Paper dedicated to Professor O. C. Zienkiewicz

SUMMARY

The characteristic-based split (CBS) stabilization procedure developed originally in fluid mechanics has been adapted successfully to solid mechanics problems. The CBS algorithm has been implemented within a finite element program using an explicit time integration scheme. Volumetric locking of linear triangular and tetrahedral elements has been successfully eliminated. The performance of the numerical algorithm is illustrated with numerical results. Comparisons with an alternative stabilization technique based on the finite calculus method also are given. Copyright © 2006 John Wiley & Sons, Ltd.

KEY WORDS: CBS; volumetric locking; stabilization; dynamic analysis; explicit time integration

1. INTRODUCTION

Many finite elements exhibit the so-called ‘volumetric locking’ in the analysis of incompressible or quasi-incompressible problems in fluid and solid mechanics. Situations of this type are usual in the structural analysis of rubber materials, some geomechanical problems and most bulk metal forming processes. Volumetric locking is an undesirable effect leading to incorrect numerical results [1].

Volumetric locking in solids is present in all low-order elements based on the standard displacement formulation. The use of a mixed formulation or a selective integration technique

eliminates the volumetric locking in many elements. These methods however, fail in some elements such as linear triangles and tetrahedra, due to lack of satisfaction of the Babuška–Brezzi (BB) conditions [1–3] or alternatively the mixed patch test [1, 4, 5] not being passed. Most linear triangular and tetrahedral elements developed within a mixed formulation also suffer volumetric locking. This poses serious limitations on the possibilities of finite element simulation of processes involving large elasto-plastic deformations like metal forming processes. Even nowadays there is hardly any meshing program that can discretize complex three-dimensional geometrical shapes of formed parts avoiding tetrahedral elements. Special stabilizing techniques must be developed to eliminate volumetric locking in linear triangles and tetrahedra.

Considerable efforts have been made in recent years to develop linear triangles and tetrahedra producing correct (stable) results under incompressible situations. Brezzi and Pitkäranta [6] proposed to extend the equation for the volumetric strain rate constraint for Stokes flows by adding a Laplacian of pressure term. A similar method was derived for quasi-incompressible solids by Zienkiewicz and Taylor [1]. Other methods to overcome volumetric locking are based on mixed displacement (or velocity)–pressure formulations using the Galerkin-least-square (GLS) method [7], average nodal pressure and average nodal deformation techniques [8, 9], and sub-grid scale (SGS) methods [10–12] and the approach based on the finite calculus (FIC) formulation [13, 14].

The characteristic-based split (CBS) stabilization method has been developed in fluid dynamics [15, 16]. Zienkiewicz *et al.* [17] have extended this technique to solid mechanics within explicit dynamic finite element formulation. This algorithm has been further developed to consider bulk metal forming problems [18].

In this paper, application of the CBS algorithm in solid mechanics will be reviewed. Basic continuum and discretized finite element equations are given. The constitutive model describing large elasto-plastic deformations of metals is presented. Finally a summary of an alternative stabilization algorithm based on the FIC is given [13].

Several numerical examples illustrating the performance of the CBS algorithm with linear triangles and tetrahedra are presented. Numerical examples range from 2D and 3D analysis of an impact problem to bulk forming problems. Numerical results obtained using the CBS method are compared with the results obtained with the FIC algorithm and with solutions using hexahedral elements based on a mixed formulation.

2. THE CBS ALGORITHM FOR SOLIDS

2.1. Continuous equations

The CBS algorithm for solids has been derived in Reference [17]. The algorithm obtained in fluid mechanics has been extended to solid mechanics by introducing an appropriate constitutive model for a solid material in split equations describing the solid material deformation.

The problem is governed by the Stokes equations. The Stokes equations do not contain convection terms, so the term ‘characteristic’ in the name of the algorithm CBS is not relevant. We maintain, however, the name CBS of the algorithm developed for fluid dynamics problem governed by the Navier–Stokes equations.

Large elasto-plastic deformations are considered with a small amount of compressibility allowed, as this generally is the case with large deformation behaviour of solids.

The equations expressing the momentum conservation are written as follows:

$$\begin{aligned}\rho \frac{\partial v_i}{\partial t} &= \frac{\partial s_{ij}}{\partial x_j} + \frac{\partial p}{\partial x_i} + b_i \\ \frac{\partial u_i}{\partial t} &= v_i\end{aligned}\quad (1)$$

where ρ is the density, v_i the velocity in the i direction, s_{ij} the deviatoric stress component, p the mean stress (or pressure), b_i the i component of body force and u_i the displacement in the i direction. Equations of motion (1) are completed with appropriate boundary conditions and constitutive equations for deviatoric part of stresses s_{ij} and pressure p . The elasto-plastic constitutive model with $J2$ plasticity is presented later on. The constitutive law for pressure is as follows:

$$\frac{1}{K} \frac{\partial p}{\partial t} = \frac{\partial v_i}{\partial x_i} \quad (2)$$

where K is the bulk modulus of the material. The boundary conditions prescribe velocities

$$v_i = \hat{v}_i \quad \text{on } \Gamma_v \quad (3a)$$

and tractions

$$t_i = \hat{t}_i = n_j (\hat{s}_{ij} - \delta_{ij} \hat{p}) \quad \text{on } \Gamma_t \quad (3b)$$

Application of a standard, Galerkin, finite element discretization of displacement \mathbf{u} , velocity \mathbf{v} and pressure p

$$\begin{aligned}\mathbf{u} &\approx \tilde{\mathbf{u}} = \mathbf{N}_v \tilde{\mathbf{u}} \\ \mathbf{v} &\approx \tilde{\mathbf{v}} = \mathbf{N}_v \tilde{\mathbf{v}} \\ p &\approx \tilde{p} = \mathbf{N}_p \tilde{\mathbf{p}}(t)\end{aligned}\quad (4)$$

to Equations (1) and (2), gives the discrete equations of mixed formulation, cf. Reference [1]

$$\begin{aligned}\mathbf{M} \frac{d}{dt} \tilde{\mathbf{v}} &= \mathbf{R}_v - \mathbf{f}_d - \mathbf{C} \tilde{\mathbf{p}} \\ \frac{d\tilde{\mathbf{u}}}{dt} &= \tilde{\mathbf{v}} \\ \mathbf{M}_p \frac{d\tilde{\mathbf{p}}}{dt} &= \mathbf{R}_p + \mathbf{C}^T \tilde{\mathbf{v}}\end{aligned}\quad (5)$$

In the above, $\bar{\mathbf{v}}$ and $\bar{\mathbf{p}}$ stand for the sets of unknown nodal parameters, the matrices are given by, cf. Reference [1]

$$\begin{aligned}\mathbf{M} &= \int_{\Omega} \rho \mathbf{N}_v^T \mathbf{N}_v \, d\Omega, & \mathbf{M}_p &= \int_{\Omega} \frac{1}{K} \mathbf{N}_p^T \mathbf{N}_p \, d\Omega \\ \mathbf{R}_v &= \int_{\Gamma_t} \mathbf{N}_v^T \hat{\mathbf{t}} \, d\Gamma + \int_{\Omega} \mathbf{N}_v^T \mathbf{b} \, d\Omega, & \mathbf{R}_p &= \mathbf{0} \\ \mathbf{f}_d &= \int_{\Omega} \mathbf{B}_v^T \mathbf{s} \, d\Omega, & \mathbf{C} &= \int_{\Omega} \mathbf{N}_v^T \nabla \mathbf{N}_p \, d\Omega\end{aligned}\quad (6)$$

where \mathbf{B} is the linear stress–strain operator matrix, stress deviator \mathbf{s} can be determined assuming arbitrary (isotropic) constitutive model.

With a fully incompressible material \mathbf{M}_p would be zero and this would not permit the application of time step procedures of the explicit type. Small compressibility allows us to adopt fully explicit solution scheme. In the explicit solution, the two matrices \mathbf{M} and \mathbf{M}_p are usually diagonalized.

The standard mixed formulation performs well for certain combinations of velocity and pressure discretization, which lead to finite elements satisfying BB stability conditions, like quadrilaterals and hexahedra with quadratic displacement (velocity) and linear pressure interpolations.

Elements not satisfying BB conditions, for instance linear triangles and tetrahedra with equal-order velocity and pressure interpolation, suffer volumetric locking. This difficulty can be overcome by the use of operator splitting procedures (or fractional step methods).

While not meeting all the BB requirements, the linear displacement constant pressure quadrilateral and hexahedral elements are usually stable and give very reliable results. They are standard elements of nearly all commercial ‘explicit’ finite element programs. They will serve in this paper as the basis for comparison for the performance of stabilized triangles and tetrahedra with linear displacement and pressure interpolations. Although our main interest is in stabilization of triangular and tetrahedral elements, the CBS algorithm will be applied to bilinear quadrilateral and trilinear hexahedral elements with equal-order displacement and pressure interpolation.

2.2. The fractional step method

In the fractional step method, the equations are split into parts. The sum of the parts, however, must be such that the original equations are always recovered. The split can be applied to discretized equations, cf. Reference [19]. Here we will follow a ‘classical’ procedure [15, 16], where the split is applied to the equations of continuum (1) and (2) following their time discretization using the generalized mid-point rule (or θ method). After temporal discretization the equations have the following form:

$$\begin{aligned}\rho \frac{v_i^{n+1} - v_i^n}{\Delta t} &= \frac{\partial s_{ij}^n}{\partial x_j} + \frac{\partial p^{n+\theta_2}}{\partial x_i} + b_i^n \\ \frac{u_i^{n+1} - u_i^n}{\Delta t} &= v_i^{n+\theta_3}\end{aligned}\quad (7a)$$

and

$$\frac{1}{K} \frac{p^{n+1} - p^n}{\Delta t} = \frac{\partial v_i^{n+\theta_1}}{\partial x_i} \tag{7b}$$

where $\Delta t = t^{n+1} - t^n$, n and $n + 1$ are consecutive time instants, and θ_j are generalized mid-point rule discretization parameters. Note that the deviatoric stress and body force terms in Equation (7a) are evaluated at different temporal points than the pressure. This is to facilitate the split introduced next. For an arbitrary variable ϕ , we have the following relationship:

$$\phi^{n+\theta_j} = (1 - \theta_j)\phi^n + \theta_j\phi^{n+1} \tag{8}$$

with $0 \leq \theta_j \leq 1$. In our case, θ_1 can vary between 0.5 and 1, while θ_2 and θ_3 can vary between 0 and 1. In all that follows we shall use $\theta_1 = 1$.

The momentum equation (7a) is rewritten in the following form:

$$\rho \frac{v_i^{n+1} - v_i^* + v_i^* - v_i^n}{\Delta t} = \frac{\partial p^{n+\theta_2}}{\partial x_i} + \frac{\partial s_{ij}^n}{\partial x_j} + b_i^n \tag{9}$$

and split into two equations:

$$\rho \frac{v_i^* - v_i^n}{\Delta t} = \frac{\partial s_{ij}^n}{\partial x_j} + b_i^n \tag{10a}$$

$$\rho \frac{v_i^{n+1} - v_i^*}{\Delta t} = \frac{\partial p^{n+\theta_2}}{\partial x_i} \tag{10b}$$

where the fictitious velocity v_i^* is called the fractional velocity. The fractional velocity is obtained from Equation (10a)

$$v_i^* = v_i^n + \frac{\Delta t}{\rho} \frac{\partial s_{ij}^n}{\partial x_j} + \Delta t b_i^n \tag{11a}$$

and the real velocity is calculated from Equation (10b) as

$$v_i^{n+1} = v_i^* + \frac{\Delta t}{\rho} \frac{\partial p^{n+\theta_2}}{\partial x_i} \tag{11b}$$

Substituting Equation (11b) into Equation (7b),

$$\frac{1}{K} \frac{p^{n+1} - p^n}{\Delta t} = \frac{\partial v_i^*}{\partial x_i} + \frac{\Delta t}{\rho} \frac{\partial^2 p^{n+\theta_2}}{\partial x_i^2} \tag{11c}$$

Finally, from the second of Equation (7a), we obtain

$$u_i^{n+1} = u_i^n + \Delta t v_i^{n+\theta_3} \tag{11d}$$

The CBS algorithm stated above consists of the following four steps:

- (i) Calculate the fractional velocity v_i^* from Equation (11a).
- (ii) Calculate the pressure p^{n+1} from Equation (11c).
- (iii) Calculate the real velocity v_i^{n+1} from Equation (11b).
- (iv) Calculate the displacement u_i^{n+1} from Equation (11d).

2.3. Finite element discretization

Introducing the finite element space discretization of pressure and velocities given by Equation (4) and applying the Galerkin method to Equations (11a), (11c) and (11b) leads to the following set of discrete equations:

$$\begin{aligned} \mathbf{M} \frac{\Delta \bar{\mathbf{v}}^*}{\Delta t} &= \mathbf{R}_v - \mathbf{f}_d \\ \frac{1}{\Delta t} \mathbf{M}_p (\bar{\mathbf{p}}^{n+1} - \bar{\mathbf{p}}^n) &= -\mathbf{C}^T \bar{\mathbf{v}}^n + \tilde{\mathbf{C}} \Delta \bar{\mathbf{v}}^* - \Delta t \mathbf{H} \bar{\mathbf{p}}^{n+\theta_2} - \mathbf{R}_p \\ \mathbf{M} \frac{\bar{\mathbf{v}}^{n+1} - \bar{\mathbf{v}}^*}{\Delta t} &= -\mathbf{C} \bar{\mathbf{p}}^{n+\theta_2} \\ \bar{\mathbf{u}}^{n+1} &= \bar{\mathbf{u}}^n + \Delta t \bar{\mathbf{v}}^{n+\theta_3} \end{aligned} \quad (12)$$

where the additional new matrices are defined as follows:

$$\begin{aligned} \Delta \bar{\mathbf{v}}^* &= \bar{\mathbf{v}}^* - \bar{\mathbf{v}}^n \\ \tilde{\mathbf{C}} &= \int_{\Omega} (\nabla \cdot \mathbf{N}_p)^T \mathbf{N}_v \, d\Omega \\ \mathbf{H} &= \int_{\Omega} \nabla \mathbf{N}_p^T \frac{1}{\rho_0} \nabla \mathbf{N}_p \, d\Omega \\ \mathbf{R}_v &= \int_{\Gamma - \Gamma_t} \mathbf{N}_v \mathbf{s} \, d\Gamma + \int_{\Gamma_t} \mathbf{N}_v (\hat{\mathbf{t}} - \mathbf{n} p) \, d\Gamma + \int_{\Omega} \mathbf{N}_v^T \mathbf{b} \, d\Omega \\ \mathbf{R}_p &= \int_{\Gamma_v} \mathbf{N}_p^T \mathbf{n}^T \bar{\mathbf{v}} \, d\Gamma \end{aligned} \quad (13)$$

Evaluation of the second integral in \mathbf{R}_v requires the ‘extraction’ of the pressure part from the prescribed traction on the part of the boundary Γ_t . This can be done taking the pressure from the previous time step as an estimation. A similar estimation must be made for the deviatoric stresses \mathbf{s} on the part of the boundary $\Gamma - \Gamma_t$ to calculate the first integral in \mathbf{R}_v . In a simplified algorithm, these troublesome calculations are avoided and the vectors \mathbf{R}_v and \mathbf{R}_p are evaluated according to the second of Equation (6). This simplification implies the non-physical boundary condition

$$\frac{\partial p}{\partial n} = 0 \quad \text{on } \Gamma \quad (14)$$

and introduces a certain error in the pressure. It can be demonstrated, however, that this error is localized to narrow boundary areas, cf. Reference [20]. This simplification is employed in the

numerical algorithm presented below. Using this form of the algorithm, one avoids computation of $\tilde{\mathbf{C}}$, as well as, avoids integrations of the projections of deviatoric stresses on the velocity boundaries, cf. Reference [17].

2.4. Solution algorithm

(i) Approximate velocity increment determination:

$$\Delta \mathbf{v}^* = \Delta t \mathbf{M}^{-1} (\mathbf{R}_v^n - \mathbf{f}_d^n) \tag{15a}$$

(ii) The pressure increment evaluation:

$$\left(\frac{1}{\Delta t} \mathbf{M}_p + \theta_2 \Delta t \mathbf{H} \right) \Delta \bar{\mathbf{p}} = - \mathbf{C}^T \bar{\mathbf{v}}^* - \Delta t \mathbf{H} \bar{\mathbf{p}}^n \tag{15b}$$

(iii) The velocity correction:

$$\Delta \bar{\mathbf{v}} = \Delta \bar{\mathbf{v}}^* - \Delta t \mathbf{M}^{-1} \mathbf{C} \bar{\mathbf{p}}^{n+1} \tag{15c}$$

(iv) The displacement update:

$$\bar{\mathbf{u}}^{n+1} = \bar{\mathbf{u}}^n + \Delta t \bar{\mathbf{v}}^{n+1} \tag{15d}$$

The algorithm presented can be used either in a semi-implicit form with an implicit solution of the pressure equation (15b) or in a fully explicit manner taking $\theta_2 = 0$. This paper presents results obtained with a fully explicit algorithm.

2.5. Elasto-plastic constitutive model

The constitutive model used in any analysis of metal forming process must properly represent complex deformation and elasto-plastic properties of the material. The elasto-plastic constitutive model used in our analysis is that presented in Reference [21]. In the description of large elasto-plastic deformations, the multiplicative decomposition of the deformation gradient tensor \mathbf{F} into its elastic \mathbf{F}^e and plastic part \mathbf{F}^p is assumed

$$\mathbf{F} = \mathbf{F}^e \mathbf{F}^p \tag{16}$$

The model is developed in a stress-free intermediate configuration, and then all the constitutive relationships are transformed to the deformed configuration.

In the deformed configuration, the following additive decomposition of the Almansi strain tensor \mathbf{e} into the elastic and plastic parts, \mathbf{e}^e and \mathbf{e}^p , respectively, is obtained:

$$\mathbf{e} = \mathbf{e}^e + \mathbf{e}^p \tag{17}$$

The Almansi strain tensor, and its elastic and plastic parts, \mathbf{e} , \mathbf{e}^e and \mathbf{e}^p , can be expressed by the deformation gradient tensor \mathbf{F} and its elastic part \mathbf{F}^e and plastic part \mathbf{F}^p in the following form:

$$\begin{aligned} \mathbf{e}^e &= \frac{1}{2} (\mathbf{I} - \mathbf{F}^{e-T} \mathbf{F}^{e-1}) \\ \mathbf{e}^p &= \frac{1}{2} (\mathbf{F}^{e-T} \mathbf{F}^{e-1} - \mathbf{F}^{-T} \mathbf{F}^{-1}) \\ \mathbf{e} &= \frac{1}{2} (\mathbf{I} - \mathbf{F}^{-T} \mathbf{F}^{-1}) \end{aligned} \tag{18}$$

The implementation of the general model has been simplified by the assumption that elastic strains are small, which for metals is fully justified. This allows us to assume a simple form of the elastic part of the free energy function ψ^e

$$\psi^e(\mathbf{e}^e) = \lambda \operatorname{tr}(\mathbf{e}^e)^2 + \mu(\mathbf{e}^e : \mathbf{e}^e) \quad (19)$$

where λ and μ are the Lamé constants. With this form of the elastic potential, the Kirchhoff stress tensor $\boldsymbol{\sigma}$ is obtained as

$$\boldsymbol{\sigma} = \frac{\partial \psi^e(\mathbf{e}^e)}{\partial \mathbf{e}^e} = \lambda \operatorname{tr}(\mathbf{e}^e) \mathbf{1} + 2\mu \mathbf{e}^e \quad (20)$$

In the present implementation of the model, the associated flow rule is assumed with the Huber–Mises yield criterion. The stress–strain curve is taken in the following form:

$$\sigma_Y = K(a + \bar{\varepsilon}^p)^n \quad (21)$$

where σ_Y is the yield stress and K , a and n are the material constants.

3. STABILIZATION BASED ON FIC

The FIC approach has been successfully used to derive stabilized finite element and meshless methods for a wide range of advective–diffusive and fluid flow problems [22, 23]. The same ideas were applied in Reference [13] to derive a stabilized formulation for quasi-incompressible and incompressible solids allowing the use of linear triangles and tetrahedra.

The basis of the FIC method is the satisfaction of the standard equations for balance of momentum (equilibrium of forces) and mass conservation in a domain of finite size and retaining higher order terms in the Taylor expansions used to express the different terms of the differential equations over the balance domain. The modified differential equations contain additional terms which introduce the necessary stability in the equations to overcome the volumetric locking problem.

3.1. Equations of motion

Within the framework of a FIC formulation, the equations of motion for a solid material are written as, cf. Reference [13]

$$r_i - \frac{h_k}{2} \frac{\partial r_i}{\partial x_k} = 0 \quad \text{in } \Omega, \quad k = 1, n_d \quad (22)$$

where n_d is the number of space dimensions of the problems (i.e. $n_d = 3$ for 3D) and

$$r_i := -\rho \frac{\partial^2 u_i}{\partial t^2} + \frac{\partial \sigma_{ij}}{\partial x_j} + b_i \quad (23)$$

In Equation (23), ρ is density, t is time, σ_{ij} are stresses, b_i are body forces, and h_k are characteristic length distances of an arbitrary prismatic domain where equilibrium of forces is considered. Equations (22) and (23) are completed with adequate boundary conditions and constitutive equations.

Employing a standard split of stresses into deviatoric and volumetric (pressure) parts, s_{ij} and p , respectively

$$\sigma_{ij} = s_{ij} + p\delta_{ij} \tag{24}$$

the governing FIC equations of the mixed displacement–pressure formulation can be obtained in the following form [13]:

$$-\rho \frac{\Delta v_i}{\Delta t} + \frac{\partial s_{ij}}{\partial x_j} + \frac{\partial p}{\partial x_i} + b_i - \frac{h_k}{2} \frac{\partial r_i}{\partial x_k} = 0, \quad \frac{\Delta u_i}{\Delta t} - v_i^{n+1/2} = 0 \tag{25a}$$

$$\frac{\Delta p}{K} - \frac{\partial(\Delta u_i)}{\partial x_i} - \sum_{i=1}^{n_d} \tau_i \frac{\partial r_i}{\partial x_i} = 0 \tag{25b}$$

where K is the bulk modulus, ε_v is the volumetric strain and τ_i are *intrinsic time* parameters given by

$$\tau_i = \frac{3h_i^2}{8G} \tag{26}$$

with G being the shear modulus. It can be noted that the value of τ_i deduced from the FIC formulation resembles for $h_i = h_j = h$ that of $\tau = h^2/2G$ heuristically chosen in other works [7].

3.2. Weighted residual forms

The residual r_i is split now as

$$r_i = \pi_i + \frac{\partial p}{\partial x_i} \tag{27}$$

where

$$\pi_i = -\rho \frac{\partial v_i}{\partial t} + \frac{\partial s_{ij}}{\partial x_j} + b_i \tag{28}$$

Note that π_i is the part of r_i not containing the pressure gradient and may be considered as the negative of a projection of the pressure gradient. In a discrete setting, the terms π_i can be considered belonging to a space orthogonal to that of the pressure gradient terms. This is similar to the stabilization procedure based on a SGS method suggested in References [10–12].

Finally, the weighted residual form of the governing equations is written in the form

$$\int_{\Omega} \delta u_i \rho \frac{\Delta v_i}{\Delta t} d\Omega + \int_{\Omega} \delta \varepsilon_{ij} s_{ij} d\Omega - \int_{\Omega} \delta u_i b_i d\Omega - \int_{\Gamma_t} \delta u_i \bar{t}_i d\Gamma_t = 0 \tag{29a}$$

$$\int_{\Omega} \delta v_i \left[\frac{\Delta u_i}{\Delta t} - v_i \right] d\Omega = 0 \tag{29b}$$

$$\int_{\Omega} q \left(\frac{\Delta p}{K} - \frac{\partial(\Delta u_i)}{\partial x_i} \right) d\Omega + \int_{\Omega} \left[\sum_{i=1}^{n_d} \frac{\partial q}{\partial x_i} \tau_i \left(\frac{\partial p}{\partial x_i} + \pi_i \right) \right] d\Omega = 0 \quad (29c)$$

$$\int_{\Omega} \left[\sum_{i=1}^{n_d} w_i \tau_i \left(\frac{\partial p}{\partial x_i} + \pi_i \right) \right] d\Omega = 0 \quad (29d)$$

The stabilization of the momentum equation is necessary in convection-dominated problems, this is not relevant for solid mechanics problems, so the additional terms involving the space derivatives of the characteristic lengths have been omitted in Equation (29a). On the contrary, the stabilization term given by the last integral is essential in Equation (29c).

3.3. Finite element discretization

Introduction of finite element discretization of the displacements, the pressure and the pressure gradient projection gives the following system of discretized equations:

$$\mathbf{M} \frac{\Delta \bar{\mathbf{v}}}{\Delta t} - \mathbf{R}_v + \mathbf{f}_d = \mathbf{0} \quad (30a)$$

$$\frac{\Delta \bar{\mathbf{u}}}{\Delta t} - \bar{\mathbf{v}} = \mathbf{0} \quad (30b)$$

$$\mathbf{C}^T \Delta \bar{\mathbf{u}} - \mathbf{M}_p \Delta \bar{\mathbf{p}} - \mathbf{L} \bar{\mathbf{p}} - \mathbf{Q} \bar{\boldsymbol{\pi}} = \mathbf{0} \quad (30c)$$

$$\mathbf{Q}^T \bar{\mathbf{p}} + \bar{\mathbf{G}} \bar{\boldsymbol{\pi}} = \mathbf{0} \quad (30d)$$

where the element contributions are given by

$$\begin{aligned} \mathbf{L} &= \int_{\Omega} (\nabla \mathbf{N})^T \boldsymbol{\tau} \nabla \mathbf{N} d\Omega, & \bar{\mathbf{G}} &= \int_{\Omega} \mathbf{N}^T \boldsymbol{\tau} \mathbf{N} d\Omega \\ \mathbf{Q} &= \int_{\Omega} (\nabla \mathbf{N})^T \boldsymbol{\tau} \mathbf{N} d\Omega, & \mathbf{f}_d &= \int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma} d\Omega \end{aligned} \quad (31)$$

where

$$\boldsymbol{\tau} = \begin{bmatrix} \tau_1 & 0 & 0 \\ 0 & \tau_2 & 0 \\ 0 & 0 & \tau_3 \end{bmatrix} \quad (32)$$

The matrices \mathbf{M} , \mathbf{M}_p , \mathbf{C} and \mathbf{R}_v are defined in Equation (6). In the discretization procedure the same interpolation has been assumed for all the discretized fields: $\mathbf{N}_v = \mathbf{N}_p = \mathbf{N}_\pi = \mathbf{N}$.

The consistent definition of the characteristic length parameters is still an open question. In advective–diffusive and fluid flow problems it is usual to accept that the characteristic length vector has the direction of the velocity vector (this is the so-called streamline upwind Petrov–Galerkin or SUPG assumption [24]). In the examples presented in this paper, we have obtained good results using a simpler definition of the characteristic lengths with $h_i = h_j = h_{\min}$, where h_{\min} is the smallest of the element (triangles or tetrahedra) heights.

3.4. Solution scheme

A four-step semi-implicit time integration algorithm can be derived from Equations (30a)–(30d) as follows:

(i) Compute the nodal velocities $\bar{\mathbf{v}}^{n+1/2}$

$$\bar{\mathbf{v}}^{n+1/2} = \bar{\mathbf{v}}^{n-1/2} + \Delta t \mathbf{M}^{-1} (\mathbf{R}_v^n - \mathbf{f}_d^n) \quad (33a)$$

(ii) Compute the nodal displacements $\bar{\mathbf{u}}^{n+1}$

$$\bar{\mathbf{u}}^{n+1} = \bar{\mathbf{u}}^n + \Delta t \bar{\mathbf{v}}^{n+1/2} \quad (33b)$$

(iii) Compute the nodal pressures $\bar{\mathbf{p}}^{n+1}$

$$\bar{\mathbf{p}}^{n+1} = [\mathbf{M}_p - \mathbf{L}]^{-1} [\Delta t \mathbf{C}^T \bar{\mathbf{v}}^{n+1/2} + \mathbf{M}_p \bar{\mathbf{p}}^n - \mathbf{Q} \bar{\boldsymbol{\pi}}^n] \quad (33c)$$

(iv) Compute the nodal projected pressure gradients $\bar{\boldsymbol{\pi}}^{n+1}$

$$\bar{\boldsymbol{\pi}}^{n+1} = -\bar{\mathbf{G}}^{-1} \mathbf{Q}^T \bar{\mathbf{p}}^{n+1} \quad (33d)$$

In above matrices, \mathbf{M} , \mathbf{M}_p , \mathbf{L} , \mathbf{C} , \mathbf{Q} and $\bar{\mathbf{G}}$ are evaluated at t^{n+1} and

$$\mathbf{f}_d^n = \int_{\Omega} [\mathbf{B}^T \boldsymbol{\sigma}]^n d\Omega \quad (34)$$

where the stresses $\boldsymbol{\sigma}^n$ are obtained by consistent integration of the adequate (non-linear) constitutive law.

Note that steps (i), (ii) and (iv) are fully explicit. A fully explicit algorithm can be obtained by computing $\bar{\mathbf{p}}^{n+1}$ from step (iii) in Equation (33c) as follows:

$$\bar{\mathbf{p}}^{n+1} = \mathbf{M}_p^{-1} [\Delta t \mathbf{C}^T \bar{\mathbf{v}}^{n+1/2} + (\mathbf{M}_p - \mathbf{L}) \bar{\mathbf{p}}^n - \mathbf{Q} \bar{\boldsymbol{\pi}}^n] \quad (35)$$

Obviously, the explicit solution is efficient if diagonal forms of matrices \mathbf{M}_p , \mathbf{M} and $\bar{\mathbf{G}}$ are used. The explicit solution is possible if certain compressibility is assumed, i.e. $K \neq 0$. If $K \rightarrow \infty$ pressure must be obtained using the implicit scheme given by Equation (33c).

4. NUMERICAL RESULTS

4.1. Impact of a cylindrical bar

The problem analysed is the impact of a cylindrical bar with initial velocity of 227 m/s into a rigid wall. The bar has an initial length 32.4 mm and initial radius 3.2 mm. Material properties of the bar are typical of copper: density $\rho = 8930 \text{ kg/m}^3$, Young's modulus $E = 1.17 \times 10^5 \text{ MPa}$, Poisson's ratio $\nu = 0.35$, initial yield stress $\sigma_Y = 400 \text{ MPa}$ and isotropic hardening modulus $H = 100 \text{ MPa}$. A time period of 80 μs has been analysed.

Figure 1 shows 2D and 3D solutions using triangular and tetrahedral elements based on equal-order interpolation for displacement and pressure—both solutions exhibit volumetric locking. Figure 2 shows correct numerical solution obtained using quadrilateral elements, a mixed displacement–pressure formulation with constant discontinuous pressure in each element. This

Figure 1. Final deformed mesh for standard displacement solution with locking: (a) 2D solution using axisymmetric triangular elements; and (b) 3D solutions using tetrahedra elements.

Figure 2. 2D explicit solution using mixed formulation with quadrilateral elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

solution is used as a reference of comparison for the CBS stabilized solution using triangular, tetrahedral, quadrilateral and hexahedral elements with equal-order displacement and pressure interpolation. The CBS results for triangles and tetrahedra are also compared to the results obtained using the alternative stabilized algorithm based on FIC. Results obtained using the CBS algorithm and quadrilateral elements with equal-order displacement and pressure interpolation are shown in Figure 3. Figures 4 and 5 show results obtained using triangular elements with the CBS algorithm. We can see that the solutions are locking-free, and the distribution and values

Figure 3. 2D explicit solution using the CBS algorithm ($\Delta t = 0.60\Delta t_{cr}$) with quadrilateral elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

Figure 4. 2D solution using the CBS algorithm ($\Delta t = 0.60\Delta t_{cr}$) with triangular elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

of the pressure and effective plastic strain are consistent with those obtained using quadrilateral elements as shown in Figure 2. The two cases of analysis with the triangular mesh have different time steps, taken as 0.6 and 0.15 of the critical time step, respectively. Influence of the time step has been studied. Figure 6 shows the results obtained with triangular elements with the FIC stabilization, with τ taken as $\alpha h^2/G$ with $\alpha = 0.01$. 3D solutions obtained using tetrahedra with the CBS and FIC stabilizations are shown in Figures 7 and 8, respectively.

Different 2D and 3D solutions have been compared in Figures 9 and 10. Figure 9 shows the pressure variation along the axis of symmetry and Figure 10 presents the pressure variation

Figure 5. 2D solution using the CBS algorithm ($\Delta t = 0.15 \Delta t_{cr}$) with triangular elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

Figure 6. 2D solution using the FIC formulation ($\alpha = 0.01$) with triangular elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

along the generatrix. Although the pressures generally agree there is some divergence especially at the end of the axis of symmetry (Figure 9), which could indicate that a certain error is introduced by the approximate treatment of the traction boundary conditions in the simplified split algorithm.

4.2. Sidepressing of a cylinder

A cylinder 100 mm long with a radius of 100 mm is subjected to sidepressing between two rigid plane dies. It is compressed to 100 mm. The material properties are the following: $E = 217$ GPa,

Figure 7. 3D using the CBS formulation with tetrahedral elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

Figure 8. 3D solution using the FIC formulation ($\alpha=0.01$) with tetrahedral elements: (a) deformed mesh; (b) pressure distribution; and (c) effective plastic strain distribution.

$\nu = 0.3$, $\rho = 7830 \text{ kg/m}^3$, $\sigma_0 = 170 \text{ MPa}$, $H = 30 \text{ MPa}$, friction coefficient = 0.2. The die velocity is assumed to be 2 m/s. Initial set-up is shown in Figure 11. A quarter of a cylinder was discretized with hexahedra or tetrahedra. Contact between the deformed material and die is treated using the penalty method.

Figure 12 shows the results obtained using hexahedrals mixed formulation with constant pressure and trilinear displacement interpolation. The results are shown in the form of deformed shape with distribution of the effective plastic strain and pressure. These results will be treated as the reference ones for other solutions. Results obtained using the CBS algorithm and hexahedral

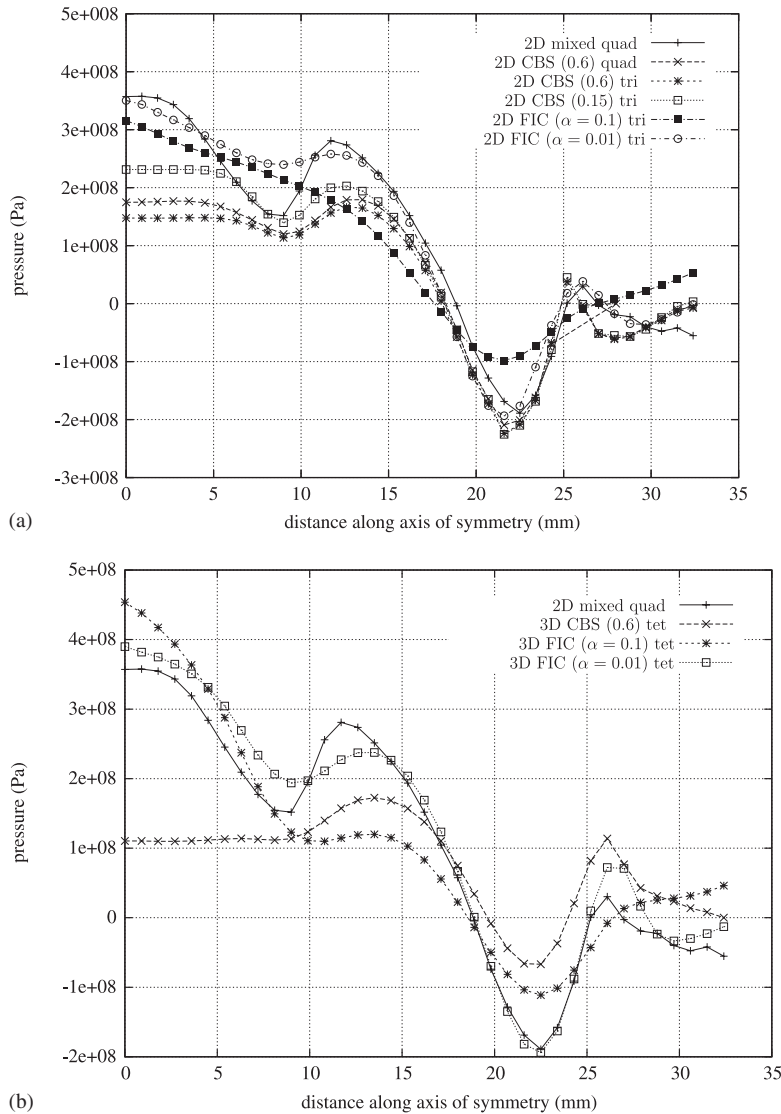

Figure 9. Pressure distribution along the axis of symmetry in: (a) 2D solutions; and (b) 3D solutions.

elements with equal-order displacement and pressure interpolation are shown in Figure 13. Figures 14 and 15 show the results obtained using the CBS algorithm for two different meshes of tetrahedra. The results obtained with the FIC stabilization are shown in Figure 16. Quite a good agreement can be seen between different solutions presented. Variation of pressure along the line ABCDEA defined in Figure 17 has been presented in Figure 18. Figure 18 confirms a good agreement between stabilized solutions with the reference solution.

4.3. Backward extrusion

Backward extrusion of a cylinder made of steel 16MNCr5 has been analysed. This is a benchmark example of the finite element program for forming simulation MARC/Autoforge [25]. The tooling and billet geometry are given in Figure 19(a). Initial material dimensions are the following: length 30 mm and diameter 30 mm. Punch of diameter 20 mm has a prescribed stroke of 28 mm. Material properties are as follows: Young's modulus $E = 3.24 \times 10^5$ MPa,

Figure 11. Sidepressing of a cylinder: (a) initial tetrahedral mesh; and (b) initial hexahedral mesh.

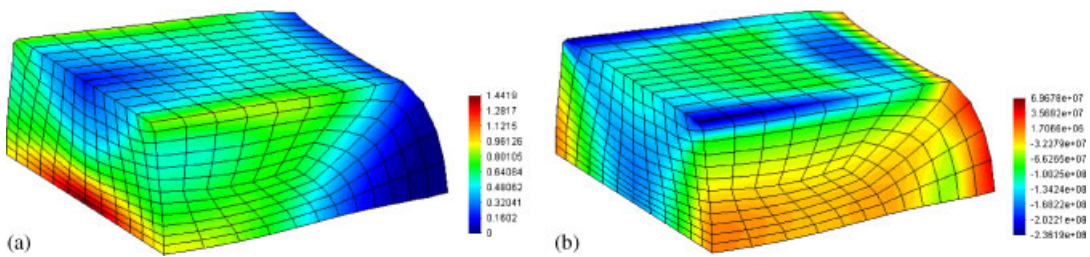

Figure 12. Sidepressing of a cylinder, mixed formulation, hexahedral mesh: (a) effective plastic strain; and (b) pressure distribution.

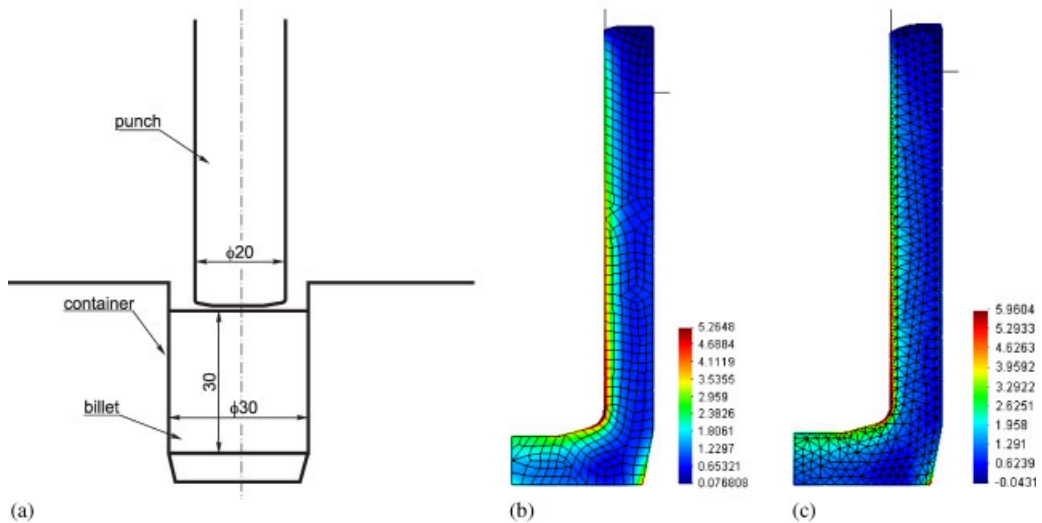

Figure 19. Backward extrusion: (a) geometry definition; (b) final deformed shape with effective plastic strain distribution, solution with quadrilaterals and mixed formulation; and (c) final deformed shape with effective plastic strain distribution, solution with triangles and the CBS algorithm.

Poisson's coefficient $\nu = 0.3$, material density $\rho = 8120 \text{ kg/m}^3$, yield stress $\sigma_{Y0} = 300 \text{ MPa}$ and hardening modulus $H = 50 \text{ MPa}$. Friction between the material and tools is defined by the Coulomb friction coefficient $\mu = 0.1$.

The simulation of the backward extrusion was carried out with remeshing employed to regenerate the meshes when element distortion was excessive. Figures 19(b) and (c) show the results in the form of the final deformed shape with the distribution of the effective plastic strain obtained using quadrilaterals and mixed formulation, and using triangles and the CBS algorithm, respectively. The results are in a good agreement with the solution given in Reference [25]. This example demonstrates use of the CBS algorithm in simulation of bulk forming processes.

5. CONCLUSIONS

The characteristic-based split algorithm provides the necessary stabilization for elements not satisfying BB conditions like equal-order displacement–pressure interpolation triangles, quadrilaterals, tetrahedra and hexahedra. The extension of the CBS algorithm to solid mechanics is straightforward. Its implementation in the explicit dynamic finite element program allows the simulation of solid mechanics problems with quasi-incompressible deformation of materials typical for bulk metal forming problems, for instance. The results obtained using the CBS algorithm are in quite a good agreement with the results obtained using other methods.

ACKNOWLEDGEMENTS

The authors are thankful to Professor O. C. Zienkiewicz for inspiration, continuous encouragement and many useful discussions.
