## PREFACE

In the first volume of this study - commissioned by the Commission of the European Communities within the framework of the FADN programme - a survey is given of the economic situation of agriculture in Less Favoured Areas of the EC-10. This first volume is available at LEI-DLO as part of the series Onderzoekverslagen (Research Reports) (Tammeringa, 1991). Main subjects in that report are:

- relations of agricultural development with the socio-economic situation in a region;
- agricultural income in Less Favoured Areas in comparison with normal areas, and
- reasons for these income disparities.

The results in chapter 4 of the first volume are based on the results that are described here. As chapter 4 of the first volume may be regarded as a summary of the second volume, including the main conclusions, in this second volume no summary and conclusions are included.

## 1. INTRODUCTION AND METHOD

### 1.1 Introduction

While in the first volume, we presented the more general results, here a more detailed analysis of the agricultural income situation per farming type in the Mountain and Other Less Favoured Areas of the EC-10 will be given. Furthermore, reasons for income differences will be analyzed. The data are mainly derived from the Farm Accountancy Data Network (FADN) and cover the financial years 1984, 1985 and 1986. The results are computed as the average of these three years.

Only farming types with a significant number of farms in Less Favoured Areas will be analyzed:

- Cereal farms
- General cropping farms
- Horticultural holdings
- Vineyards
- Permanent crop holdings
- Dairy farms
- Drystock farms
- Mixed farms

Furthermore, only those countries and regions that have an important representation of these farming types in Less Favoured Areas, will be taken into account (see the first volume, table 3.4). At forehand this implies that, due to the almost complete absence of Less Favoured Areas, Denmark and the Netherlands will not appear in this analysis.

We assume that major factors influencing the level of farm income are differences in: subsidies, farm size, productivity and prices. There may be interdependencies between the last two factors and the farm size, due to economies of scale. Perhaps bigger farms will be able to get a discount on purchase of a large quantity of inputs and get higher prices for their final products for the same reason. Also they may be able to use their labour and equipment more efficient. But there will also be other factors, which will influence productivity and prices. Productivity will depend also on for instance the quality of the soil, the climate and managerial abilities. Prices may depend on the distance between the farm and related industries.

We will start this chapter with a description of definitions of variables (1.2) and the method of investigation (1.3).

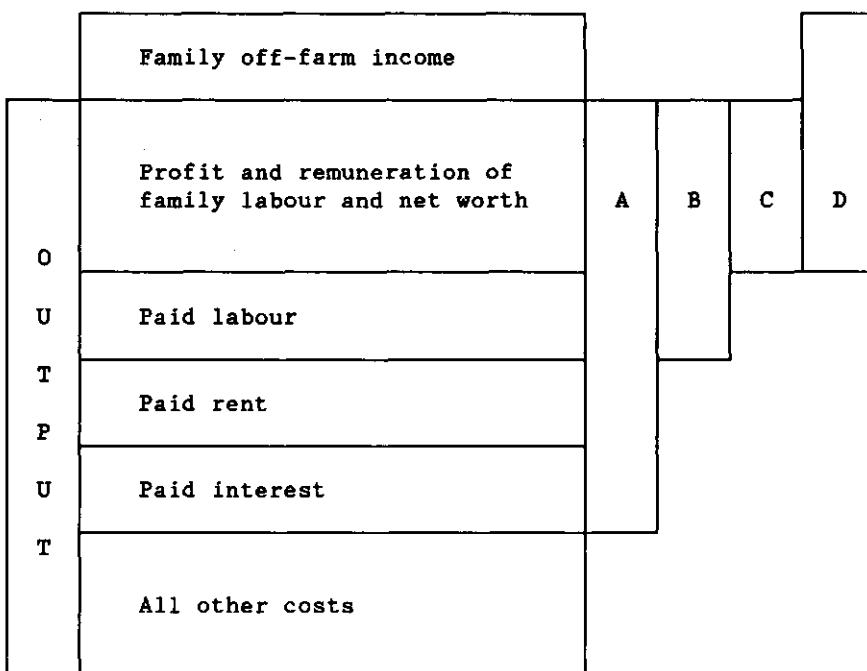

### 1.2 Defining the indicators

Relationships between income, size, productivity and prices are quite complex. With use of the data from the FADN we will try to describe these factors, and as far as possible analyze relationships between them. Before describing the methodology however, we will first describe the data which have been used. Reason for doing so is, that the kind of data available from FADN, will put restrictions on the kind of analysis to be carried out. Some of the key figures are computed from the original data. The definitions of these computed variables are presented in annex 1.

In the introduction there appeared to be five items to be studied: a) income, b) subsidies, c) farm size, d) productivity, and e) prices. Several indicators can be used to represent these items. A short description will be given of the indicators used in this chapter.

a) Income

There are several concepts of income (figure 2.1):

A = Farm net value added

B = Farm income

C = Family farm income

D = Total family income

*Figure 2.1 Composition of different concepts of income*

The income indicator to be chosen, has to give relevant information about the possibilities of permanency of the farm. In this respect the farm net value added per farm or per worker gives no adequate information. The value added indicates the size of the farm and the importance of the farm in generating income, which is more useful to assess the role of agriculture for the regional or national economy. Here, total family income of the farm household should be looked at. However, the FADN contains no data on off-farm income so we can only consider family farm income. Given the fact that the amount of family labour differs from farm to farm, we will use the family farm income per family work unit as the main income indicator.

In the analysis one should keep in mind, that low family farm income does not necessarily have to mean low income! In regions with part-time farming there may be other sources of income.

b) Subsidies

We may consider income with and without subsidies. When analyzing the reasons for differences in income, income without subsidies is taken into consideration. We follow this course because we want to investigate the role of productivity and prices in explaining income differences.

Yet, we do have to bear in mind that apart from the directly paid subsidies, other forms of indirect subsidization will influence

level of income. Firstly, an important share of indirect subsidization arises from the CAP's price support. In chapter 6 of the first volume we will go into this matter. Secondly, subsidization by means of special tax regulations or social security regulations is not taken into account. Information on these items is hard to obtain.

An evaluation of the effects of (direct) subsidization in diminishing income differences between farms in Less Favoured Areas and in normal areas will also be made. These direct subsidies arise from different policies. Apart from the LFA regulations, there are other programs from the EC orientation section, premiums from the guarantee section and several national policies.

If we take a look at the disbursements from the Orientation Fund, it appears that in 1985 some 400 million ECU was spent. Almost 60% of this budget was directed towards action for Less Favoured Areas. Half of this 60% is spent on compensatory payments, while the rest is used for specific actions in certain areas. The rest of the budget of the Orientation Fund is divided in general socio-structural actions (25% of the budget, mainly for investment plans) and disbursements related to market regulations (14% of the budget).

Regarding the Guarantee Fund, most disbursements are directed towards price support. Yet, one specific measure has to be mentioned. For sheep, support is given by means of the ewe premium. Moreover, there is a special market regime in the United Kingdom. Prices for sheep are lower here than in the rest of the EC. By means of a so called variable slaughter premium farmers are compensated. All of these premiums are included in the subsidies from the FADN, and are - especially for the United Kingdom - quite high.

This bunch of policies will lead to interregional differences in the level of subsidization. In 1985 however, only 27% of all farms in Less Favoured regions received subsidies on the basis of the LFA directive. So in some regions or even countries, there hardly may be expected any significant differences with farms in normal areas.

c) Farm size

In the FADN farms are classified by the European Size Unit (ESU), of which the shortcomings for this study already have been mentioned in chapter 1 (1.3) of the first volume. Instead we will use farm net value added (subsidies excluded), defined as the value of the difference between total output on the one hand and (crop or livestock) specific costs, overhead costs, depreciation costs, investment grants and subsidies and current grants and taxes on the other hand.

d) Productivity

Differences in family farm income (excluding subsidies!) per family worker may be caused by differences in productivity. Theoretically, net productivity defined as net production per unit of factor costs should be used. However, that would necessitate a great number of data on a number of items such as prices and volumes per unit of production and of input. Because these data are only partly available from the FADN, other variables to indicate productivity have to be used.

The choice of a certain indicator will also depend on the kind of farming type. When only one main product is produced (e.g. milk for dairy farming), it is easier to give productivity figures for a farm than for farming types with many different final products and production methods (e.g. permanent crop holdings).

Therefore we have to lower our aspirations and use different indicators for productivity, partly depending on the farming type. In general terms the following indicators will be used.

a) Indicators for land productivity:

- gross margins per hectare;
- yields per hectare or animal;
- production plan.

The first indicator, gross margin per hectare, is used to reflect productivity per hectare for the whole set of farm activities. This is helpful if a comparison must be made between for instance, a farm in a normal area which produces mainly potatoes and a farm in a Less Favoured Area cultivating oilseeds and cereals.

If there are differences in gross margins, there may be two reasons. Firstly, yields per hectare may differ for a crop. Secondly, it may be possible that the share of profitable products in the production plan differs.

b) Indicators for labour productivity:

- farm net value added per work unit and
- acreage per work unit.

The level of the first indicator depends on various factors such as land productivity, climate, economies of scale, management qualities and regional prices. Acreage per work unit will give additional information about labour productivity.

e) Differences in prices

Differences in income may also be caused by differences in price-level for inputs and for final products. Cheaper input prices can be caused by several factors such as an advantage in geographical location, a bigger farm size, a better developed infrastructure and/or a well developed agri-industry. Differences in the proceeds are due to the same factors and also to the relations with the consumers market. The FADN is very chary in giving information on prices. With respect to prices for inputs there is no information at all, while only for some final products unit values can be computed. It is therefore possible to analyse the differences in unit values for some final products and some farming types only. Still, the unit value is not identical to the price, because the production will not always consist of homogeneous products.

### 1.3 Method

For all farming types we will describe the income situation of farms in Less Favoured Areas and possible reasons for income disparities with normal areas. Results will be described for the country as a whole. If there are major differences between regions within a country, they will be mentioned explicitly. Here the main steps of the analysis are described:

- Income situation

Starting point is the income situation of farms in Less Favoured Areas compared to the farms in normal areas per country. As has been mentioned there are no data on off-farm income. Therefore, family farm income per family work unit is the central issue here.

- Subsidies

As our interest lies in the causes for income differences, we start with an investigation of the amount of direct subsidies. This gives some insight in the effectiveness of the LFA regulations.

- Regional income differences

Nextly, we subtract these subsidies from the total family farm income, to get insight in the level of income. We will concentrate on

the income differences between regions within a country. Only regions having more than one thousand farms of a certain farming type in normal or Less Favoured Areas are taken into consideration. The standard deviation of farm income between regions will be used as a yardstick to indicate the level of regional income differences.

- Reasons for income differences

Farm size will generally be positively correlated with farm income (excluding subsidies). However, with that knowledge we still do not know the underlying reasons for these size differences.

Size differences may be caused by differences in scale, but it can also be an expression of worse production circumstances or a combination of both. Some indicators will be used to shed some light on this question.

Characteristics giving an indication of productivity per hectare or animal will be considered first. Our assumption is that a lower productivity reflects the existence of unfavourable production circumstances (natural handicaps, but also educational, infrastructural etc.).

In addition, labour productivity is regarded. Whereas productivity per hectare focuses on land productivity, indicators of labour productivity will be used to gain insight in the scale of farming operations. We assume that, given an equal land productivity, a lower labour productivity is mainly a problem of scale.

Furthermore, locational aspects might differ, which causes differences in prices for inputs and/or final products due to variations in regional circumstances such as the distance to the market, the infrastructure and the development of the agri-industry. Only a limited amount of data is available on this point. For a limited number of products only, unit values of final products can be computed from FADN. Moreover, these final products do not have to be homogeneous. So differences in final prices as computed here, do not only reflect market circumstances, but also differences in product quality and the state of processing of a product.

## 2. CEREAL FARMS

### Location and number of farms

The FADN represents over 200,000 specialized cereal farms, a third of which is located in Less Favoured Areas. In proportion to the total number of farms in Less Favoured Areas, four percent falls under the heading "cereal farms". Most cereal farms in Less Favoured Areas are located in Italy (Mountain areas 32%, other Less Favoured Areas 30%), Greece (17% in other Less Favoured Areas, 5% in Mountain areas) and France (12%) (table 2.1).

### Farm income

Differences in family farm income per family worker between normal and Less Favoured Areas are very high in France. Here, income in normal areas is nearly twice as high (+6400 ECU) as in the Less Favoured Areas (table 2.1). Within the French Less Favoured Areas income is very low in the Mountain Areas. In the other countries income in normal areas is also higher, but differences with Less Favoured Areas are smaller (Italy +1200 ECU, Greece +800 ECU). Within the Less Favoured Areas in these countries, farm income in Mountain areas is a little lower than in other Less Favoured Areas. When comparing farm income (in PPS and in ECU) in Less Favoured Areas between countries, differences appear to be rather small.

For all countries, the number of family work units per farm is more or less the same in normal and Less Favoured Areas, so for the total family farm income, differences between normal and Less Favoured Areas are of the same magnitude as described above.

Mountain	5700	6329	7135	697	5144
other LFA	6172	6913	7024	740	5522

## Subsidies

In all three countries, the amount of subsidies for farms in Less Favoured Areas is only slightly higher than in normal areas. Only in the Mountain areas of France - with very low incomes - subsidies are relatively high. Still, the income gap is narrowed to a small extent only.

## Regional income differences

In France, most farms in Less Favoured Areas are located in two southern regions (Aquitaine and Midi-Pyrénées; for regional data see tables A.2.1 to A.2.3 in annex 2), whereas farms in the normal areas are mainly located in the northern and central parts of France, the traditional cereal producing regions. By means of the standard deviation of income between regions per type of area, we get information about regional differences. For normal areas this standard deviation of income (excluding subsidies) per family worker amounts 4000 ECU. Given a difference in income of 6000 ECU between normal and Less Favoured Areas, this means that there will be hardly any normal areas with an income below the average income of farms in Less Favoured Areas. It appears that only in Aquitaine income in normal areas is very low, even lower than income in the Less Favoured Areas of this region.

In Italy, the differences in income between regions are relatively low for Mountain areas (0-1000 ECU), whereas they are higher for other Less Favoured (0-3300 ECU) and normal areas (0-3100 ECU). Because the difference in average income between normal and Less Favoured Areas is not very high (1300 ECU), this entails that for some regions income in normal areas will be lower than in some Less Favoured Areas and vice versa. In Veneto, Toscana, Marche, Umbria and Puglia, income in normal areas lies below the average income of Less Favoured Areas. Whereas in the Less Favoured Areas of Veneto, Toscana and Puglia income lies at or even above the average of all Italian farms in normal areas!

Finally, in Greece the regional differences are low for normal areas (0-1000 ECU), whilst most farms in Less Favoured Areas are concentrated in one region only (Makedonia). Although differences in income are low, the average income for farms in all normal areas lies above income in Less Favoured Areas.

## Reasons for income differences

Looking at the farm characteristics, French farms appear to be larger than those in Greece and Italy (table 2.2). Average acreage is three times as big, whereas labour input per hectare is far lower. Also, differences in income between farms in normal and Less Favoured Areas are larger in France than in Greece and Italy.

In France, the main reason for the larger farm size of farms in normal areas is their larger acreage in comparison with farms in Less Favoured Areas (62 against 46 hectare). Moreover, the hectare output in the normal areas is also a little higher (+70 ECU) while direct costs are the same as in Less Favoured Areas. Despite the small differences in hectare output, yields per hectare appear to be substantially higher in normal areas, whereas prices per unit of production are also a little higher (table 2.4).

It appears that the higher output per hectare from arable crops in normal areas gets partly compensated by a different production plan. In the Less Favoured Areas the percentage of forage crops is higher, with a probably higher output from livestock production. Finally, the labour input per hectare is substantially lower in normal areas than in Less Favoured Areas. So, on farms in normal areas output per hectare is higher whereas it takes less labour to produce that output.

In Italy and Greece farms are considerably smaller than in France. In both countries farm size is larger in normal areas, as counts for income. Yet, whereas correlation between income and size is high ( $R^2=0.85$ ) in Italy, for Greece correlation appears to be rather low ( $R^2=0.52$ ). The main reason for the smaller farm size in the Less Favoured Areas of Italy is a smaller hectare output. In these areas gross margin per hectare is 390 ECU lower than on farms in normal areas. The lower outputs are caused by lower yields per crop, but also by a higher percentage of forage crops in the cropping plan.

*Table 2.4 Yields per hectare and prices of arable crops of cereal farms*

mountain	30	23	28	21.2	29.5	20.8
other LFA	42	26	37	18.5	27.4	17.5

In Greece the difference in gross margin per hectare (510 ECU) is even larger than in Italy. The higher yields per hectare, especially for durum wheat, and the higher price for cereals in normal areas seem to be the most important reasons for the higher gross margin. The cropping plan does not differ very much. The higher hectare output is partly compensated by a larger acreage in the Less Favoured Areas (+80%) and a lower labour input per hectare.

#### Conclusions

In France the income difference between normal and Less Favoured Areas is quite large, whereas it is rather small in Greece and Italy. Subsidies do not narrow this income gap substantially in either country.

In France, the reason for the income differences mainly seems to be caused by differences in acreage, with a lower labour productivity (in terms of labour input per hectare) in the Less Favoured Areas. The higher yields of arable crops in normal areas indicate better production circumstances in these areas than in Less Favoured areas. In Less Favoured Areas a higher share of livestock production partly compensates the lower output from arable production.

In Italy and Greece the higher output per hectare in normal areas, indicate that worse production circumstances in Less Favoured Areas may play a role in the lower incomes.

### 3. GENERAL CROPPING FARMS

#### Location and number of farms

Farms represented under "general cropping farms" cover a mixture of arable farming types, that are not specialized in cereal production. Although the emphasis lies on arable cropping, also other activities such as livestock raising, viticulture and horticulture occur.

From a total of 820,000 farms that are represented by the FADN, more than 60% is located in normal areas, 20% in other Less Favoured Areas and 18% in Mountain areas. Comparing the production plan between farms in normal and Less Favoured Areas, there appear to be no significant differences (table 3.4). Regarding the division of farms in Less Favoured Areas over the member states, far the greatest part is located in Italy (54%) and Greece (36%), whereas in France (8%) and Germany (1%) the number of farms is far lower (table 3.1). The other countries have been left out consideration because there is only a very low number of farms of this farming type in Less Favoured Areas.

#### Farm income

Family farm income per family work unit is considerably higher in normal areas in West Germany (+7100 ECU) and France (+4700 ECU) than in

their Less Favoured Areas. These income differences are smaller in Italy (+1500 ECU) and Greece (+1200 ECU) (table 3.1). Within the Less Favoured Areas, income on farms in Mountain areas of Italy is below that of other Less Favoured Areas, in Greece income is equal, whereas in France the opposite holds. Comparing income (in PPS and ECU) of Less Favoured Areas between countries, it appears to be lowest in West Germany.

The amount of family labour does not differ very much between Less Favoured and normal areas. Therefore, the same conclusions with respect to income differences hold when the total family farm income is considered.

#### Subsidies

The fact that income differences between normal and Less Favoured Areas in Italy and Greece are relatively small, is not caused by higher subsidies for farms in Less Favoured Areas: the average amount of subsidies is quite low for all farms in these countries. In West Germany and France the level of subsidies is higher, but only in France there is a pronounced difference between Less Favoured and normal areas. Still, only a small part of the income gap is narrowed by subsidies in France.

#### Regional income differences

In West Germany the differences in the level of income between regions is rather high for normal areas ( $\delta=4300$  ECU). It appears that income (excluding subsidies) is generally lower in the southern regions of

West Germany. Regarding the Less Favoured Areas, almost all of them are located in the south (Bayern). Within Bayern, the income gap between normal and Less Favoured Areas is only a third of the national figure (see annex 3 table A.3.1).

In France, regional differences in income are a little higher in normal areas ( $\text{G}=4000$  ECU) than in Less Favoured Areas ( $\text{G}=3400$  ECU). Rather high is the income in the Less Favoured Areas of Centre, where the average income is almost as high as in the normal areas of France. Still, most general cropping farms in Less Favoured Areas are located in the south, especially Aquitaine and Midi-Pyrenees. Within these regions income in the Less Favoured Areas is low.

In Italy, regional differences in income are smaller than in France, as well in Less Favoured Areas ( $\text{G}=1800$  ECU) as in normal areas ( $\text{G}=2200$ ). Given the relatively low income differences between normal and Less Favoured Areas, these standard deviations indicate that part of the Less Favoured Areas will have higher incomes than in normal areas. Their appears to be no clear geographical pattern. In the south of Italy for instance, income is relatively low in the normal areas of Abruzzi, whereas farm income is relatively high in the normal areas of Sicilia and Sardegna. The same holds for the other parts of Italy, with for instance high incomes for both normal and Less Favoured Areas in Lombardia and Emilia-Romagna and low ones in Piemonte and the normal areas of Liguria.

In Greece finally, differences in income between regions are rather small for both normal and Less Favoured Areas (of respectively 200 and 400 ECU).

#### Reasons for income differences

As can be seen from table 3.2, farms in normal areas are larger than in Less Favoured Areas for all countries. Especially in France and West Germany differences are rather large, as counts for the income differences. There appears to be a high correlation between these two variables. Yet, what we are interested for are the reasons for these size differences.

In West Germany and France the cultivated area is far larger than in Greece and Italy, whereas labour input per hectare is lower. Because of these differences we will describe these groups of countries separately.

Differences in size may be related to differences in acreage and in productivity per hectare. The acreage per farm is larger in normal areas of both France (+10 ha) and West Germany (+8 ha). The output per hectare is also higher in normal areas compared to Less Favoured Areas for these two countries. In France this higher output is partly caused by a higher use of inputs such as fertilizers and chemicals. But even after subtracting these costs from the total output there remain big differences in gross margin per hectare (270 ECU). In West Germany differences in gross margin per hectare are larger (410 ECU).

The higher output per hectare in normal areas is partly caused by higher yields for most crops, whereas prices per unit of output do not differ very much between normal and Less Favoured Areas (table 3.3). A second reason for the higher output is a higher percentage of root crops (with high output) and a lower share of less profitable forage crops in the cropping plan in normal areas compared with the Less Favoured Areas (table 3.4).

Finally, the use of labour per hectare is a little higher in Less Favoured Areas than in normal areas. So in Less Favoured Areas more labour per hectare is needed to produce a smaller gross margin.

\*) The price of the crop with the largest acreage is presented (durum or common wheat).

In Italy and Greece, differences in farm size between normal and Less Favoured Areas are far smaller, as is the case with income. The size differences are mainly caused by differences in hectare productivity. Per hectare, output is higher in normal areas of both countries. Again this is partly caused by a higher use of inputs, but the gross margin is still considerably higher in normal than in Less Favoured Areas (Italy +350 ECU, Greece +500 ECU).

Only for some crops (cereals), the higher output per hectare corresponds with a higher yield, whereas for root crops there appear to be only minor differences. The price per unit of production does not differ significantly between normal and Less Favoured Areas. Only in Greece the price of wheat is considerably higher in normal areas. This however, is caused by the fact that in normal areas the price of durum wheat is presented and in Less Favoured Areas the price of the lower priced common wheat. Part of the explanation for the higher output per hectare lies in a higher share of root crops and a lower share of forage crops in the cropping plan of normal areas.

There are no big differences in the acreage per farm. Only in the Mountain areas of Italy farms have a slightly smaller acreage than in normal areas, whereas farms in other Less Favoured Areas have a slightly larger acreage (+ 1 hectare). Given an equal input of labour, this means that labour input per hectare is a little lower in the other Less Favoured areas, even lower than in the normal areas. In Greece finally, there are no significant differences in the amount of labour needed per hectare between normal and Less Favoured Areas.

#### Conclusions

In France and West Germany, income differences between normal and Less Favoured Areas are quite high, whereas they are low in Greece and Italy. Only in France subsidies are a little higher in Less Favoured Areas, but these are only enough to narrow the gap partly.

The reasons for the income differences in France and West Germany are twofold: a larger acreage and a higher hectare output caused by a higher degree of specialization. In Greece and Italy the difference in hectare output seems to be the major explaining factor. In Greece and Italy this is caused by higher yields, whereas in Italy the higher percentage of arable crops in the cropping plan is an additional factor.

For all countries the lower hectare output in Less Favoured Areas indicates worse production circumstances, whereas in France and West Germany also the lower acreage per worker causes the lower incomes.

#### 4. HORTICULTURAL HOLDINGS

##### Location and number of farms

In the period 1984-1986 there were 85,000 horticultural holdings in EC-10 represented in FADN (table 4.1), of which 75% in normal areas and 25% in Less Favoured Areas (14% in Mountain areas and 11% in other Less Favoured Areas). Nearly all horticultural holdings in Less Favoured Areas are located in Italy (79%) and Greece (17%). In the Less Favoured Areas in the other member states there hardly are any horticultural holdings and therefore these countries are left out of consideration.

##### Farm income

In Italy family farm income per family work unit in normal areas is clearly higher than in Less Favoured Areas (+2300 ECU) (table 4.1), whereas in Greece this difference is small. In both Italy and Greece the amount of family labour input in normal areas is nearly the same as in Less Favoured Areas. So the same conclusions regarding the family farm income per family work unit hold for the family farm income.

##### Subsidies

The amount of received subsidies in other Less Favoured Areas in Italy is some higher than in the other Italian areas, due to higher investment subsidies. In Greece there hardly are any differences in the amount of subsidies between normal areas and Less Favoured Areas.

other LFA	7846	8890	15180	765	7450

##### Regional income differences

In the normal areas in Italy regional differences in family farm income (excluding subsidies) per family work unit are very small ( $\sigma=160$

ECU; (FFI-subs)/FWU=10100 ECU) 1), while these differences are larger in the Less Favoured Areas (G=1320 ECU; (FFI-subs)/FWU=7600 ECU). The income in the normal areas in Veneto, Liguria and Toscana is lower than the average income in the Italian Less Favoured Areas (table 4.1 and annex 4 table A.4.1). In the Less Favoured Areas in Toscana, income is very high; even higher than the average income in Italian normal areas.

While income differences between the Greek normal areas and Less Favoured Areas are small, there are regional differences in the normal areas (G=1270 ECU; (FFI-subs)/FWU=6600 ECU). The income in the normal areas in Makedonia Thraki and Ipeiros Peloponnisos Nissi Ioniou is even lower than the average income in Greek Less Favoured Areas.

#### Reasons for income differences

In Italy and Greece the farm size in Less Favoured Areas is smaller than in normal areas, as is the case for income, which is lower in Less Favoured Areas (table 4.2 and annex 4 table A.4.2). But in Greece, the differences are very small. The results of correlation analysis corroborate the conclusion that there is a strong relation between farm income and farm size (Italy R<sup>2</sup>=0.96; Greece R<sup>2</sup>=0.95).

One of the reasons for the smaller size of horticultural holdings in the Italian Less Favoured Areas is the smaller agricultural area. Besides, the labour input per hectare is higher in the Less Favoured Areas. Contrary however, the output and gross margin per hectare in Less Favoured Areas are higher than in normal areas.

While the size of horticultural holdings in the Greek Less Favoured Areas is nearly the same as in normal areas, the agricultural area is about 30% larger in Less Favoured Areas. Contrary, the output per hectare

other LFA	36	21	12	2	2	90	28	34	5	20

in Less Favoured Areas is some 20% lower than in normal areas. Regarding crops separately however, the output per hectare of vegetables is only 10% lower in these areas (table 4.3 and annex 4 table A.4.3). So the lower average output per hectare is partly due to the smaller share of vegetables and non-perennial fruit in the cropping plan (table 4.4 and annex 4 table A.4.4). The gross margin per hectare also is lower in Less Favoured

Areas. But this difference is smaller than the difference in output per hectare, because the costs per hectare are lower in Less Favoured Areas. The amount of labour input per hectare in Less Favoured Areas is lower than in normal areas. This may be explained by the smaller share of intensive vegetables and non-perennial fruit in the cropping plan of horticultural holdings in Less Favoured Areas.

#### Conclusions

The incomes of horticultural holdings in Less Favoured Areas are lower than in normal areas, especially in Italy. The small amount of received subsidies does not lead to another income situation.

The size of the farm is an explaining factor regarding the income level: the larger farms in normal areas have a higher income than the smaller ones in Less Favoured Areas. In Italy, the gross margin per hectare is higher on the holdings in Less Favoured Areas. The lower incomes in the Italian Less Favoured Areas are generally caused by a smaller surface of agricultural area and a lower labour productivity. In Greece, the incomes in Less Favoured Areas are nearly the same as in normal areas. The surface of agricultural area is some larger in Less Favoured Areas. But the share of profitable vegetables in the cropping plan and the output per hectare are lower in these areas, compared with the normal areas. The last mentioned aspects might be caused by natural restrictions.

## 5. VINEYARDS

### Location and number of farms

Over 180,000 vineyards in EC-10 are represented in FADN (table 5.1), of which 72% in normal areas and 28% in Less Favoured Areas (19% in Mountain areas and 9% in other Less Favoured Areas). Far the greatest part of the vineyards in Less Favoured Areas is found in Italy (60%) and Greece (29%). Except for these countries, there also are vineyards located in the Less Favoured Areas in France (8%) and West Germany (3%). In the other member states there hardly are any vineyards at all and therefore they are left out of consideration.

### Farm income

In France, family farm income per family work unit in Less Favoured Areas is much lower (-5600 ECU) than in normal areas (table 5.1). Within the Less Favoured Areas the income in the mountainous part is relatively quite good; 3000 ECU above the average income in the French Less Favoured Areas. In the other countries income differences between normal areas and Less Favoured Areas are less than 1000 ECU. Remarkable is the fact that in Italy and, to a lesser degree, West Germany the incomes in Less Favoured Areas are higher than in normal areas. A reason for the small income differences between Less Favoured Areas and normal areas in West Germany

*Table 5.1 Income and other characteristics of vineyards*

other LFA	6676	7493	8722	621	6201

might be the fact that the vineyards in West German Less Favoured Areas are only called less favoured, because more than 50% of their acreage (e.g. forage and arable crops) is situated in the less favoured part of the holding. But probably this is not quite justified, because the acreage vineyard is located in the normal part. So, for this reason West Germany is not analyzed in the subsection "reasons of income differences".

In West Germany, Italy and Greece the input of family labour in normal areas is nearly the same as in Less Favoured Areas. However in France, family labour input is some higher in Less Favoured Areas, which results in smaller differences in family farm income between normal areas and Less Favoured Areas, compared with the differences in family farm income per family work unit. In the French Mountain areas the family farm income is even higher than in normal areas.

#### Subsidies

In the Less Favoured Areas in West Germany and in the Mountain areas in France and, to a lesser degree, Greece the amount of received subsidies is higher than in the normal areas in these countries (table 5.1). In the French and Greek other Less Favoured Areas the situation is opposite. The received subsidies in Italy are very low and nearly do not have any influence on the income differences between normal areas and Less Favoured Areas.

#### Regional income differences

Most French vineyards are located in normal areas. Here, regional differences in family farm income (excluding subsidies) per family work unit are very large ( $0=8280$  ECU; (FFI-subs)/FWU= $17400$  ECU). High incomes are reached in Champagne-Ardenne, Rhone-Alpes and especially Bourgogne. However, in Languedoc-Roussillon, Provence-Alpes-Cotes d'Azur and Poitou-Charentes they are lower than the average income in the French Mountain areas (table 5.1 and annex 5 table A.5.1). Only in Aquitaine and Rhone-Alpes there are vineyards located in Less Favoured Areas. In the Less Favoured Areas in Aquitaine, income is lowest of all French areas. But in Rhone-Alpes income in Less Favoured Areas is even higher than in some French normal areas with relatively low incomes.

In the normal areas in Italy, where income is generally lower than in Less Favoured Areas, regional income differences are relatively small ( $0=1550$  ECU; (FFI-subs)/FWU= $5900$  ECU), with low incomes in Campania and Piemonte. Contrary however, in Less Favoured Areas differences are very large ( $0=4180$  ECU; (FFI-subs)/FWU= $6600$  ECU). Income is high in the Less Favoured Areas in Veneto and Puglia, whereas income in the Less Favoured Areas in Lombardia, Abruzzi and Toscana is even much lower than the average income in Italian normal areas.

Between the two Greek regions with vineyards in normal areas there hardly are any income differences, while differences are larger in Less Favoured Areas ( $0=1150$  ECU; (FFI-subs)/FWU= $4900$  ECU). The income in the Less Favoured Areas in Makedonia Thraki is even higher than the average income in Greek normal areas.

#### Reasons for income differences

In France and Greece the size of vineyards in Less Favoured Areas is smaller than in normal areas, while the incomes are lower (table 5.2 and annex 5 table A.5.2). In Italy the situation is the opposite: larger farms with higher incomes in the Less Favoured Areas. The results of correlation analysis corroborate the conclusion that there is a strong relation between income and size of vineyards (France  $R^2=0.84$ ; Italy  $R^2=0.76$ ; Greece  $R^2=0.90$ ).

The average size of vineyards in France is large, compared with the other investigated countries. Within France, one of the reasons for the smaller size of vineyards in Less Favoured Areas is the lower output per hectare in these areas. Regarding crops separately, the output per hectare vineyard in other Less Favoured Areas also is lower than in normal areas, whereas it is higher in French Mountain areas 1). As is the case for the output per hectare, the gross margin per hectare is lower in Less Favoured Areas. Because the fixed costs per hectare in Less Favoured Areas are nearly half as high as in normal areas, especially through lower external factor costs, differences in family farm income - excluding subsidies and taxes - per hectare between other Less Favoured Areas and normal areas are smaller, whereas family farm income - excluding subsidies and taxes - per hectare in Mountain areas is even higher than in normal areas. The share of vineyards (with a high output per hectare) in the cropping plan in Less Favoured Areas is much smaller (-26%) than in normal areas, while the share of forage crops is much higher. Notwithstanding the lower share of intensive crops in the cropping plan in Less Favoured Areas, the labour input per hectare in these areas is nearly the same as in normal areas.

Regarding the agricultural area there is no difference between normal and Mountain areas in Italy. Explaining factors for the larger size of

1) Differences in the output of wine and grapes per hectare vineyard could be partly caused by differences between quality wine, other wine and table grapes. Data about these parts were not available.

vineyards in Mountain areas are the higher output and gross margin per hectare in these areas. The share of vineyard in the cropping plan and the labour input per hectare in Mountain areas are nearly the same as in normal areas. In the other Less Favoured Areas, where however only a small part of the vineyards is located, the larger agricultural area could be a reason for the fact that the size of vineyards in these areas is larger than in normal areas. The output and gross margin per hectare in the other Less Favoured Areas are lower than in normal areas. This could be caused by the lower share of vineyard and the higher share of forage crops in the cropping plan in these areas. The lower labour input per hectare in other Less Favoured Areas is probably caused by the higher share of extensive forage crops in the cropping plan.

Reasons for the smaller size of vineyards in the Greek Mountain areas, compared with the normal areas, are the smaller agricultural area, the lower output and gross margin per hectare, and the lower share of vineyard in the cropping plan. Besides, the labour input per hectare is higher in Mountain areas. In contrast with the Mountain areas, the output and gross margin per hectare and the share of vineyard in the cropping plan in the other Less Favoured Areas are higher than in normal areas. Nevertheless, income of vineyards in other Less Favoured Areas is lower than in normal areas, as is the case for Mountain areas.

## **Conclusions**

The picture of the income situation on vineyards differs from that of the most other farming types: income of vineyards in Less Favoured Areas is not generally lower than in normal areas. In Italy, income in Less Favoured Areas is even higher than in normal areas.

The size of vineyards is an explaining factor regarding the income level: larger vineyards in both normal areas and Less Favoured Areas reach a higher income. The gross margin per hectare in Less Favoured Areas is not generally worse than in normal areas. Lower incomes on vineyards in Less Favoured Areas are caused by a smaller agricultural area and/or a smaller share of vineyard in the cropping plan. The last mentioned aspect might be caused by natural restrictions or quota systems for quality wine.

## 6. PERMANENT CROP HOLDINGS

### Location and number of farms

This chapter describes the permanent crop holdings, which consist of three subtypes of holdings:

- specialist fruit and citrus fruit,
- specialist olives and
- various permanent crops combined.

In the EC-10, there are about 400,000 permanent crop holdings represented in FADN (table 6.1), of which 54% in normal areas and 46% in Less Favoured Areas (29% in Mountain areas and 17% in other Less Favoured Areas). Nearly all permanent crop holdings in Less Favoured Areas are located in Italy (61%) and Greece (38%). In most other member states there only are permanent crop holdings located in normal areas, except for France. However, the number of permanent crop holdings in the French Less Favoured Areas is very small.

### Farm income

In Italy and Greece, family farm income per family work unit in the Less Favoured Areas is nearly 25% lower than in normal areas (table 6.1). The input of family labour in these countries does not differ between normal areas and Less Favoured Areas. So, the above mentioned conclusion holds also for the family farm income.

### Subsidies

The amount of received subsidies in the Greek Less Favoured Areas and in the other Less Favoured Areas in Italy is some higher than in the normal areas in these countries, while they are almost equal in the Italian Mountain areas.

other LFA	5588	6825	7396	839	4954	67875

### Regional income differences

The income situation in the Italian regions is quite divergent (table 6.1 and annex 6 table A.6.1) in normal areas (G=1860 ECU; (FFI-subs)/FWU=7100 ECU) as well as in Less Favoured Areas (G=1880 ECU; (FFI-subs)/FWU=5400 ECU). In the normal areas in Veneto and Emilia-Romagna, family farm income (excluding subsidies) per family work unit is very high, whereas income in the normal areas in Piemonte, Abruzzi and Puglia is even lower than the average national income in Less Favoured Areas. Income in the Less Favoured Areas in Trentino and, especially, Sardegna is higher than the average national income in normal areas, while income in the Less Favoured Areas in Piemonte and Liguria is very low. Apart from the income differences, there also are a few Italian regions with very high subsidies: the Mountain areas in Toscana and the Less Favoured Areas in Puglia.

In the Greek normal areas, there are some income differences between regions (G=1160 ECU; (FFI-subs)/FWU=5500 ECU). Especially in the normal areas in Thessalia, income is high. In the Less Favoured Areas in Greece, there hardly are regional income differences (G=80 ECU; (FFI-subs)/FWU=3900 ECU).

### Reasons for income differences

In both investigated countries, the size of permanent crop holdings in Less Favoured Areas is smaller than in normal areas, as is the case for income, which is lower in Less Favoured Areas (table 6.2 and annex 6 table A.6.2). The results of correlation analysis corroborate this conclusion about the relation between income and size of permanent crop holdings (Italy R<sup>2</sup>=0.81; Greece R<sup>2</sup>=0.96).

Reasons for the smaller size of permanent crop holdings in the Less Favoured Areas in Italy and in Greece are the lower output and gross margin per hectare in these areas. The lower output per hectare is partly caused by the higher share of crops with a relatively low output per hectare (olive groves in Italy and Greece and forage crops in Italy) in the

cropping plan in Less Favoured Areas (tables 6.3 and 6.4 and annex 6 tables A.6.3 and A.6.4). Regarding the agricultural area and the labour input per hectare, in Italy, differences between Less Favoured Areas and normal areas are very small. However in Greece, the agricultural area in Less Favoured Areas is some larger than in normal areas, while the labour input per hectare is lower in the Greek Less Favoured Areas.

### **Conclusions**

The income of permanent crop holdings in Less Favoured Areas is lower than in normal areas. The size of the holding is an explaining factor for this income differences. Reasons for the smaller size of permanent crop holdings in Less Favoured Areas are the relatively low output per hectare and the higher share of crops with a low output per hectare in the cropping plan in Less Favoured Areas.

## 7. DAIRY FARMS

### Location and number of farms

Regarding the Less Favoured Areas, specialized dairy farms (183,500) are mainly located in the Mountain areas of Italy (22%), in France (Mountain areas 11%, other Less Favoured Areas 10%), in West Germany (other Less Favoured 25%, Mountain areas 6%) and in Ireland (16%). Furthermore, a relatively low percentage of farms is located in the United Kingdom (4%) and Belgium (3%) (table 7.1). The share of milk and milk products in the total output lies in between 55% in Italy and 72% in the United Kingdom. Next to dairying, beef production is the most important activity on these farms.

### Farm income

Farm income per family worker is far higher in the normal areas of Italy (+5900 ECU) and Ireland (+5000 ECU), compared with their respective Less Favoured Areas (table 7.1). In France, West Germany, Belgium and the United Kingdom these differences are lower (about 2000 ECU). Within West Germany, farm income in Mountain areas is considerably lower than in other Less Favoured Areas. In absolute terms income (in ECU and PPS) in Less Favoured Areas is relatively high in Belgium and the United Kingdom.

In Italy, and to a smaller extent Ireland, the amount of family labour is higher in normal areas. So, differences in total family farm income are even higher here.

### Subsidies

In the United Kingdom farms in Less Favoured Areas receive considerably more subsidies (+3300 ECU) than farms in normal areas. Also in Belgium and France the higher subsidies diminish the income gap significantly. Contrary in Italy and Ireland - having the highest income differences - subsidies do not play a big role in diminishing differences between normal and Less Favoured Areas.

### Regional income differences

In West Germany almost half of all dairy farms are located in Bayern. Regarding the regional differences in farm income (excluding subsidies) we find a standard deviation of 3000 ECU for normal areas and of 4000 ECU for Less Favoured Areas. With a difference in income between normal and Less Favoured Areas of 2400 ECU, this indicates that there will be quite some Less Favoured Areas with higher incomes than in normal areas. Looking at the regional figures it appears that in northern and western regions income is high in both normal and Less Favoured Areas, while it is low in the southern and eastern regions (for regional data see table A.7.1 to A.7.3 of annex 7).

In France most dairy farms in Less Favoured Areas are located in the south, whereas the farms in normal areas are mostly located in northern areas. Income differences between regions are not high (normal areas:  $\sigma=1400$  ECU, Less Favoured Areas:  $\sigma=1230$  ECU), whereas the difference in average income between normal and Less Favoured Areas (3600 ECU) is quite high. This means that most farms in Less Favoured Areas will have lower incomes than farms in normal areas. Only in Aquitaine income in normal areas appears to be almost as low as the average income in Less Favoured Areas.

Far the greatest part of Italian dairy farms are located in northern and central regions. Regionally, income differences are high in normal areas ( $0=6300$  ECU), while they are lower in Less Favoured Areas ( $0=2800$  ECU). Yet, the difference in average income between normal and Less Favoured Areas is also high (6000 ECU). It appears that in both the normal and the Less Favoured Areas of Lombardia and Emilia-Romagna as well as the Less Favoured Areas of Lazio farms have a relatively high income.

In the United Kingdom, income differences between normal and Less Favoured Areas are rather high (4600 ECU), whereas the standard deviation of income between regions is very low for Less Favoured Areas ( $0=700$  ECU) and higher for normal areas ( $0=3000$  ECU). It appears that farms in the normal areas of Scotland and East England have an income which lies around the average of Less Favoured Areas. Besides, the amount of subsidies is very low in these normal areas, whereas it is very high for the Less Favoured Areas (especially for England North, Scotland and Northern Ireland). This implies that in normal areas of Scotland and East England, income including subsidies is worse than in most Less Favoured Areas.

#### Reasons for income differences

Farms in normal areas have a bigger size than in the Less Favoured Areas, especially in Italy, the United Kingdom and Ireland (table 7.2). There appears to be a strong correlation between size and income. Only in the United Kingdom this correlation is a little lower.

Differences in farm size can be caused by differences in acreage and in productivity per hectare. In Italy big differences in output per hectare appear (5600 ECU in normal areas against 2400 ECU in Less Favoured Areas), due to a very high number of cows per hectare in normal areas and - to a smaller extent - a higher milk yield (table 7.3). This high output per hectare in the normal areas of Italy is caused by an intensive way of farming with a high labour input per hectare. On these farms a high percentage of the roughage is purchased from other farms. Regarding the acreage, there are no differences between normal and Less Favoured Areas in Italy. So we may conclude that differences in size are mainly caused by a higher output per hectare. Regarding the price level for cows' milk and

products there are big differences between regions, which may depend on the question if and to what extent the milk is processed into specific products. Within regions there appear no remarkable price differences between normal and Less Favoured Areas.

In the United Kingdom, France and West Germany differences in farm size between normal and Less Favoured Areas are mainly caused by differences in output per hectare. Compared with Italy however, these differences are smaller as is the case with regional differences in the price of cows' milk and products. In two regions in the United Kingdom, Scotland and East England, income in normal areas is low, despite the fact that the farm size is comparable to farms in other normal areas.

In Belgium output per hectare in normal areas is nearly twice as high as in Less Favoured Areas, which is caused by a higher number of cows per hectare and a higher milk yield (and a higher price for cows' milk and products). As in Italy and the United Kingdom, labour input per hectare is higher on farms in the normal areas indicating a rather intensive way of

farming. Contrary to the other countries however, in Belgium acreage of farms is far larger in Less Favoured Areas.

In Ireland finally, the gross margin per hectare is higher in normal areas, due to the higher milk yield and a higher number of livestock units per hectare. Additionally, the acreage per farm is significantly larger in the normal areas.

#### Conclusions

The largest differences in income between normal and Less Favoured Areas appear in Italy and Ireland. In the other countries differences are smaller, which is partly caused by higher subsidies.

In most countries these differences are caused by a higher output per hectare, due to a higher milk yield and more livestock units per hectare. In Ireland a larger acreage in normal areas is an additional reason for a higher income in the normal areas. In Belgium, acreage of farms in Less Favoured Areas is far higher, which partly compensates the lower output per hectare.

So in all countries, production circumstances seem to be worse in Less Favoured Areas, and only in Belgium this is partly compensated by a larger acreage per farm.

## 8. DRYSTOCK FARMS

### Location and number of farms

In the EC-10, 370 thousand drystock farms are represented in FADN (table 8.1), of which 40% in normal areas and 60% in Less Favoured Areas (21% in Mountain areas and 39% in other Less Favoured Areas). The drystock farms in Less Favoured Areas are for the greater part located in France, Italy, Ireland, Greece and the United Kingdom, while there also are some drystock farms in the Less Favoured Areas in West Germany and Belgium.

The drystock farms are a heterogeneous group of agricultural holdings, which consists of three subtypes of farms:

- specialist cattle rearing and fattening,
- cattle dairying, rearing and fattening combined and
- sheep, goats and other grazing livestock.

Other cattle has the greatest share in the livestock population of drystock farms in all investigated countries, except for Greece, where sheep dominate (table 8.4 and annex 8 table A.8.4). Besides, in West Germany, Italy, Belgium and in the normal areas in France dairy cows also have a remarkable share in the livestock population.

### Farm income

In most of the investigated countries family farm income per family work unit in Less Favoured Areas is lower than in normal areas (table 8.1). Especially in Italy, differences are very large (4800 ECU). Contrary however, in Ireland income in Less Favoured Areas is almost equal as in normal areas, whereas in the United Kingdom income in Less Favoured Areas is even much higher than in normal areas.

Because of the lower input of family labour in the Less Favoured Areas in Italy, differences in family farm income between Less Favoured Areas and normal areas are larger than the above mentioned differences in family farm income per family work unit in this country. The higher input of family labour in the Less Favoured Areas in the United Kingdom results in larger differences in family farm income between Less Favoured Areas and normal areas, than the differences in family farm income per family work unit.

### Subsidies

The amount of received subsidies on drystock farms is quite diverse. Generally, farms in Less Favoured Areas receive more subsidies than farms in normal areas. Apart from the differences between normal areas and Less Favoured Areas there also are considerable differences between the member states (table 8.1). Especially in the United Kingdom, Belgium, France and Ireland, the amount of received subsidies is high and differences between Less Favoured Areas and normal areas are large in these countries. On the other hand, the amount of received subsidies in Italy is low. In the United Kingdom, the higher income in Less Favoured Areas is completely due to the received subsidies (14000 ECU), whereas in Ireland, income differences between Less Favoured Areas and normal areas are cancelled by subsidies.

Generally, subsidies received by drystock farmers mainly consist of subsidies on products. But in West Germany and France, drystock farmers also receive subsidies on costs, whereas in France, Italy and the United Kingdom they also receive some investment subsidies.

The high amount of directly received subsidies on drystock farms is partly caused by the EC-policy on these holdings. Examples of these subsidies are the annual ewe premium and the variable premium of the sheep-meat regime and the suckler cow premium of the beef and veal regime. The variable premium scheme, which only operates in Great Britain, might be the reason for the high subsidies in the United Kingdom (and especially the Less Favoured Areas).

#### Regional income differences

In West Germany, differences in family farm income (excluding subsidies) per family work unit between the northern and southern regions are larger than differences between Less Favoured Areas and normal areas (table 8.1 and annex 8 table A.8.1).

The regional income differences in the French Less Favoured Areas are large, compared to the average national income in these areas ( $G=1340$  ECU; (FFI-subs)/FWU=2300 ECU). Income is very low in Poitou-Charentes and Rhone-Alpes, while it is relatively high in Bourgogne. Notwithstanding the large differences in income excluding subsidies between the Less Favoured Areas and normal areas in Poitou-Charentes (-4600 ECU), the subsidies in the Less Favoured Areas are lower than in the normal areas in this region. In the French normal areas, regional income differences are some smaller ( $G=1710$  ECU; (FFI-subs)/FWU=5000 ECU). In Languedoc-Roussillon and Auvergne however, income is lower than the average national income in the French Less Favoured Areas. Because of the high amount of received subsidies in the normal areas in Languedoc-Roussillon, income including subsidies is less worse in these areas.

The regional income differences in the Italian normal areas are very large ( $G=4700$  ECU; (FFI-subs)/FWU=11900 ECU). Income is high in Lombardia and Veneto, while in Campania, income is lower than the average national income in Less Favoured Areas. In the Less Favoured Areas in Italy, there also are large regional income differences ( $G=2170$  ECU; (FFI-subs)/FWU=7000 ECU), with low incomes in Valle d'Aosta, Piemonte, Campania and Basilicata. On the contrary in the Less Favoured Areas in Lombardia and Sardegna, income is relatively good. Apart from the income differences, the drystock farmers in the Less Favoured Areas in Valle d'Aosta and Toscana receive a very high amount of subsidies.

In the United Kingdom there also are large regional income differences in normal areas and in Less Favoured Areas. In the normal areas in East England, income is very low. In the Less Favoured Areas, where the average national income is negative, income in North England is less worse. But, in the Less Favoured Areas in Scotland income is very bad. Because of the very high subsidies, in all regions income including subsidies in Less Favoured Areas is higher than in normal areas.

In Greece, regional income differences are relatively small, as is the case for the national income differences between normal areas and Less Favoured Areas. In the normal areas in Makedonia Thraki and Ipeiros Peloponnisos Nissi Ioniu, income is some lower than the average national income in the Greek Less Favoured Areas, while income in the Less Favoured Areas in Sterea Ellas Nissi Egaeou Kriti is relatively good.

#### Reasons for income differences

In all investigated countries the farm size in Less Favoured Areas is smaller than in normal areas, as is the case for income, which is lower in Less Favoured Areas (table 8.2 and annex 8 table A.8.2). The results of correlation analysis corroborate the conclusion that there is a strong relation between farm income and farm size (in all countries, except for the United Kingdom,  $R^2 > 0.85$ ; United Kingdom  $R^2 = 0.78$ ).

Reasons for the smaller size of drystock farms in Less Favoured Areas are the lower output and gross margin per hectare in these areas. Apart from the generally worse output per livestock unit for the separate products in Less Favoured Areas, the structure of the livestock population has a large influence on the average output per hectare. For example, the output of milk and products per dairy cow is much higher than the output of beef and veal per livestock unit cattle (table 8.3 and table A.8.3). Except for West Germany, the share of dairy cattle in Less Favoured Areas is smaller than in normal areas. The share of sheep in the livestock population in the Less Favoured Areas in all investigated countries, except for Greece and West Germany, is much larger than in the normal areas in these countries.

In some of the investigated countries, the data about the agricultural area and the labour input per hectare are indicative of a more extensive farming system in the Less Favoured Areas. Especially in the

## Conclusions

Family farm income (excluding subsidies) of drystock farms in Less Favoured Areas is generally lower than in normal areas. However, there are large differences between and within countries and regions.

An explaining factor for the lower income in Less Favoured Areas is the smaller size of the drystock farms in these areas, which is caused by the lower output and gross margin per hectare. The structure of the livestock population on drystock farms in Less Favoured Areas is one of the reasons for the lower output per hectare. The share of dairy cows is lower and the share of sheep is larger than in normal areas. This leads to the conclusion that the farming system in Less Favoured Areas is more extensive than in normal areas, probably due to natural restrictions. The fact that the agricultural area in Less Favoured Areas is generally larger than in normal areas, while in more than half of the investigated countries the labour input per hectare in the Less Favoured Areas is lower than in normal areas, also seem to indicate in the direction of a more extensive agriculture.

The effects of the EC and national subsidy policy are considerable. In all member states the received subsidies are higher in the Less Favoured Areas, especially in the United Kingdom. The subsidies on products have the greatest share in the total amount of received subsidies, due to the EC market policy for sheepmeat (and goatmeat) and beef and veal.

## 9. MIXED FARMS

### Location and number of farms

Mixed farming covers farms with a great diversity of agricultural activities, most of which have already been described in the former chapters.

The FADN represents almost 750,000 farms, 62% of which is located in normal areas (table 9.1). The other 38% is equally divided over Mountain and other Less Favoured Areas. Half of all farms in Less Favoured Areas is located in Italy (51%), followed by Greece (21%), France (15%) and West Germany (11%). The other countries only have a very small number of farms in these areas (less than 1%) and will not be described in this chapter.

### Farm income

In all countries family farm income per family work unit is higher in normal than in Less Favoured Areas. The highest difference between normal and Less Favoured Areas occurs in France (3700 ECU), while it is smaller for West Germany (1900 ECU), Italy (1700 ECU) and Greece (900 ECU) (table 9.1). In Italy, income in Mountain areas is lower than in other Less Favoured Areas, whereas in all other countries these differences are very small.

Regarding total family farm income the picture remains about the same. In all countries, the amount of family labour is a little lower in the normal areas compared to the Less Favoured Areas.

### Subsidies

In France and West Germany the average level of subsidies is higher than in Italy (except for some regions: Puglia, Sardegna and the normal areas of Sicilia and Basilicata) and Greece (except for the normal areas of Sterea Ellas Nissi Egaeou Kriti). In these last two countries subsidies in Less Favoured Areas are not higher than in normal areas. In France and West Germany, with higher income differences between normal and Less Favoured Areas, subsidies do reduce the income gap partly.

### Regional income differences

Standard deviation of income (excluding subsidies) between regions in West Germany amounts 2700 ECU for both normal and Less Favoured Areas. Given a difference in average income between normal and Less Favoured Areas of 2400 ECU, some Less Favoured Areas will have higher incomes than normal areas. Again, we notice a lower level of income in the southern and eastern regions, than in the rest of the country. And in Nordrhein Westfalen income on farms in Less Favoured Areas is even higher compared to its normal areas (see table A.9.1 to A.9.4 in annex 9).

In France the standard deviations are a little lower (Mountain and normal areas 1900 ECU, other Less Favoured Areas 1300 ECU), whereas the difference in average income between normal and Less Favoured Areas is higher (4300 ECU). So the division of regions into normal and Less Favoured Areas seems to be reasonable, at least for mixed farming.

In Italy the standard deviation for Mountain (0-1900 ECU) and other Less Favoured Areas (0-1300 ECU) is comparable to France, but for normal areas it is higher (0-2900 ECU). Yet, income differences between normal on the one hand and Mountain and other Less Favoured Areas on the other hand are low (resp. 1800 ECU and 1200 ECU). Given these figures one may

conclude that there will be quite some Less Favoured Areas with a higher farm income than in normal areas. It appears that income in Less Favoured Areas is especially high (above the average income in normal areas) in Lombardia, Veneto, Emilia-Romagna and Sardegna. Oppositely, in Liguria, Umbria, Abruzzi and Calabria income in normal areas lies below the average of Less Favoured Areas.

In Greece finally, standard deviation is very low especially in Mountain areas (300 ECU) and other Less Favoured Areas (400 ECU), but also in normal areas (800 ECU). Still there will be an overlap in income between normal and Less Favoured Areas, because difference in average income only amounts 900 ECU.

#### Reasons for income differences

As has been mentioned already, mixed farms are not very homogeneous when the set of farming activities is compared between countries (table 9.3). The main differences lie in the share of permanent crops, which is higher in Italy and Greece than in France and West Germany. In these last two countries the share of livestock production is higher.

Within these countries there are also differences between farms in normal and Less Favoured Areas. In France and West Germany, farms in normal areas are far larger than farms in Less Favoured Areas (table 9.2). The main explanation for these size differences is the higher gross margin per hectare in normal areas. The higher gross margin can be explained by a higher output per hectare for arable crops and a higher number of livestock units per hectare of forage crops (tables 9.3 and 9.4). Regarding other factors that have an impact on the farm size, acreage and

---

labour input per hectare, there appear no important differences between normal and Less Favoured Areas. Only in France we find that farms in the Mountain areas have a considerable smaller acreage than farms in normal and other Less Favoured Areas. This seems the main explanation for the smaller size of farms in Mountain areas compared with farms in the other Less Favoured Areas of France.

In Italy and Greece the differences in farm size between normal and Less Favoured Areas are smaller. The higher gross margin per hectare in normal areas (Italy: +530 ECU, Greece: +620 ECU) is again the main reason for the size differences. For both countries the higher gross margins are caused by a higher output per hectare. Additionally, in Italy the larger share of vineyards, with high outputs, in the cropping plan of farms in normal areas plays a role. In the other Less Favoured Areas however, especially in Italy, the lower gross margins are partly compensated by a larger acreage and a lower labour input per hectare.

### Conclusions

Income on farms in normal areas in France and, to a smaller extent West Germany, is higher in normal than in Less Favoured Areas, despite higher subsidies in these last areas. In Greece and Italy income differences are lower, but these differences are not diminished by subsidies.

In all countries, differences in income are mainly caused by a lower hectare output on farms in Less Favoured Areas, indicating worse production circumstances. In the other Less Favoured Areas of Greece and Italy, a larger acreage per worker compensates the farms partly for their lower hectare productivity.
