comprehendible and demonstrates adequate computational efficiency since allows the weighting of each criterion (regardless of the level) from the decision maker. On the contrary, Analytical Hierarchy Process (AHP) can be potentially applied to the problem of personnel, however, an increase of the size of the problem will lead the decision maker(s) to meaningless pairwise comparisons among criteria.

Assuming that there are i alternatives and j criteria. Initially, the matrix of scores per alternative i and criterion j is denoted with $x_{i,j}$. The scores of the matrix $x_{i,j}$ can express either benefit functions which is approximated by an increasing scale (small values are worse, large values are better) or by cost functions which is approximated by decreasing values (large values are worse while small values are better). The structure of the problem is formulated in a hierarchical form, as shown in Figure 1.
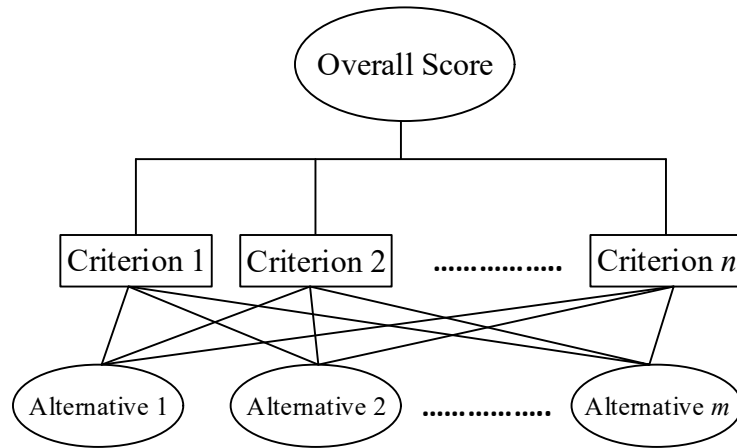

Figure 1: Typical hierarchical structure of multi-criteria decision problem

According to Figure 1, each alternative is ranked based on weight of the criteria of the problem. The structure of the hierarchy may consist of multiple levels of criteria. The criteria that are placed on the upper level are called upper level criteria while the second layer consists of the bottom level criteria.

Assuming that A_i are potential alternatives (internal auditors) and C_j are criteria based on which the alternatives will be ranked upon. Having defined some basic terms, the TOPSIS technique consists of the following steps:

Step 1. Construct the decision matrix and weights of criteria: Since the scores of each alternative to each criterion can potentially receive any value, then the following stands for decision matrix $x_{i,j} \in \mathbb{R}$. Also, the preference or the relative importance of each criterion is expressed with weights $(w_j, j = 1, \dots, n)$ such that $\sum_{j=1}^{n} w_j = 1$.

Step 2. Normalized decision matrix calculation: It is common that the alternatives in the decision matrix $x_{i,j}$ cannot be compared against each other due to difference in units of measurement. In order to override this obstacle, the scores of the decision matrix are normalized, yielding non-dimensional attributes. There are multiple methods for obtaining normalized scores $(n_{i,j})$ of decision matrix $(x_{i,j})$ which are the following (if the scores of the decision matrix are expressed by a benefit function):

    a. $n_{i,j} = \dfrac{x_{i,j}}{\sqrt{\sum_{j=1}^{n} x_{i,j}^2}}, i = 1, \dots, m, j = 1, \dots, n$

    b. $n_{i,j} = \dfrac{x_{i,j}}{max_i(x_{i,j})}, i = 1, \dots, m, j = 1, \dots, n$

    c. $n_{i,j} = \dfrac{x_{i,j} - min_i(x_{i,j})}{max_i(x_{i,j}) - min_i(x_{i,j})}, i = 1, \dots, m, j = 1, \dots, n$

Step 3. Calculation of the weighted normalized decision matrix: Since each criterion does not have the same relevant importance, the normalized matrix $(n_{i,j})$ is multiplied with the corresponding weight (w_j) expressed with the following formula:

$$v_{i,j} = w_j \times n_{i,j}, i = 1, \dots, m, j = 1, \dots, n$$

Step 4. Calculation of positive ideal and negative anti-ideal points: Due to the multi-criteria nature of the problem, the alternatives can exhibit extreme performance on a criterion (positive ideal point) or reverse extreme performance on a criterion (negative ideal point). The positive ideal point is expressed as follows:

    a.   **Positive ideal point:** $v_j^+ = max_i(v_{i,j}), j = 1, \ldots, n$

    b.   **Negative anti-ideal point:** $v_j^- = min_i(v_{i,j}), j = 1, \ldots, n$

Step 5. Calculation of distance (separation measures) from ideal and anti-ideal point: For each of the aforementioned cases (ideal and anti-ideal points), the distance of each normalized score of alternative i is calculated using the following formulas:

    a.   **Separation of each alternative from the positive ideal point**:

$$d_i^+ = \left(\sum_{j=1}^{n} (v_{i,j} - v_j^+)^p \right)^{1/p} , j = 1, \ldots, n$$

    b.   **Separation of each alternative from the negative anti-ideal point**:

$$d_i^- = \left(\sum_{j=1}^{n} (v_{i,j} - v_j^-)^p \right)^{1/p} , j = 1, \ldots, n$$

The Minkowski distance (or separation) measures as formulated above, turn into Euclidean distance for $p = 2$ and while for $p = \infty$ then

$$d_i^+ = max_j |v_{i,j} - v_j^+|$$

$$d_i^- = max_j |v_{i,j} - v_j^-|$$

Step 6. Calculation of relative distance to positive ideal position: The overall score for each alternative i is calculated with respect to d_i^+ and d_i^- as follows:

$$R_i = \frac{d_i^-}{d_i^- + d_i^+}, i = 1, \dots, m$$

For each alternative i, $0 \leq R_i \leq 1$, while the alternatives are ranked based on the values of R_i in a descending order.

In most cases, a single level of criteria is not realistic. In this case, the hierarchical structure consists of upper level criteria (Criteria A, and B) and bottom level criteria (Criterion 1,…,Criterion n-1, Criterion n) as shown in Figure 2.
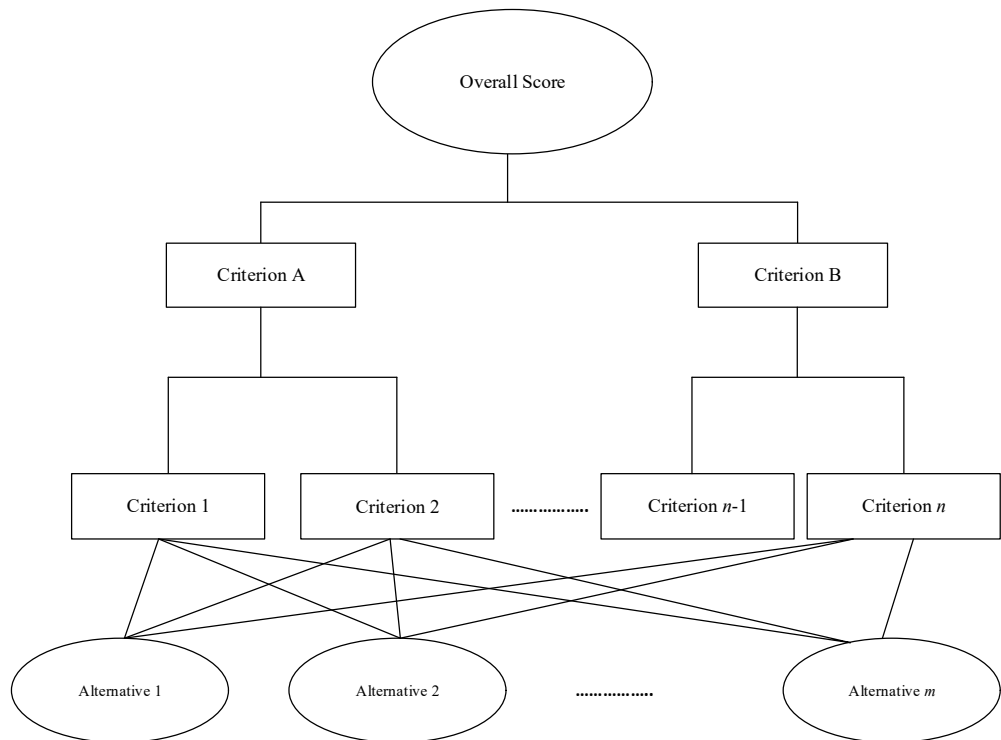

Figure 2*: Typical hierarchical structure of multi-criteria decision problem with multiple levels of criteria*

Since the formulation of TOPSIS as described above, is applied to specific criteria, the overall score of the multiple level structural form is calculated as follows:

$$R_i^{OV} = \sum_{k=1}^{K} w_k^{up} \cdot R_i \, , i = 1, .., m \qquad (1)$$

In (1), R_i^{OV} is the overall score of alternative i defined as the sum of product the upper level criteria with the scores derived from TOPSIS method (R_i). Upper level criteria can be either set directly or can be calculated based on pairwise comparisons from AHP (Kelemenis&Askounis, 2010).

3.4 Sensitivity analysis

In MCDM methodologies, sensitivity analysis is very important since the output (ranking of alternatives) is often based on subjective data. These data concern either judgments of decision makers regarding the alternatives or weights on each criterion (both upper and bottom level). To check the robustness of the solution, different scenarios on criteria can be applied. Consequently, each scenario realization will lead to non-unique ranking allowing the decision maker to examine the range of weights for which each alternative becomes first, second and so on.

Assuming that $s(s = 1, .., S)$ is the set of scenarios, then for different scenarios on either upper of bottom level criteria, then the corresponding overall score ($R_{i,s}^{OV}$) of alternative i for each weight scenario s, is calculated as follows:

$$R_{i,s}^{OV} = \sum_{k=1}^{K} w_{k,s}^{up} \cdot R_i, s = 1, .., S \, , , i = 1, .., m \qquad (2)$$

4. Application and Results

4.1 Application to Internal Auditors' selection problem

As discussed in the previous sections, the problem of selecting an Internal Auditor is complex since several criteria covering all aspects of the individual have to be taken into consideration. The relevant literature separates the criteria of internal auditor selection into two large categories of skills, namely cognitive and behavioral. The first category of skills is further analyzed into Technical, Analytic (problem structuring and solving) and Appreciative skills as shown in Table 2.

Table 2: Description of cognitive skills

Cognitive skills		
Technical skills	**Analytic/Design problem structuring and solving skills**	**Appreciative skills judgment / synthesis**
1. Using information technology – audit software 2. Apply control system designs and procedures 3. Apply laws and regulations 4. Apply internal auditing technologies and procedures 5. Documentation of internal audit work	1. Analyzing commercial and financial data 2. Basic analysis of accounts and accounting reports 3. Internal audit requirements analysis/definition 4. Using non-financial evaluation methods in internal audit work 5. Developing prototype solutions to problems	1. Finding all that is relevant 2. Risk awareness 3. Seeing anomalies and recognizing their implications 4. Interpreting relevant laws and standards 5. Managingcomplexity

Expect for cognitive skills, another important category for internal auditor selection is the behavioral skills. This category of skills emphasizes more on factors that concern the personality of the individual and are further analyzed to Personal, Interpersonal and Organizational skills (Table 3).

Table 3: *Description of behavioral skills*

Behavioral skills		
Personal skills	**Interpersonal skills**	**Organizational skills**
P1 P2 P3 P4 P5	INT1 INT2 INT3 INT4 INT5	ORG1 ORG2 ORG3 ORG4 ORG5

The structure of the problem graphically is shown in Figure 3.

Figure 3: Hierarchical structure of the proposed model

Another factor that plays an important role to the selection of an Internal Auditor is performance. From literature surveys, performance consists of two sub-factors namely goals and competency (as shown in Table 1).The data for each

4.2 Application data

The data of the problem are shown in Tables (4 – 9). For each alternative, a continuous score between 1 (lower value) and 10 (higher value) of each alternative (internal auditor) to each criterion.

In this study, 10 internal auditors (IA1,…,IA10), have been selected from a multi-national company from the branch of Greece. Both the name of the company and the name of the Internal Auditors have been anonymized.

Table 4: Scores of Internal Auditors to Technical skills

	T1	T2	T3	T4	T5
IA1	2.55	8.59	5.95	3.71	3.63
IA2	3.02	4.15	8.71	1.60	5.50
IA3	9.98	6.21	9.92	7.86	2.18
IA4	6.76	2.44	3.25	7.02	4.92
IA5	4.24	4.16	2.18	2.35	6.30
IA6	8.48	3.08	6.99	7.98	3.73
IA7	1.99	5.52	2.44	8.85	3.39
IA8	3.57	6.35	7.50	6.65	5.17
IA9	4.72	2.06	3.83	1.42	4.05
IA10	2.64	6.81	6.05	7.93	3.68

In Table 4, the scores of each Internal Auditor are shown with respect to Technical Skills (T1 – T5). It can be seen that IA1 is given a low score in T1 (Using information technology – audit software) equal 2.55 while the largest score is assigned to T2 (Apply control system designs and procedures) which is equal to 8.59.

Similarly, the data for the rest of the skills/criteria (Analytic – problem solving, Appreciative, Personal, Interpersonal, Organizational) are given in the next tables.

Table 5: Scores of Internal Auditors to Analytic/Design problem structuring and solving skills

The weights assigned to each sub-criterion of the cognitive skills are shown in Table 10; the weights have been selected from the decision maker, which is Human Resources (HR) manager of the company.

Table 10: Weights for each sub-criterion of cognitive skills

Technical skills	weight
T1	0.2
T2	0.1
T3	0.1
T4	0.3
T5	0.3
Analytical skills	**weight**
AN1	0.1
AN2	0.1
AN3	0.05
AN4	0.55
AN5	0.3
Appreciativeskills	**weight**
APP1	0.05
APP2	0.3
APP3	0.2
APP4	0.2
APP5	0.05

The weights assigned to each sub-criterion of the behavioral skills are shown in Table 11.

Table 11: Weights for each sub-criterion of behavioral skills

Personal skills	weight
PER1	0.1
PER2	0.2
PER3	0.3
PER4	0.2
PER5	0.2
Interpersonal skills	**weight**
INT1	0.15
INT2	0.3
INT3	0.2
INT4	0.15
INT5	0.2
Organizational skills	**weight**
ORG1	0.15
ORG2	0.4
ORG3	0.15
ORG4	0.15
ORG5	0.15

Each sub-criterion is weighted to form a latent structure (Cognitive and Behavioral). More specifically, to form the cognitive skills factors, technical skills are weighted with 40%, analytical skills with 40% and appreciative skills with 20%. Regarding the behavioral skills factor, the personal skills are weighted with 20%, interpersonal skills with 45% and organizational skills with 35%. Finally, both cognitive and behavioral skills are equally weighted to form the overall score of each internal auditor.

The performance aspect, measures the skills of the potential internal auditor in terms of goals (Goal Oriented), and Competence skills (referring to managerial skills of each internal auditor) as shown in Table 1. The data for each aspect are presented in Table 12 and 13. The goal aspect consists of two sub-factors as shown in Table 1. The scores for each factor are given in Table 12.

Table 12: Scores of Internal Auditors with respect to Goal Skills (Performance)

	GOAL1	GOAL2
IA1	5,54	8,48
IA2	6,42	1,74
IA3	6,20	6,34
IA4	7,15	2,43
IA5	3,99	3,84
IA6	5,68	4,27
IA7	2,51	7,15
IA8	5,55	6,19
IA9	7,48	7,15
IA10	1,18	8,56

The data for the competence sub-factor of performance are presented in Table 13.

Table 13: *Scores of Internal Auditors with respect to Competence Skills (Performance)*

	COMP1	COMP2	COMP3	COMP4	COMP5
IA1	7,39	2,40	6,50	6,95	2,75
IA2	4,27	6,62	7,58	4,73	2,42
IA3	1,11	1,09	9,57	9,79	9,70
IA4	8,71	2,27	1,45	5,98	2,66
IA5	9,95	8,28	3,76	1,79	4,87
IA6	4,15	2,06	6,27	5,01	4,71
IA7	9,23	2,92	3,02	5,88	6,68
IA8	3,95	2,34	9,36	3,26	1,56
IA9	3,79	1,36	8,39	3,08	4,69
IA10	3,72	5,00	7,44	6,34	2,18

The weights for each criterion of Goal sub-factors, are 0.6 for GOAL1 and 0.4 for GOAL2. Regarding the competence sub-factor, each criterion is equally weighted (0.2 for the weight corresponding to COMP1,…,COMP5).

4.3 Internal Auditor's Selection Results

The results of the model are shown and discussed in this section. Initially, for each internal auditor (IA1 – IA10), an overall score is calculated based on the weight representations as shown in Tables 3 – 10 and discussed in the Data sub-section. The results of the overall score as described in (1) are shown in Table 14.

Since $0 \leq R_i^{OV} \leq 1$, each internal auditor is ranked on the descending order of values of R_i^{OV}.

Table 14: Overall scores for each Internal Auditor

Internal Auditor	R_i^{OV}
IA1	0.40
IA2	0.53
IA3	0.52
IA4	0.43
IA5	0.54
IA6	0.54
IA7	0.50
IA8	0.63
IA9	0.45
IA10	0.47

Therefore, the ranking is the IA8 ≻ IA6 ≽ IA5 ≻ IA2 ≻ IA3 ≻ IA7 ≻ IA10 ≻ IA9 ≻ IA4 ≻ IA1 whereas, A≻B indicates that A is preferred to B.

4.4 Sensitivity analysis results

In order to examine the ranking of each internal auditor with respect to different weight representations, sensitivity analysis is performed. In many cases, it helps understand the range at which the solution is robust. By changing the weights on the top – level criteria, namely cognitive and behavioral, from 0 to 1 such that $w^{up}_{cogn,s=1} = 0.01$ while $w^{up}_{beh,s=1} = 1 - w^{up}_{cogn,s=1} = 1 - 0.01 = 0.99$ then the ranking for all scenarios are shown in Figure 4.

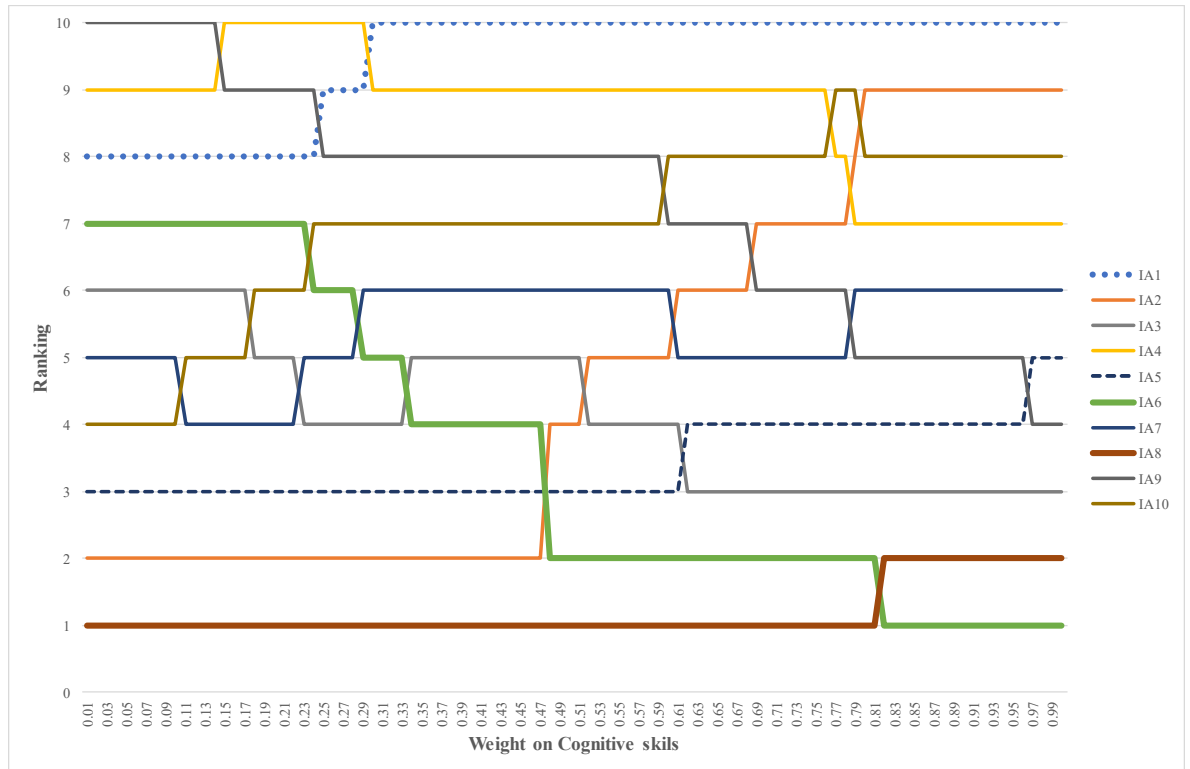

Figure 4: Sensitivity analysis of the ranking of each Internal Auditor

From Figure 4, the sensitivity analysis of the ranking of each internal auditor can be seen. Each line corresponds to the ranking of each internal auditor with respect to changes of the weight on cognitive skill. Thus, for very low importance on cognitive skills which corresponds to high importance to

behavioral skills since $w_{cogn}^{up} + w_{beh}^{up} = 1$, internal auditor 8 is ranked first while, for $w_{cogn}^{up} \geq 0.8$ internal auditor 6 is ranked 2nd. This analysis also identifies internal auditors that can potentially improve, like internal auditor 9 which is ranked as 6th for low values in the cognitive criterion (or larger values in the behavioral criterion) and is ranked as 3rd for high values in the cognitive criterion, and those who can potentially worsen their ranking, like internal auditor 1 which is ranked as 8th for low values in the cognitive criterion and for $w_{cogn}^{up} \geq 0.3$ is ranked as 10th.

4.5 Calculation of weights with Non-Linear Programming

The interaction between hierarchical structures can provide valuable results. For example, in the proposed model two different scores have been calculated for the selection of Internal Auditors; one which is derived from cognitive and behavioral skills and the performance. Assuming that performance drives the selection of Internal Auditors based on cognitive and behavioral skills then the corresponding weights can be calculated based on the following Non-Linear Programming (NLP) model (3):

$$\min d = \sqrt{\sum_{i=1}^{m} \left(R_i^{OV} - Perf_i\right)^2}$$

$$s.t.$$

(3)

$$R_i^{OV} = w_{cog} \cdot R_i^{COG} + w_{beh} \cdot R_i^{BEV}$$

$$w_{cog} + w_{be} = 1$$

$$w_{cog}, w_{beh} \geq 0$$

Model (3) is Non-Linear due to the existence of Non-Linear terms (square root and power).Aim of the model is to minimize the distance (denoted with variable *d*) between the overall score as composed by behavioral and cognitive skills (R_i^{OV}) and performance overall score ($Perf_i$) for each internal auditor *i*.

The advantage of this extension lies on the fact that the weights on one structure are objectively assigned based on another structure, therefore a comparison can be made in the end between the weights that were initially assigned and the calculated ones.
Figure 5*: Robustness analysis of the weights*

In Figure 5, the weights as derived from the Non-Linear programming model measuring the overall score based on Cognitive and Behavioral and Performance models are presented. With w Goal and w Comp the weights from Performance model are provided to extract objectively the weights on Cognitive and Behavioral factor. From Figure 5, it can be seen that by covering the spectrum of weights from 0 to 1 (with w Goal and w Comp), the results on the w Cog and w Beh seem to be quite robust, providing values in the range of [0.45, 0.61] for the Cognitive and the range of [0.38, 0.55] for the Behavioral. The center of each interval is 0.53 and 0.46 respectively. The results enforce the initial assignment of weights to each sub-factor (0.5 for Cognitive and 0.5 for Behavioral).

5. Conclusions

One of the most important departments of business nowadays is that of Internal Audit. This department provides services that relate to several subjects of the company, among which, the investigation of the correctness of the operations conducted among all departments. In most of the cases, an internal auditor may not have to do complex calculations of data, but needs to have a selection of skills which cannot be easily quantified. Therefore, the problem of selecting the right candidate for an internal audit position is not an easy task.

In this study, TOPSIS technique was employed to calculate an overall score based on which each internal auditor will be finally ranked. The scores on each factor and sub factor, for Internal Auditor selection, were derived based on a real-life application from the HR department of a multi-national company in Greece. The weights have been calculated using AHP technique. The proposed model can identify successfully the ranking of internal auditors. Also, by examining scenarios on weights, different rankings are derived. For example, an internal auditor that is ranked 6th with a specific combination of weights in cognitive and behavioral skills is ranked as 2nd if the importance on the aforementioned skills is altered.

To investigate the robustness of the proposed solution, an NLP model is solved in order to compare the weights of the overall score between two TOPSIS models. More specifically, the weights proposed in performance, also derived by TOPSIS, were used to calculate the weights on cognitive and behavioral skills. Results show that the initial assignment of weights on cognitive and behavioral skills is close to the results from the NLP model which were derived through

optimization. The model is extended to bottom level criteria using a LP model using fixed values from the NLP model which minimizes the distance between the two structures. From the LP model which was solved to determine the optimal values for weights of the bottom level criteria, it is concluded that the technical and analytic criteria share equal importance whereas the weight on the appreciative criterion is 20%. From the behavioral skills, the interpersonal criterion has the highest importance whereas the personal criterion has the lowest importance.

The proposed model can be applied in any type of personnel selection problem and can provide valuable insight by examining scenarios on the weights on each criterion (top or bottom level). One of the characteristics of the proposed framework is the determination of non-employable, quasi-employable and employable internal auditors by altering the weights on each criterion. Future directions entail the use of simulation or two stage process techniques based on the criteria examined.
